Between July 1916 and July 1917, when a war supply was being collected, the market for concentrate averaged \$73 per ton. On a 5% recovery it would require 20 tons of ore, at a mining and milling cost of \$1.80 per ton, to make a ton of concentrate. The royalty, usually on sub-lease, would be 15% instead of 10%. Thus the estimate would be:

Market price of concentrate.....	\$73.00
Royalty 15%	10.95

20 tons of crude ore at \$1.80 per ton ..	\$36.00
Allowance for depletion.....	\$26.05
	5.00
	\$21.05

Thus, thanks to the higher price of the metals, the profit was even better than in normal times.

The post-war profit per ton on a price of \$55 for 60% concentrate should be:

Market price of concentrate.....	\$55.00
Royalty 15%	8.25

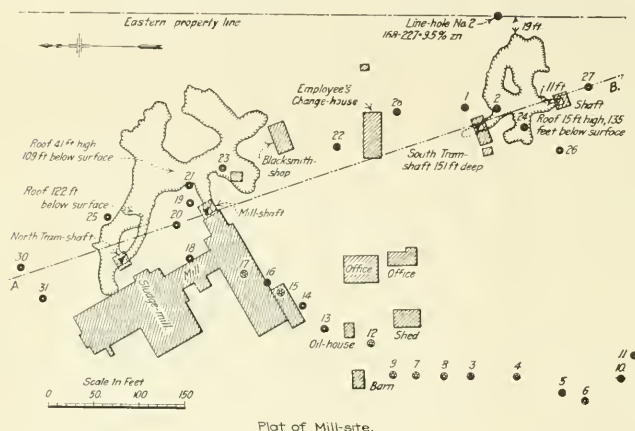

20 tons of crude ore at \$1.30 per ton ..	\$26.00
Allowance for depletion.....	\$20.75
	5.00

Profit\$15.75

Most of the local output is sold to the United States Steel Corporation's zinc plants at Denora, Pennsylvania, and Cherryville, Kansas. These take 3000 tons per week. Matthiessen & Hegeler, at La Salle, Illinois, take about 1000 tons each week. An equal amount goes to the Illinois Zinc Co. at South Chicago. The American Metal Co. buys 2500 tons weekly for its plant at Bartlesville, Oklahoma. The Grasselli Chemical Co., in West Virginia, is another important buyer. The

American Zinc, Lead & Smelting Co., at St. Louis, is in and out of the market irregularly. The United States Mining, Smelting & Refining Co. owns a group of small smelters in Oklahoma and Kansas; these buy a good deal of the local product. It is estimated that 21,000 retorts in the smaller smelters consume 7 tons of concentrate per retort per annum.

A good example of a winning enterprise is afforded by the Oklahoma Woodchuck, which is being operated by Mr. Burger as president for a company of New York capitalists. The lease of the 40 acres was acquired on April 25, 1917, for \$200,000 cash and a 15% royalty plus ten additional monthly payments of \$15,000 each making \$350,000 in money. A 200-ton mill was on the ground and has been more than doubled in capacity since

Plan of Mill-site.

Section on Line A-B.

FIG. 3. PLAN AND SECTION OF WOODCHUCK PROPERTY, SHOWING DRILL-HOLES AND STOPES

ing and milling \$1.10 per ton. The yield was \$24.75 per ton, thus:

Market price of concentrate.....	\$45.00
Royalty 10%	4.50
	\$40.50
14½ tons of crude ore at \$1.10 per ton.....	15.75
	\$24.75
Deduct amortization of ore-reserve.....	4.75
	\$20.00

Therefore the 40-acre tract should yield 40,000 tons of 60% zinc concentrate, and 8000 tons of 80% lead concentrate at a combined profit of \$20 per ton, making \$800,000.

FIG. 4
GEOLOGIC CROSS SECTIONS OF THE OZARK UPLIFT
After Buckley.

the purchase. The ground had been drilled at 31 points with results that indicated a tonnage of ore valued at several times the purchase price of the lease. This estimate has been confirmed by the work done during the summer.

On the accompanying plan and section (Fig. 3) are shown the drill-holes that justified the purchase of the Woodchuck property, also the mine-workings as they were last summer.

A 10-year lease on a 40-acre tract having at least two drill-holes in good ore is said to be worth \$50,000. "Five

holes in ore are worth \$10,000 apiece" was the dictum of a well-informed operator. A few examples of actual deals will be interesting.

1. 40 acres, 30 drill-holes, 1 mill, 2 shafts, 15% royalty. Price \$30,000.
2. 100 acres, 83 drill-holes, 3 mills, 5 shafts, 20% royalty. Price \$600,000.
3. 180 acres, 45 holes, no mill, no shaft, 15% royalty. Price \$250,000.
4. 560 acres on the outskirts of the district, 30 drill-holes, no mill, no shaft, 15% royalty. Price \$100,000.

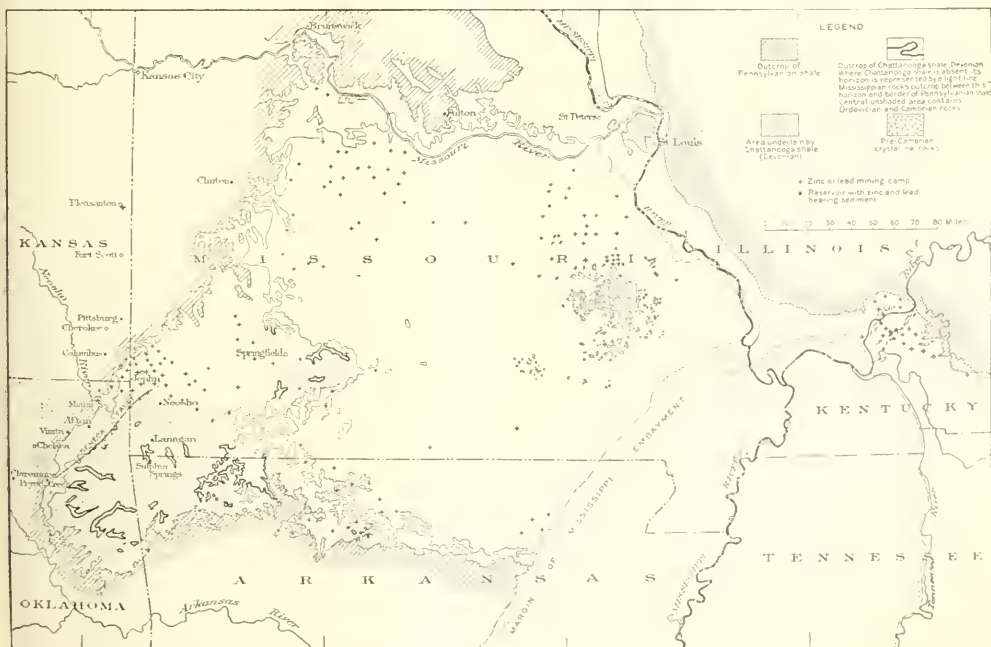

FIG. 5. MAP OF THE OZARK UPLIFT. U. S. GEOLOGICAL SURVEY

5. 20 acres, 9 drill-holes, no mill, 1 shaft, 25% royalty. Price \$125,000.

6. 20 acres, no drill-holes, no shaft, 15% royalty. Price, \$50,000.

7. 40 acres, 115 drill-holes, 1 mill, 4 shafts, 25% royalty. Price \$1,000,000 flat.

8. 320 acres, in the heart of the district, 72 drill-holes, 3 mills, 9 shafts, 12% royalty. Price \$1,250,000.

9. 300 acres, 350 drill-holes, 15 shafts, 6 mills and building 4 more, 7 to 12½% royalty. Price \$2,000,000. This property is yielding 500 tons of concentrate per week, so that the owner (L. S. Skelton) is making about \$1,000,000 net per annum.

In every case the mineral rights are held under a 10-year lease, subject to renewal, but as to that no assurance is given. It may be assumed that most of the operators expect to exhaust their ground within the decade.

The cost of existing activities in the Kopselter zinc districts may be estimated. It is probable that 1000 drills are⁶ at work averaging two holes per month, 300 ft. deep, at \$1.50 per foot. This represents \$900,000. I am informed that 167 mills have been built and that 100 of them are running. Estimating that each group of mining operators owning one of these mills is spending an average of \$15,000 per month, we get a monthly expenditure of \$1,500,000. Thus the total annual expenditure now being incurred in the district is about \$30,000,000. The mineral output in 1917 had a market-value of \$36,000,000.

ORE DEPOSITS. For the purpose of an article such as this, intended to give a general description of the region, it is not necessary to present much geologic detail. Viewed broadly, the rock structure is simple. The Kopselter zinc-mining region constitutes one of four mineral areas bordering the Ozark uplift, which is a dome of pre-Cambrian granite and other crystalline rocks thrust through a sedimentary series sloping from a maximum elevation of about 2000 ft. above sea-level to the plain, 1500 ft. lower, as shown by the accompanying cross-section (Fig. 4) borrowed from C. E. Siebenthal, whose study⁷ of this region is accepted as authoritative. The tilting of the sedimentary rocks is marked by anticlinal folds and by faults, which together have served to give direction to mineralizing solutions. The chief structural features are the Joplin anticline, the Seneca fault, and the Miami fault, all of which are shown on the map accompanying my previous article. See also Fig. 5.

The characteristic ore deposit of the Joplin district is the 'sheet ground,' the name given to nearly horizontal seams of blende and galena lying between layers of flint. These seams range from a fraction of an inch to several inches in vertical series, so as to form a workable thickness of ore-bearing ground 6 to 40 ft. thick. The flint formation is known as the Great Falls chert; it lies be-

tween beds of limestone, called the Mississippian, and is overlain by the shale and sandstone beds of the Pennsylvanian series, all Carboniferous.

In the Picher and Commerce districts the surficial formation is the Cherokee shale, of the Pennsylvanian; this overlies the Chester sandstone and limestone of the Mississippian, resting upon the Boone chert and limestone, at the base of the Mississippian. The removal of the Chester limestone, by solution, has caused the sandstone to settle upon the Boone chert so as to cause the sandstone and the chert itself to be fractured and brecciated. In this breccia the zinc ore has been precipitated along channels of solution that constitute 'runs'. The ore is found at depths ranging from 90 to 200 ft. depending upon the dip, the faulting, and the topography. The rock sufficiently enriched to be 'ore' is from 15 to 50 ft. thick and is usually limited by beds that have resisted fracture.

The methods of mining in the Joplin district are simple.⁸ In the first place the ore-bearing ground is nearly horizontal and from 2 to 20 ft. thick, so that it can be stoped for the full thickness by driving a heading under the roof and then blasting the bench that is made thereby. Fig. 1 is a rough sketch, showing the drill holes in dotted lines, and also the ore, in pockets and seams. The roof consists usually of a bed of flint two or three feet thick. The stopes have the appearance of big cellars with bays made by the several headings. Fig. 2 is a sketch of a mine in plan, showing how pillars are left to support the ground and how the ear-tracks reach out from the shaft. Pillars, 12 to 30 ft. thick, are left at intervals of 25 to 30 ft. Special care is taken to protect the shaft. The shafts—which are less than 300 ft. apart—have only one compartment, and are not provided with ladder-ways, the men ascending and descending in the 'can' or 'bucket'. The Joplin practice, as outlined above, is duplicated in the new Oklahoma zinc mines, for instance, as I saw it in the Netta. The ore is from 15 to 40 ft. thick. Where the ore-fractures and zones of brecciation are separated by intervals of barren rock, it is usual, of course, to leave these intervals intact for the support of the ground. The more nearly vertical arrangement of the ore, between hard beds of flint, causes the stopes to be high and narrower, but the general procedure is much the same. In leaving pillars, advantage is taken, as far as possible, of ore leaner than the average. Partly because of the thickness of the ore deposits, and partly because of the character of the roof, which is strong and will not break in the proper manner, it is not feasible to apply any modification of either the long-wall or the caving systems in these mines. The pillars at first are quite large in horizontal cross-section. After the ore has been followed to its limit in any direction the pillars are systematically robbed to the extent that the experience of the miners indicates as being safe.

⁶I am speaking of operations as they were in October last; since then the falling market has served to discourage prospecting.

⁷Bulletin 606, U. S. Geological Survey: 'Origin of the Zinc and Lead Deposits of the Joplin Region,' 1915.

⁸'Mining and Treatment of Lead and Zinc Ores in the Joplin District, Missouri.' By Clarence A. Wright. Technical Paper 41, U. S. Bureau of Mines.

The absence of share-dealing is a marked feature of mining throughout this region. To one engaged in obtaining information it is a wholly pleasant feature, because there is neither the reticence nor the discounting of truth that follow the gambling and the mis-representation that are part of share-peddling. The mines are owned and operated by small groups and syndicates, for the most part, and even where a corporation controls property any speculation in shares is prevented by the failure to list companies working these zinc-lead mines. I was informed that so much money had been lost by the public in the Joplin and Webb City stocks that the brokers of the New York Curb Association decline to list the shares of mining companies in these and adjacent districts. A few unimportant companies are listed on the Kansas City curb. It is probable, however, that a stronger reason for the absence of share-dealing is the fact that mining operations are conducted under leases of relatively short periods, decreasing the equity-value of the properties, but producing the excellent result of causing attention to be concentrated on the exploitation of the ore deposits, not on the pockets of the public. In consequence of these conditions it seems to the visitor that the business is conducted on a most satisfactory basis. The local industry shows how mining can be done vigorously and successfully without the intoxicant that has impaired the economic health of many rich mineral localities.

THE complex nature of the platinum-bearing ores of the Boss mine, in the Yellow Pine district, Clark county, Nevada, according to Fred A. Hale Jr., has presented many difficulties, but after extensive experimenting, a process has been evolved which bids fair to prove successful in the extraction of the metals. Owing to the inaccessibility of the mine and the high cost of labor and reagents, it was decided to erect the plant at Los Angeles. A separate corporation, known as the Palau Metals Co., was formed, and this company, headed by C. A. Overmire, entered into a contract with the Boss Gold Mining Co. for the exclusive treatment of its platinum-bearing ores. A plant of 300 tons monthly capacity was erected. The ore treated in the plant averages about 7% copper, 4% bismuth, 1.0 oz. platinum metals (platinum and palladium), 0.75 oz. gold, and 3.0 oz. silver per ton. It is crushed to 8-mesh at the mine before shipment. The crushed ore is dumped directly into bins from which it is fed to a 4 by 5-ft. Herman mill, which reduces it to 80-mesh. The pulp is elevated by a Frenier pump to 14 agitating tanks, where sulphuric acid is introduced to bring the solution to approximately 2%. The pulp is agitated for about 14 hr., the solution then decanted, and the pulp washed with water. The acid solution, which contains practically all the copper of the ore, together with about 20% of the platinum content, flows to tanks filled with scrap-iron, which precipitates the copper as cement copper, this containing also the platinum content of the solution. The cement copper from the precipitating tanks is collected period-

ically and forwarded to a refinery. In order to recover the remainder of the platinum, together with the gold and silver, the pulp is treated with two successive leaches of calcium chloride, the sulphuric acid having been previously neutralized with lime. No details are available for the exact method used in precipitating the precious metals from the calcium chloride solution. The process involves no roasting and all solutions are applied cold. The inventors of the process claim that the operations to date indicate an extraction of approximately 92% of the copper, and 96% of the platinum metals, gold, and silver. Over 90% of the bismuth content is also recovered and forms a valuable by-product.

Alaska Gold

Rumors to the contrary, Alaska Gold is not contemplating a shut-down, although under the adverse operating conditions of the past winter, accentuated by an insufficient supply of labor, the property has not in all months been able to show proportional fixed charges earned. In addition to 750,000 shares, Alaska Gold has \$3,000,000 6% bonds outstanding, semi-annual interest on which is due March 1 next. The amount of this semi-annual interest is \$90,000. There is likewise no truth in the rumor that a consolidation with the adjoining Alaska-Juneau is contemplated. Beyond informal talks between interested parties on both sides some two years ago, no official consideration has been given to a union of the two properties. In respect to ore disappointments, the expected values in Alaska-Juneau have been quite as far below original expectations as have been those in the Alaska Gold property. The results for January at Alaska Gold, showing an average value of ore extracted of but 90.3 cents per ton, established a new low record, the previous low points being 92c. in November 1915, and 94c. in April 1916. These figures compare with an anticipated recovery, when the property was originally offered to the public, of \$1.75 per ton. While the ore ran below 90c. per ton during the first 10 days of January, the headings in the final 10-day period averaged about \$1.16. In view of the fact that under normal operating conditions Alaska Gold can do better than break even, the management will continue operations in the hope of running into higher-grade ore. A shut-down of the property would paralyze business conditions in the Alaska mining district in which it operates, besides throwing out of employment a large number of its own men. Until conditions, therefore, become more desperate than at present, operations will continue. It is needless to say that the disappointments at the Alaska Gold property have been a great blow to managing director D. C. Jackling, who, however, consoles himself with the thought that those who have followed his mining judgment in the copper investment field have done so well that they will perhaps be generous enough to take philosophically the Alaska Gold failure.—Boston News Bureau.

Specific Heat

By JOHN ROGER

The specific heat of a metal is supposed to be the amount of heat necessary to raise the temperature of one pound 1° F., as measured by the amount of heat required to raise the temperature of one pound of water from 62° to 63° F. This is right and proper in determining how much heat is required to raise the temperature of a given weight of metal so many degrees, but when we wish to compare the specific heat of one metal with that of another, it shows no relative proportion whatever, as may be seen by comparing the specific heats of the various metals given in the accompanying table.

Metal	Atomic weight	Specific heat	Weight cu. ft.	Dia-magnetic resistance lb.	Tensile strength per sq. in.	Melting temperature, F.
Nickel	58.7	0.109	548	59.97	80,000	3,560*
Iron	55.9	0.113	480	55.58	60,000	3,260*
Copper	63.6	0.095	552	52.44	34,000	2,390*
Platinum	194.8	0.032	1,347	43.10	50,000	3,660*
Silver	107.9	0.057	655	37.33	36,000	2,210*
Gold	197.2	0.032	1,200	38.40	20,000	2,432*
Aluminum	27.1	0.214	167	35.1	20,000	1,675*
Zinc	65.4	0.095	436	41.42	6,000	1,240*
Tin	119.0	0.056	458	25.64	5,000	902*
Lead	206.9	0.031	709	21.97	3,000	1,085*
Antimony	120.2	0.051	421	21.42	1,000	1,270*

The explanation is a simple one, namely, equal weights of dissimilar metals are not equal quantities; equal quantities should be measured by equal specific volumes. Weight is not a property of the matter we weigh, but is a relationship, and is dependent on the composition and condition of the earth, the attracting body. The earth attracts different elements with different degrees of intensity, similarly a magnet attracts different elements with different degrees of intensity, but the relative forces of attraction do not in either case constitute measure of quantity. The intensity of the earth's attraction, or the relative weights, do not in any way indicate the relative physical properties of the metals. To compare the specific heats of the various metals by quantities of equal weight is to compare altogether unequal quantities of matter. To say that one cubic inch of platinum and about eight cubic inches of aluminum are equal quantities, because they weigh the same, is absurd on the face of it.

When we add heat to, say, one cubic inch of iron, it acts to decrease the force of the atomic attraction, increasing the temperature, but the weight, or the atomic weight, has nothing to do with the case, because we are dealing with atomic relationship. Whether it is assumed that the increased temperature represents increased vibration, or represents an increase in the force of atomic repulsion, the change is produced in either case against the resistance of the force of atomic attraction, and has nothing to do with the weight of the material.

We estimate the strength of a metal by the square inch, and the square inch is a proportion of the cubic inch. So we estimate the strength of the metals by proportions of equal volumes. When we add heat to the metal it decreases the strength by overcoming its force of attrac-

tion, so the proportionate relationship between the different metals must be a volumetric one. The weight of a metal does not in any way indicate its force of atomic attraction. It must be evident that the specific heat of a metal is proportionate to the change produced in the force of atomic attraction, and is therefore proportionate in the different metals to the intensity of the force of attraction as indicated by their absolute melting temperatures, equal absolute volumes of the metals being equal quantities.

That the gravity weights and atomic weights have no direct relationship to the specific heats, can be clearly shown thus: Assuming one cubic foot of hydrogen gas and one cubic foot of oxygen gas, each at 20 lb. absolute pressure, and 600° absolute temperature, the specific heat of the two volumes will be practically the same, and when expanded through, say, 5° of temperature they will each develop the same amount of work, although their gravity weights and their atomic weights are in each case in the proportion of about 1 to 16.

When we deal with atomic relationship we deal with the action of one atom on another, and the atomic mass, or true atomic weight, is the force with which two atoms attract each other, this force decreasing with each degree of rise in temperature from zero, passing through the solid, liquid, and vapor to the true gaseous state, where the force of attraction ceases, and the change is, in a general way, proportionate in the different metals when dealt with by equal specific volumes.

In dealing with compounds, these rules do not always hold good, as the actions of dissimilar elements on each other under the influence of heat are varied and complex, as are all the actions and reactions of chemistry, and temperature is only one of the phenomena. The accompanying table gives specific heats by equal weights and diamagnetic resistance (specific heats by equal volumes) as compared with the tensile strengths and absolute melting temperatures of the commoner metals. The tensile strengths are misleading, as they should be estimated at a temperature of zero to conform closely with the absolute melting temperatures. The tensile strengths are also largely dependent on the structural condition of the material. The figures are necessarily all irregular, as none of the quantities are accurately known, and the comparisons are not parallel in any two cases. The different metals also, no doubt, act differently under an increase of temperature, as the table would seem to show; still the relationship is too pronounced to admit of doubt that, for comparison, specific heat should be dealt with by equal specific volumes of the metals and not by equal weights. Unfortunately we know very little as to what constitutes absolute volume, and this also adds to the irregularity of the figures.

DOMESTIC PYRITE ore is now selling for 28 to 30c. per unit of contained sulphur. These quotations apply to concentrates at eastern mills. This is shipped to plants as far in the interior as Middle-West points where sulphuric acid is made.

FIG. 4. ROASTER BUILDING DURING CONSTRUCTION

Photo by R. E. Price

The Humboldt Roasting-Plant

By A. A. WATSON

The Consolidated Arizona Smelting Co., at Humboldt, Arizona, is erecting four Wedge mechanical roasting-furnaces, each 22½ ft. diam., having seven hearths for roasting and one for drying, equipped with individual Cottrell dust-precipitators designed by the Western Precipitation Co. The charge to be treated will consist partly of flotation concentrate, a product of the company's Humboldt mill, partly of custom concentrate, and the remainder ¼ to ½ in. crude ore from the Consolidated Arizona Smelting Co.'s Blue Bell mine.

The capacity of the plant, when the present equipment is completed, will be 600 tons of wet charge per 24 hours, or 150 tons per furnace per 24 hours, producing a calcine containing 8% sulphur. In the design provision has been made for doubling the size of the plant as soon as other units of the smelter are enlarged.

As the flow-sheet shows, the concentrate is taken from the Portland filters up an inclined belt-conveyor to a horizontal belt-conveyor running over two 600-ton storage-bins. Another inclined conveyor brings ore from

the crushing-plant to a horizontal conveyor, running over two 600-ton bins adjacent to the concentrate-bins. In planning this arrangement the need for additional bins has been kept in mind, in order that any number of them may be built in the future without radical changes to the present equipment. The ore and concentrate are distributed into the different bins by means of traveling trippers on the horizontal conveyors running over the top of the bins. The ore and concentrates are taken from the bins by Stephens-Adamson apron-conveyors, which feed a horizontal belt-conveyor operating beneath the bins. This horizontal conveyor, after leaving the storage-bins, passes underneath the custom-concentrate bins, which bins are filled directly from the railroad cars. After passing the last bins, the conveyor is provided with a Merrick weightometer, which weighs the mixed charge of ore and concentrate before it is delivered to the roaster-plant.

An inclined conveyor takes the charge to the top of the building, where a horizontal conveyor and tripper

distributes it into a 100-ton bin opposite each furnace. The charge is then fed by means of a Webster Manufacturing Co.'s apron-conveyor, which is driven from the furnace drive. The calcined product leaving each furnace drops into an 18-ton firebrick-lined hopper. From these hoppers the calcine is fed by gravity into standard-gauge cars and hauled to the reverberatory furnaces.

The gases from the roasting-furnaces are carried upward through two 3-ft. flues to the duplex Cottrell treaters, where the dust is precipitated and collected in hoppers beneath, the clear gases escaping through a 4-ft. stack 30 ft. high. The flue-dust collected in the Cottrell hoppers is conveyed by means of a Webster 10-in. helioid conveyor to the end of the building, where it drops

through a chute into a hopper similar to the calcine-hoppers.

The electric energy used for dust-precipitation will be derived through two Westinghouse 15-kva., 60-cycle, 250 to 100,000-volt transformers, the high-tension side of which is connected through two Western Precipitation Co.'s standard mechanical rectifiers; the rectifiers being rotated in synchronism with two Westinghouse 15-kva., 60-cycle, 250-volt motor-generators, which supply the primary current for the step-up transformers.

The Cottrell precipitators consist of two-compartment sheet-steel chambers, containing forty 12 in. diam. by 16 ft. long steel tubes or receiving electrodes per compartment. The double compartment permits repairs to be made on half of the precipitator without stopping

FLOW-SHEET OF ROASTER PLANT

the roaster. In each of the above tubes is suspended a No. 3 Triumph chain, which serves as the discharge-electrode. One terminal of the rectifier is connected to the chain, which is insulated, and the other to the tube, the same being grounded.

The precipitation of dust takes place as follows: The solid particles carried by the gases passing upward through the tubes are electrified with a charge of like sign as the chain, and are drawn to the tube. In a like manner a small portion of the particles are charged to

minimum. The roaster-building proper is of steel construction, measuring 65 ft. square and 85 ft. high to the bottom chord of the trusses. A 6-ton Otis freight-elevator runs to the top floor. The building is to be covered entirely with corrugated steel, to prevent loss in dust. The arrangement of the conveying and transmission machinery has been made as simple as possible, allowing ample working space around all the moving parts.

The arrangement for handling material is such that operating costs will be as low as possible to obtain for a plant of this size. Two of the roasters went into operation in December. Fig. 4 shows a photograph of the roaster-building under construction on November 14, 1917.

Fig. 3. CALCINE-CAR

opposite polarity and drawn to the chain. A rapping device is provided to jar the particles loose from the tubes and chains. The freed particles drop in a mass to the hoppers beneath the tubes.

Fig. 1 shows the general arrangement of the smelter. Fig. 2 illustrates the Cottrell plant. Fig. 3 is a drawing of the calcine-car in use.

The El Paso Bridge & Iron Works furnished and is erecting the steel building and treaters, amounting to approximately 550 tons of structural steel and plate. All belt-conveyors used in connection with this plant are 16 in. wide and the speed is 300 ft. per minute. They were furnished by the Jeffrey Manufacturing Co. The lengths range from 25 to 600 ft. between centres of head and tail pulleys. All gears, bearings, etc., for the conveyors and apron-feeders are of the same size and interchangeable, thus reducing the stock of repair-parts to a

DELICATE qualitative tests for certain metals are described by E. M. Chamot and H. I. Cole ('Jour. Ind. & Eng. Chem.'). Cleanse wool fibre with alcohol and ether; then soak over night in a 1% solution of NaOH; wash, and dip 6 times alternately in solutions of 10% zinc acetate and 10% sodium sulphide, pressing out the excess but not washing; dry by pressing between filter paper. Zinc sulphide wool-fibre thus made is sensitive to 0.001 mg. of copper. The NaS should be freshly made by passing H_2S through a solution of NaOH until it will yield no precipitate with $MgCl_2$. Place a drop of the solution to be tested on an object slide, add a drop of HCl, introduce into the drop a zinc-sulphide wool-fibre about 5 mm. long, and examine under the microscope; a straw-yellow color indicates tin, lemon-yellow arsenic or cadmium, orange antimony, reddish brown bismuth, brown or yellow-brown platinum, copper, mercuric mercury, or antimony, and sometimes cobalt, iron, manganese or nickel. The color observed varies with the amount of the metal present. A check against standard solutions of the indicated metals would seem likely to aid in the color discriminations.

IODINE recovery at the Chilean nitrate plants is thus described by A. H. Rogers and Hugh R. van Wagenen in the Transactions of the American Institute of Mining Engineers. All caliche, apparently without exception, contains iodine. It is believed to exist as calcium iodate, lautarite. In leaching, this is converted to sodium iodate, which is very soluble, and accumulates in the mother-liquor in the leaching-circuit. When the concentration of the iodate in the liquor reaches 10 to 20%, the liquor is delivered into the tanks in the iodine house and treated with a strong solution of acid sodium sulphite. The sodium sulphite is manufactured by first deflagrating sodium nitrate with coal and then circulating a strong solution of the resulting crude sodium carbonate, sal natron, through towers, into which the fumes of burning sulphur are led. The sulphite reduces the iodate, precipitating iodine, which is allowed to settle and, after decanting, the clear liquid is filtered off and the iodine is caked in a cheese-press; this is sublimed in a coal-fired still, and condensed in a string of sewer tile.

Determination of Non-Sulphide Copper

By CHARLES E. van BARNEVELD and EDMUND S. LEAVER

*Experiments with the sulphur di-oxide method were made with the following requirements in mind: (1) the method must be applicable to a wide range of ores and must be thoroughly reliable and rapid; (2) copper sulphides, especially the more easily decomposed chalcocite, must not be affected by the reagent used; and (3) metallic iron must not affect the determination. The results showed conclusively that cuprite, melaconite, malachite, azurite, chrysocolla, and metallic copper, when finely pulverized, are readily and completely soluble in sulphur di-oxide solution (sulphurous acid). Copper sulphides are not attacked, no matter how finely pulverized, nor how long the time of contact. The two essential features of the method are: (1) fine pulverization in order to completely free the particles of copper minerals from the gangue; (2) the powdered mineral must be kept in suspension by shaking or rolling during the period of lixiviation.

The procedure in the sulphur di-oxide method is as follows: Place 2 grammes of pulp, ground to a fineness of 100 to 150 mesh, in a bottle, add 100 cc. of a 3% solution of sulphur di-oxide. Seal the bottle and agitate by rolling from thirty minutes to two hours. Filter, wash the residue with sulphur di-oxide solution; add the washings to the filtrate, which will contain in solution all the copper oxides, carbonates, and silicates, and all the metallic copper. Add 5 to 10 cc. of nitric acid; boil down to 20 cc.; dilute with distilled water to 150 cc., and determine the copper by the electrolytic method in the usual way. The residue from filtration contains the unaltered and undissolved copper sulphides. In the experimental work the copper present as sulphide was separately determined in order to check the determination of the oxidized copper. Ordinarily this step would not be necessary. In analyses of the low-grade porphyry copper ores of the South-West, the sulphides may be readily decomposed and all the copper dissolved by proceeding as follows: To the residue add 5 cc. of sulphuric acid and 10 cc. of nitric acid, and boil until dense white fume appears; add 5 cc. of nitric acid, and dilute with distilled water to 150 cc.; then determine the copper by the electrolytic method. This method of determining copper in the residue is not suited for heavy sulphide ores containing interfering bases, and for such ores standard methods should be used.

Although sulphur di-oxide solution may be readily purchased, it is decidedly unstable; hence the solution should be prepared in the laboratory as needed. Small quantities are easily made by adding moderately strong

sulphuric acid to scrap copper tinned on one side; the resulting sulphur di-oxide gas is absorbed in water. For continuous work it is better to purchase liquid sulphur di-oxide in steel cylinders and drums, which are obtainable in sizes holding from 6 to 200 lb. In the first experiments at the Tucson station the sulphur di-oxide gas

APPARATUS FOR PREPARING SO_2 SOLUTION

was introduced directly into the bottle containing the water and pulp. Much loss of gas resulted and the procedure was otherwise unsatisfactory. Later the simple apparatus shown in the illustration was evolved. The absorption tower *a*, 43 in. long, made of $\frac{3}{4}$ to 1-in. glass tubing, and filled with broken hard-burned fireclay, is set at an angle of 75° between two glass bottles, *b* and *d*, of 3 to 5 gal. capacity, the bottle *b* being placed about five feet above the other bottle. The tower is open at the top, and is sealed at the bottom with a plug of sealing-wax, *c*, through which the small glass tubes extend. The

*Abstract: Technical Paper 198, U. S. Bureau of Mines.

upper bottle, *b*, contains distilled water, which is siphoned into the upper end of the absorption tower, the flow being regulated by a stop-cock, *f*. A cylinder, *c*, (holding 6 to 50 lb.), containing liquid sulphur di-oxide is connected to one of the glass tubes extending into the absorption tower. On opening the valve of this cylinder the liquid sulphur di-oxide issuing from the valve is gasified by the reduction in pressure, and passes into the tower, where it is absorbed by the water from bottle *b*, converted into SO₂ solution of the desired strength, and caught in the stock-bottle *d*. This apparatus gives satisfaction. With but little attention a 3% solution of sulphur di-oxide may be produced at the rate of three litres per hour. The cylinder containing liquid sulphur di-oxide, indicated in the illustration, may be replaced with a gas generator.

Considerable variation as regards strength of solution and time of contact will be necessary in treating ores from different localities. In general, a solution containing 3% SO₂ should be used. With some ores solutions as low as 0.75% SO₂ will do the work. Merely introducing the pulp into the solution, shaking the bottle for a few minutes, and letting it stand, will not dissolve the copper; constant agitation is essential. For a small number of tests a bottle-agitating machine will give satisfactory results. For analytical work, where large numbers of samples are run, as in a mine laboratory, a bottle-rolling machine will be found best. The time of contact necessary to completely dissolve the oxidized copper minerals was found to vary from one-half to two hours.

To determine the strength of the sulphur di-oxide solution an adaptation of a well-known reaction is recommended, which is based on the fact that introducing either weak or concentrated sulphurous acid into a solution of iodine will result in the complete oxidation of the sulphur di-oxide. Prepare an iodine solution by dissolving 16.8 gm. of potassium iodide in distilled water, adding 8.4 gm. of pure re-sublimed iodine, and shaking until the iodine is completely dissolved. The more concentrated the potassium-iodide solution, the more readily will the iodine dissolve. Bring the solution to the proper strength by adding enough distilled water to make 1 litre. Then standardize the solution by the thio-sulphate method, using starch indicator. The determination is made as follows: To a measured quantity of standard iodine solution add slowly, with constant stirring, the proper volume of sulphur di-oxide solution. So regulate the volume of the iodine solution used that the mixture always contains a decided excess of iodine over the quantity required to oxidize the sulphur di-oxide being added. An excess of sulphur di-oxide causes the solution to clear and to lose its dark red color. If an excess of sulphur di-oxide is added the determination is spoiled, and the test should be repeated with fresh SO₂ solution and a larger quantity of iodine solution. Thus, there is a direct ratio between the strength and quantity of sulphur di-oxide solution and the quantity of standard iodine solution. For solutions containing

one to three per cent sulphur di-oxide 1 cc., and for weaker solutions 20 cc., of standard iodine solution should be used. The mixture is then titrated by the thio-sulphate method to determine the quantity of iodine remaining in the mixture. The difference between this quantity and the total quantity of iodine represents the iodine used in oxidizing the sulphur di-oxide. The strength of the sulphur di-oxide solution may then be calculated according to the formula:

The method is applicable alike to high-grade and low-grade ores. The manipulation is simple and the possible sources of error are few. One chemist can keep a 6-unit electrolytic outfit working to full capacity on porphyry ores. Any metallic copper present would be reported with the oxidized copper. If a separate determination of metallic copper is considered necessary this may be made by amalgamation, preferably in an amalgamated copper pan.

Cost of Excavation for Mill

The following figures give the cost of excavation for the mill of the Holden Mining & Milling Co., at Tuscarora, Nevada, under the superintendency of J. D. Hubbard.

Character of ground, about two feet of tight top-soil (clay, earth, and broken rock), the rest being rock that had to be blasted. All material moved an average distance of 100 ft. Cost of common labor \$4 per shift of eight hours. Miners at \$4.50 per shift. Teams, two horses and driver, at \$7 per shift. Dynamite (40%) cost 26c. per lb. Detonators, \$2 per 100. Fuse, 75c. per 100 ft. Material removed:

	Cu. yd.
Lower bench	650
2nd bench	707
3rd bench	634
4th bench	362
Upper bench	20
Total	2,373

Costs:

Labor, November 1917.....	\$1,535.75
Labor, December 1917.....	2,924.50
Labor, January 1918.....	317.00
	<hr/>
Explosives	110.75
Wear on tools.....	36.00
Blacksmithing and general expense.....	145.00
Superintendence	298.00
	<hr/>
Total	\$5,367.00

Cost per cu. yd. = \$2.26127.

As a comparison it may be noted that the average prices on this class of work on contract basis for the large railroad companies was from \$2.50 to \$3.50 per cu. yd., and when price of labor was \$2.25 per day, powder 12c. per lb., and a 10-hour day obtained.

The East Tintic District, Utah

By BENJ. F. TIBBY

Tintic lies about 65 miles south of Salt Lake City and on the west slope of the Tintic mountains. This district, of which Eureka is the principal town, is one of the oldest in Utah. Recent important developments have brought into prominence the eastern part of the district.

The rocks of the area consist of a series of Paleozoic sediments and a variety of Tertiary igneous masses. The structure of the Tintic mountains, within the limits of the important mines, is that of a simple syncline with an axial trend in a general north-south direction. The axis of the fold pitches, and to the south the axial plane has a westerly dip. The sedimentary rocks are limestone and quartzite, with minor intercalations of slate and shale. The limestone has been differentiated into three principal formations, and designated from younger to older as the Humbug, Godiva, and Eureka members. Under these is the quartzite. Igneous rocks are present as sheets of rhyolite and andesite, together with an intrusive monzonite, the last having a close genetic connection with the orebodies. The sedimentary beds on the west limb of the syncline have a steep angle of dip, sometimes overturning, while the beds on the east limb have a more gentle dip, rarely exceeding 40° . The trough of the syncline forms the highest topographic features and may be taken as a rough line of division between two distinct portions of the Tintic district, namely, the eastern and the western.

Ore is found in the sedimentary rocks, in the igneous rocks, and at the contact of the two, but the economic importance of the first far overshadows the others. The workings of the large and more important mines are in the limestone beds of the western limb of the syncline, or

in close proximity to its axis on the eastern limb. The less steeply inclined beds of the eastern limb are almost completely covered by a cap of rhyolite, the limestone showing in only a few places, either as isolated islands in the sea of rhyolite or where erosion has cut through the igneous sheet and exposed the limestone at lower elevations.

The principal bodies of lead-silver ore that have made the district famous as a dividend payer are those that occur as metasomatic replacements in the limestone. The deposits in the igneous rocks, or at the contact of the igneous and sedimentary rocks, are of secondary importance. In the sedimentary rocks an extensive series of north-south fractures, parallel with the axis of the syncline, and of vertical or nearly vertical dip, are closely associated with the genesis of the ore. Because of the greater amount of development work most of these fractures have been found on the western limb of the syncline, but they also constitute an important geological feature of the eastern limb.

The genetic importance of these fracture zones has been a subject of disputation. Guy W. Crane has said: "In an earlier report on the Tintic district, reference is frequently made to the north-south fissures, which, it is contended, have governed the course of the ore channels. The writer's investigations have not confirmed the common presence of such north-south fissures within the ore zone, but, on the contrary, have gone to show that practically all the major faulting of fissures in the district is of the nearly east-west or transverse type." George W. Tower and George Otis Smith[†] hold that the north-south

[†]Trans. A. I. M. E., Vol. LIV, p. 351.

fractured zones have played an important and principal part in the ore deposition. The recent developments at the Tintic Standard* show plainly this marked general north-south fracturing associated with the ore, while up to this time, at least, no transverse fissuring of importance has been noted. The ground-water level in the sedimentary rocks stands near the 1200-ft. level of the Bullion-Beck mine. The 1300-ft. level of the Tintic Standard mine is still above ground-water level. Considering the district as a whole, completely oxidized ores extending downward for several hundred feet from the surface and partly oxidized minerals form the principal ores of the deepest workings. Leaching processes in nearly every case have removed effectively all but a mere vestige of the metallic minerals from the surface, and such outcrops as are visible present a barren and uninviting appearance. Geological deductions have been the means of uncovering many bonanzas. The original discovery and point of sinking the operating shaft for one of the principal mines was on a fissure in the limestone that offered no trace of valuable mineral at the surface and the first ore encountered was below the 200-ft. level. Quoting from the above-mentioned report of the U. S. Geological Survey: "In the Bullion-Beck, the ore does not extend above the 80-ft. level. In the Gemini it is not found above the 200-ft. level and not in paying quantities above the 400-ft. level." Speaking of the extensive orebodies of the Eureka Hill and Bullion-Beck mines the report says: "The only known croppings of these orebodies occur on the hill slopes just south of the Eureka Hill shaft. The Silver Gem orebody does not appear at the surface." Referring to the Gemini mine: "The ore occurs in fractures parallel to and crossing the bedding of the limestone. They have a vertical range of 100 to 400 ft., rarely exceeding 600 ft. in length. They do not appear at the surface." These statements have reference to the ore occurring in the limestone, but it is a matter of fact that the outcrops in the igneous rocks also are for the most part barren. The contact of the limestone with the igneous rocks is conspicuous by the presence of iron oxides carrying little or nothing of the more valuable metals. A large amount of this iron-bearing material has been shipped to the smelter as flux.

The orebodies in the limestone were formed prior to the effusive overflow. While, as noted, the extent of the fracturing on the eastern limb of the syncline is not so great as on the western limb, there is no reason for believing it does not exist in the limestone beneath the igneous capping. Whether these fractures will prove as prolific a channel for mineralizing solutions as elsewhere remains to be demonstrated.

The area of East Tintic is traversed by a series of north-south outcrops that stand above the rhyolite country-rock, and are, therefore, later than the fractures that produced the orebodies in the sedimentary rocks. These outcrops differ from the rhyolite in composition and by

*19th Annual Report U. S. Geol. Sur., Part III, 'Geology and Mining Industry of the Tintic District, Utah.'

*See map on page 345.

virtue of their hardness are easily observable above the surface mantle. If valuable minerals were ever present in these outcrops they have been removed by leaching. No development of any consequence has been done on the outcrops to prove their value in depth.

It is a sound geological deduction that the eastern fold of the syncline should prove a place for ore, but in most cases prospecting in the underlying sedimentary rocks was precluded by the cost of penetrating the overlying rhyolite cap. Several years ago a portion of this area was tested by churn-drilling; later an attempt was made to apply this method of work to the patenting of lode-claims, it being held that it was a most satisfactory method of development. The Land Office decided otherwise, but later, after a contest extending over two or three years, the contention of the mine-owners was allowed and drill-holes were ruled to come within the scope of development work necessary to secure a patent on lode-mining claims. Until the last two or three years mining in the East Tintic district was small in scope, and while a little ore had been uncovered in several places, it remained for the Tintic Standard Mining Co., under the persistent efforts and able direction of E. J. Raddatz, to open an orebody of substantial proportions, and thereby prove definitely what had heretofore been only an attractive geological deduction. The geological conditions in the Tintic Standard are similar to those in the western part of the district, the orebodies being associated with the north-south fractures. Development of the Tintic Standard orebody was effected through a shaft together with a series of drifts and winzes. This did not afford an economical method of bringing the ore to the surface, so a new shaft was begun and has been completed to a depth of 1300 ft., a connection having been made at this level with the old workings. A peculiar fact in connection with the sinking of this new shaft was that within 250 ft. of the collar the westerly dipping limestone outcrops, and yet the shaft penetrated 550 ft. of the rhyolite before entering the limestone. The last 750 ft. of sinking was entirely in the limestone. In the upper portion of the limestone the beds had their characteristic westerly dip. In the lower part of the shaft the broken and shattered condition of the limestone concealed any traces of the bedding. The lowest station of the new shaft is at 1260 ft. From this level a drift was driven 200 ft. eastward, penetrating a new orebody. The ore that is being shipped at the present time is principally sulphide, an unusual condition compared with other mines in the district. There is, however, an abundance of oxidized ore. An electric hoist and an electrically driven compressor have been installed. For the week ended February 9, thirteen cars of ore was shipped from the Tintic Standard. The stope from which this ore was taken is already seven sets wide, two sets high, and 130 ft. long, with all sides of the stope still in ore. Samples show an average of 70 oz. silver, \$5 gold, 12% lead, and 3% copper. Without question this discovery is the most important that has been made in the Tintic district for many years.

REVIEW OF MINING

NEW YORK

A. I. M. E. MEETING.—EXCHANGE WITH CHILE.—POTASH PRODUCTION.

Technical papers at the A. I. M. E. meeting last Tuesday were of a generally high standard, and sessions were well attended. In one instance much time was taken up in demonstrating a newly-patented apparatus of limited application, although of some interest. Impression was created in some quarters that the facilities of the Institute had been taken advantage of for the purpose of advertisement, and the question might be asked as to how a line could be drawn if all patentee members were to take a similar course. A number of pertinent questions were put as to the applicability and operation of the method, and this served to indicate that the patentee had avoided much expense and trouble by using the Institute and its bulletins as a medium for publicity rather than the usual trade channels. In another instance one of the papers submitted dealt with the results of small and large-scale tests carried out for the apparent purpose of disproving the correctness of the theories supposed to underlie the operation of a patented machine. The author apparently proved his point by a drastic reversal of normal operation; but in this instance the patentee was absent, and no discussion bearing on the important points raised in the paper was submitted. An interesting series of views of Bolivian tin mines was given later in the afternoon by Mark R. Lamb, and the usual smoker was held in the evening. This was a successful reunion. Representatives of the British Army and the French Commission gave brief addresses, and were received with acclamation. The policies and attainments of the more important Government bureaus at Washington were ably championed by their representatives. At a meeting of the Woman's Auxiliary held on Wednesday morning, Dr. Vernon Kellogg of the U. S. Food Administration, drew attention to the compulsory rationing in England at the present time, and voluntary rationing here, and stated that Mr. Hoover's 'honor' ration of $2\frac{1}{2}$ lb. of meat per week was $1\frac{1}{2}$ lb. in excess of the English ration per capita, and that whereas $\frac{3}{4}$ lb. of sugar was allowed here only 2 oz. per week per capita was allowed in England. Compulsory rationing must inevitably follow here if the honor ration is not voluntarily complied with, the speaker asserted. A distinguishing feature of Wednesday's sessions was the attention directed to and interest displayed in papers dealing with employment and sociological problems, for which T. T. Read may be accorded much credit. A paper was presented during the morning by Dr. T. Darlington, formerly Health Commissioner for New York City, dealing with illness among industrial workers and losses incurred thereby by their employers. A number of additional points of interest were brought out in the subsequent discussion. In the afternoon a new precedent was set when Mrs. Gilbreth formally presented a paper written by her husband (Major Frank M. Gilbreth, the well-known author of 'Motion Study'), and charmed those present by a short address during which she dealt with the problem of the crippled soldier and the valuable service that he might be allowed to give if suitable work were found him. Mrs. Gilbreth concluded by an appeal to engineers and managers to consider the question; and to do all they could to anticipate having to

provide employment for such men wherever opportunity occurred. Her address was illustrated by lantern-slides showing how a number of phases of human effort in industry could be capably controlled by limbless men. Other important aspects of the employment problem were discussed, including the wastage due to unnecessary labor turnover—estimated to cost the country between two and five billion dollars annually—education of employees, and housing. The intrinsic value of an education among all employees was demonstrated by a representative of the National Association of Corporation Schools, an institution that co-operates with pre-existing schools of all kinds and aims to promote the specialized training and to insure the co-ordination necessary for industrial and commercial efficiency. The Association now contains a membership of 118 prominent firms in the leading industries of the country, representing a capitalization of over \$3,000,000,000. The importance of the housing problem was dealt with by a representative of the National Housing Association, who described the benefits to the companies, which had expended an amount equivalent to one-third of one per cent of their payroll to provide adequate and satisfactory accommodation for employees. The cost of replacing men in factories was estimated at from \$40 to \$50 per head, and this fact was emphasized as an incentive to the provision of adequate housing facilities. Government action was illustrated by the fact that \$50,000,000 was recently set aside for building workmen's dwellings to house shipyard employees. Another bill for a like amount was to be introduced shortly, the money to be loaned to private firms unable to finance the necessary extensions. The usual dinner was held at the Hotel Biltmore in the evening, and was well attended. Bainbridge Colby, Director of the U. S. Shipping Board, was the speaker of the evening; in his introductory remarks he deprecated the retiring Institute president's somewhat critical attitude. On Thursday there was an all-day excursion to Princeton, where members of the Institute were guests of the University. Luncheon was served in Proctor Hall of the Graduates College, and was followed by an interesting address by President Hibben, who, after dealing with the importance of engineering and technics in the progress of the War, criticized the philosophy that pretended that what was right today was false tomorrow. Right must remain right, and not be susceptible to modification by military necessity or by the exigencies of the situation. He insisted that we should eliminate further reference to the destiny of the country as the ultimate victor and consider the unpleasant but obvious truth that, for the present at least, Germany is winning the War. To achieve her final triumph the United States must put forth her full strength in those vital and influencing factors of technical education, technical training, technical initiative, and inventiveness. Philip N. Moore replied on behalf of the Institute. The afternoon was spent in visits to University buildings and laboratories.

Weakening of British financial influence in South America is seen in the official recognition by the Chilean government of dollar exchange. This action is one that has caused much comment and favorable criticism. Export duties on nitrate shipped from Chile may be liquidated by drafts on New York in United States dollars, and it is hoped that the concession may be extended so that import duties into Chile may be met

by the same currency. Previously only sterling bills drawn on London were accepted, which involved circuitous transactions and cumulative commission costs.

Optimistic forecasts with reference to America's independence of German supplies of potash formed the basis of a recent address by a vice-president of the Du Pont Nitrate company, who intimated that his company had achieved production at the rate of 10,000 tons per annum of a product containing 25% of potassium nitrate, equivalent to 1200 tons of K₂O. It was stated that there were 200 oficinas or nitrate plants in Chile capable of producing a like amount, by which a total of 240,000 tons per annum might be arrived at—a figure capable of enlargement, it was stated, by more exact methods of beneficiation, to 720,000 tons. This latter amount was apparently the nearest that could be obtained by any stretch of the imagination to approximate Germany's sale before the War, amounting to 900,000 tons. As an addendum to this somewhat remarkable prognostication it may be pointed out that the estimated number of operating plants in Chile is over-estimated by about 100%, and that much of the caliche contains practically no potash.

An air-mail service will be established between New York, Washington, and Philadelphia within the next few months, it is reported. Three hundred pounds of first-class mail will be carried by each machine. The service will commence with one round trip per day, and tenders have been invited by the Post-Office for the machines required.

CRIPPLE CREEK, COLORADO

DRAINAGE-TUNNEL.—ORE-DUMPS.—ISABELLA.

Two shifts are working in all headings of the Roosevelt drainage-tunnel. The main opening is being extended toward the Golden Cycle shaft of the Vindicator company on Bull hill, and drifts are being driven to Portland No. 2 shaft on Battle mountain, and the Cresson main shaft on Raven hill.

The tunnel was advanced 112 ft. in the main heading during February, while the Portland cross-cut was driven 93 ft. and Cresson drift from the tunnel-level, 112 ft. Flow of water through the measuring-weir at the tunnel portal now measures 3575 gal. per minute.

With reference to sale of mine-dumps by Stratton's Cripple Creek Mining & Development Co., mentioned in the issue of March 2, other applications have been filed, but will not be acted upon until returns are received from initial shipments sent out under existing contracts. Under sale conditions, 75c. per ton is to be paid the Stratton estate for the ore and a deposit of \$75 is required prior to shipment of each 100 tons. The dumps must be moved entirely. No less than 2700 tons was moved during January from the Economic dump, on the western slope of Squaw mountain, and shipped to the Golden Cycle plant at Colorado Springs. Average gold value was \$3.10 per ton.

W. P. H. Leasing Co. has made a rich strike in the W. P. H. mine of the United Gold Mines Co., on Ironclad hill. At the bottom or 900-ft. level, a fault-vein, recently exposed, is from 4 to 8 ft. wide, and outside of a white talc streak, is averaging 2 oz. per ton. Initial shipment gave \$38.10 per ton. The talc streak, 2 to 4 in. wide, is filled with calaverite crystals, and is worth many dollars per pound.

Annual report of Isabella Mines Co. shows that the Bull Hill properties of the company were operated at a loss during 1917. Total receipts amounted to \$143,357, and disbursements \$163,660, a deficit of \$20,303. Company has a cash balance of \$38,798, with supplies valued at \$3250. At present, in addition to company work, there are 15 sets of lessees. More ore is now being mined by lessees than for some time.

Dividends for March declared by Cripple Creek companies are as follows: Gresson Consolidated, 10c. per share, total, \$122,000; Golden Cycle M. & R. Co., 3c., \$45,000; and Granite

Gold Mining Co., 2c., \$16,500. All are payable on March 10, and total \$183,500.

LEAD, SOUTH DAKOTA

MANAGNESE.—NEW AERIAL TRAM AND MILL.

DEADWOOD.—Deadwood Lead & Zinc Co. continues erecting 10-stamp concentrating plant, and expects to have it ready early this summer. Buildings are complete and installation of machinery proceeds. Ore containing gold, silver, lead, and zinc will be treated. Development of mine continues.

LEAD.—Initial shipment of 31 tons of manganese ore made by J. F. Street from the Fremont property contained 49.6% manganese, 1.82% iron, 3.17% silica, and 0.03% phosphorus. Total value was \$1671. Erection of a concentrator to dress lower-grade material is being considered.

TERRY.—Mogul company has completed installation of aerial tram from mine to mill ore-bins. By new arrangement ore is drawn through chutes at the working-adit, from where it goes to a tram pocket at the portal. Main adit has advanced 600 ft. and is below the ore-zone, making use of raises and chutes advantageous. Tram has been placed in commission and eliminates railroad transportation.

LORDSBURG, NEW MEXICO

ACTIVITIES IN THE STEINS, BURRO SPRINGS, AND LORDSBURG DISTRICTS.

There is more mining activity at Steins than for some time. Several operators are extracting ore for shipment and others are doing development work. Plans are being made to erect ore-bins and more adequate shipping facilities here.

Fred. P. Davy has taken a lease on the Silver Hill mine, three miles south of Steins, from Cloudman and Bradford. Ore contains lead and silver. Shipments will be made to the Ozark Smelting & Refining Co., at Coffeetown, Kansas, the freight rate from Steins being \$6.50 per ton. Cloudman and Bradford have several cars ready for shipment and Mr. Davy plans to sub-lease some of his ground where ore is developed, so that regular shipments may be made. He plans to install a compressor and machine-drills at his lease.

Trigear and Conolly continue to work the Merrimack mine. Mr. Rice, of Douglas, Arizona, is operating the Rice property.

Mr. Thompson, of Miami, Arizona, is shipping some lead ore from the Clifford group.

The McGee company continues development.

After being practically dormant for a number of years there is again activity at Burro Springs, on the west side of the Burro mountains, 30 miles north of Lordsburg, where J. C. Brock has developed an excellent gold-silver-lead group of claims. Vane Gould, the McGear Brothers, Ed. Baker, and Will Layne are operating the mine with Mr. Brock, and will soon have a shipment of ore which will probably be sent to El Paso. Work is being done by hand, but as soon as boiler repairs are made the owners plan to use power throughout. The mine is equipped with practically enough machinery for a treatment plant, and this is planned by Mr. Brock if water is encountered during development. There is considerable new mining machinery available. This property has not been worked for shipping for many years, but now stands good chances of coming to the front.

In the Lordsburg district, the 85 Mining Co. is to cease mining operations for about a month in order to install a new hoist and do development prior to starting its new mill.

The Atwood mine operators have changed the name of their company to the Boston-Emerald Mining Co. The only work being done at present is keeping the water down in the Atwood shaft. It is planned to have complete machinery and to begin work about March 25.

TINTIC, UTAH

LUCKY SHEPHERD, CHIEF CONSOLIDATED, AND McCRYSTAL MINES AFFAIRS.

Lucky Shepherd mine in West Tintic district is to be reopened, under control of W. D. Rawson of the Tintic Delaware nearby.

Ore sales of Chief Consolidated Mining Company in 1917 totaled \$1,554,714, less \$1,127,316 expenditure, \$152,409 to various properties, and \$309,452 for dividends. Balance at end of 1916 was \$477,295, and \$262,394 at end of 1917. Dividends to date total \$925,392.

The four McCrystal mines—Gemini, Godiva, Eureka, and

owners, or to take anything for which they have not a clear title, but they cannot but realize that many of the claims now so carefully guarded were open to re-location when they commenced taking up mineral ground in that section a few years ago.

Ore shipped from Imperial lead mine, 10 miles west of Tintic, assayed 1.1 oz. silver, 40.35% lead, 6% iron, and 2.1% zinc. Six earloads were sent to the smelter.

LUCIN.—Ore assaying up to \$235 per ton in silver and copper has been opened by the Lucin Copper M. & M. Co. in an adit. This property contains 8 claims.

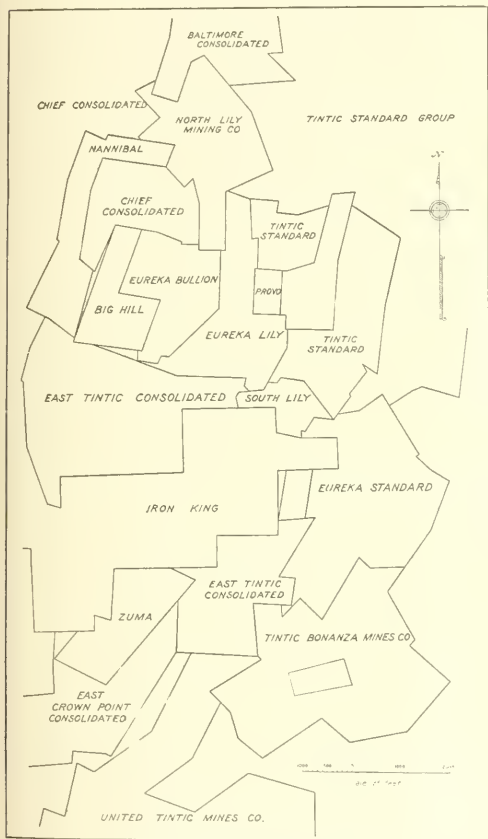

HOUGHTON, MICHIGAN

DEEP SHAFT WORK OF CALUMET & HECLA

The Red Jacket and Tamarack No. 5 vertical shafts of Calumet & Hecla are to be used to more advantage as soon as possible. These offer possibilities for great saving in operation and further economies in hoisting ore. The Red Jacket has a capacity of 3000 tons daily; this is not half utilized at present. There are six compartments; two for ore, one for bailing water, when necessary, one for supplies, and one for men. The shaft is straight to the 31st level, or bottom, nearly a mile deep. Levels are measured on the conglomerate angle shafts. From the bottom of Red Jacket shaft there is a long cross-cut, running parallel to the lode, and to the north of the shaft. From this point the company continues to mine from the rich 'five forties', and there are ore-reserves in that section, tributary to the Red Jacket shaft, that will require at least 15 years' work to extract at present rate. This north opening also permits working the rich conglomerate under No. 3 Tamarack, formerly known locally as the North Tamarack mine. Notwithstanding the great depth, and the slope shaft, this ore is handled at a cost not as high as that of the inclined shafts operated in the old way.

All of the Hecla and South Hecla shafts on the conglomerate lode of the Calumet & Hecla mine are deep. According to the last annual report No. 6 shaft was 7574 ft., 133 under the 79th level, and No. 7 was 7977 ft. or 140 ft. under the 80th level. Both are deeper at this time. At the South Hecla, sinking No. 8 was discontinued at 6120 ft., and at No. 9 and 10 the depth is 8132 ft., 142 ft. under the 82nd level. A drift has been started from No. 5 shaft, Tamarack, in the amygdaloid, 200 ft. from the foot-wall of the conglomerate, which is looked upon by miners as the preliminary step toward underground preparation to handle ore from at least four shafts through the Red Jacket shaft. Ore from the Hecla and South Hecla shafts, below their present depth on the 31st level, could easily be handled in this manner, and these shafts could then be permanently bottomed and all rich pillars and arches extracted. These shafts today present a deep mining problem that appears to offer a probable solution by the utilization of the motor-tram to either No. 5 Tamarack or Red Jacket shaft for haulage to surface. Application of this idea would release rich ore that is tied up in these long inclined shafts. Present cost of maintenance of Hecla and South Hecla shafts is very heavy. In No. 8 shaft, for instance, where sinking was suspended at the 63rd level, it is possible to take out arches and pillars from five levels per year. Practically none of this work has been done at shafts 6, 7, 9, and 10.

Tamarack No. 5 is 1200 ft. distant from the Red Jacket shaft. The reason the drift from this shaft was started in amygdaloid was for safety purposes only. At this depth a conglomerate drift would be out of the question. Electric haulage from various underground points to the vertical shafts is quite successful. Storage-battery locomotives are used entirely. In addition to the application of this idea to Hecla and South Hecla shafts there seems no reason why No. 2 shaft of the Tamarack mine should not be so equipped. At present it is generally believed that plans have not been worked out to a point where Calumet & Hecla is ready to make them public.

PART OF THE TINTIC DISTRICT, UTAH

Ridge & Valley—are operating under favorable conditions. The first has 100 lessees at work, and is developing at 1700-ft. depth. A joint pumping scheme is worked with the Ridge & Valley. Godiva has 20 men, mostly employed on 1200-ft. level.

In order to quiet title to ground in the eastern end of the district, Chief Consolidated has filed suit at Provo against the Central Standard Mining Co. (formerly Canyon Sliding), asking to be adjudged owner of four claims on which it is alleged the defendant company has encroached in making a survey for patent. There will probably be other suits in that area made known by the Chief Consolidated. Officials of this company state that they have no desire to make trouble for claim-

PLATTEVILLE, WISCONSIN

SUMMARY OF RESULTS IN ZINC REGION DURING FEBRUARY.

Zinc miners will long remember the past winter, the worst ever experienced. January snow and ice hampered operations in February, when there was a considerable car shortage, a coal famine, and bad roads. Additional to these burdens were further advances in price of powder and steel, hoisting cable was unobtainable, power companies demanded increased rates, tax collecting by town authorities, and low prices for zinc ore. Sales of ore from mines to smelters were light in February, the weather not being responsible entirely, but largely due to the market. Lead ore was steady at \$85 per ton throughout the month. Shipments were only 385 tons, out of stocks estimated at 2500 to 3000 tons. Gross extraction of mine-run ore was 13,423 tons, and net deliveries to smelters were 7273 tons.

Shipments of ores from mines to smelters direct and from mines to ore-dressing plants were as follows in February:

District	Zinc, lb.	Lead, lb.	Pyrite, lb.
Benton	18,122,000	288,000	\$26,000
Mifflin	2,882,000	140,000
Galena	2,468,000	88,000
Linden	1,318,000	68,000	530,000
Hazel Green	530,000
Cuba City	520,000	1,934,000
Highland	420,000
Platteville	192,000
Dodgeville	174,000
Shullsburg	110,000	126,000
Total	26,736,000	710,000	3,290,000

The labor situation was much relieved because of disorganized conditions. In the Linden district alone more than 200 miners were thrown out of employment, many of whom found employment at other points. Some new producers were started in the Hazel Green and Shullsburg districts, and no trouble was experienced in recruiting working forces. Building operations in the Cuba City district and at Linden enabled mechanics to find ready employment. While weather conditions made road improvement difficult, many operators took advantage and hedged soft stretches with 'charts' from the mills, that will help when the real spring thaw, now near at hand, commences. Established railroad schedules were being better observed toward the close of February. Prominent operators think that the heavy output of late in 1917 will be regained slowly this year.

MANILA, PHILIPPINE ISLANDS

BENGUET CONSOLIDATED COMPANY'S RESULTS IN 1917.

Little mining news is available from this Territory, so that an abstract of the above company's report for the past year should be of interest. The mines are at Antamok, Benguet, and C. M. Eye is superintendent.

	December	1917
Ore treated, tons.....	1,939	20,427
Gold content	\$32,033	\$363,762
Average per ton	16.32	17.80
Loss as dissolved metal.....	203	3,078
Loss as undissolved metal.....	3,056	43,508
Tailing loss in solution, per ton of tailing discharged	0.11	0.15
Tailing loss in undissolved metal per ton tailing discharged	\$1.57	\$2.12
Extraction, per cent.....	90.00	87.10

There were sent to the Mint at San Francisco 156 bars, weighing 23,279 oz., containing 14,799 oz. gold and 4444 oz. silver. The bullion was 636 fine in gold and 190 in silver.

Estimated value in bullion shipped, \$309,444, and total indicated saving \$317,176. The value of slag and matte on hand is sufficient to cover difference between this figure and value of bullion, with enough over to bring the production for the year to \$325,000. No account is taken in monthly production record of silver content of the ore, which materially swells the market value of bullion, slag, and matte.

Four dividends of 5% and one of 2½% were paid in 1917, amounting to P225,000, and approximately P100,000 capital expenditure was made.

MEXICO

GENERAL NEWS OF THE REPUBLIC.

MEXICO CITY.—During the last six months of 1917 the Department of Industry and Commerce issued 320 mining titles, mostly for exploitation of gold, silver, and copper; though a number included lead, zinc, iron, etc. These new titles were distributed as follows: Sonora, 117; Nuevo Leon, 45; Chihuahua, 31; Durango, 26; Jalisco, 15; San Luis Potosi, 13; Zacatecas, 11; Hidalgo, 10; Michoacan, 10; Coahuila, 9; Guanajuato, 7; Sinaloa, 6; Oaxaca, 5; Puebla, 5; Nayarit, 3; Queretaro, 3; Tamaulipas, 3; Lower California, 3; Mexico, 2; Federal district 1. It will be observed that the greater portion are in the States of Sonora, Durango, and Chihuahua, which are widely declared by misinformed periodicals to be in a state of complete unrest, says 'The Oasis' of Nogales, Arizona.

The government of Michoacan has issued instructions to the municipal authorities of the State to proceed immediately with the distribution of unoccupied lands among the people wishing them, in order that no time may be lost in preparing for the coming crop. This distribution will be subject to future regulation by the Agrarian Commission and to arrangement regarding their purchase from the owners or their rental therefrom. Congress of the State of Mexico will probably adopt the same law governing the use of unoccupied lands in that State, that was recently adopted by the National Chamber of Deputies for the Federal district and the territories. This law provides for the allotment of such lands to those desiring to make use of them for agricultural purposes.

It is expected that by March 1 the exhibitions of natural and manufactured products, authorized some time ago, will be opened in all of the consulates in the United States and Canada. Similar exhibitions will also be established in various European cities.

One of the large petroleum companies has offered to supply all dependencies of the National Government with gasoline and other oil products at 20% less than the market rate when in bulk, and at 15% when in packages. The offer has been accepted.

The Cananea Consolidated Copper Co. has been notified that unless it complies with the terms of a concession granted that concern for the construction of various railway lines within the State of Sonora within a reasonable time, it will be nullified.

Some time ago a number of locomotives from the National lines were sent to the United States to be repaired, facilities of Mexican shops being overtaxed. These engines are now being returned in full working order.

The second Workingmen's Congress has been called to meet in Saltillo, capital of Coahuila, at an early date. It will be held under the auspices of Governor Espinosa Mireles, and it is expected that much good will result, as was the case with the first session.

At a meeting of the Council of Technical Education held recently in Mexico City, it was decided that the preparatory school for women should be supplied with all the elements for female education in various lines.

In the six months ended December 31, 1917, the national mint turned out P20,700,000 in gold and silver coin of various denominations.

THE MINING SUMMARY

ALASKA

JUNEAU.—Alaska Gold Mines Co. reports as follows for the four quarters of 1917:

	Fourth	Third	Second	First
Tons milled	532,699	523,871	642,683	541,093
Gross value, per ton....	\$1.06	\$1.01	\$1.112	\$1.207
Yield	0.8608	0.8150	0.8988	0.997
Tailing	0.205	0.1915	0.2127	0.2102
Extraction, per cent....	80.7	80.69	80.85	81.06
Value recovered	0.8608	\$0.8150	\$0.8988	\$0.997
Net operating cost....	0.7901	0.7983	0.7210	0.788
Profit per ton.....	0.0707	0.0167	0.1778	0.209
Value bullion and conc.,	\$458,545	\$426,954	\$577,616	\$539,487
Profit	37,684	8,735	114,234	113,043

Charles Hayden, president, stated that, taking the year's operations as a whole, Alaska Gastineau earnings were sufficient to meet interest on debenture bonds and notes payable of Alaska Gold Mines. Earnings for the third and fourth quarters of the year were, however, at a rate considerably below the accruing interest requirements for the periods, and a continuance through 1918 of conditions that prevailed in those quarters would leave the company without necessary balance of income or available cash resources with which to continue payments of interest on its bonds. Last week it was decided not to pay interest due.

Alaska Juneau Gold M. Company's results during past 8 months were as under, according to Boston News Bureau:

Month	Tons	Assay	Extraction	Milling	Mining	General
1917	per day	per ton	tion, %	per ton	per ton	per ton
June ..	1,639	\$0.8103	70.0	\$0.713	\$0.3660	\$0.036
July ..	1,874	0.9610	76.0	0.651	0.2765	0.118
Aug. ..	2,486	1.2569	78.7	0.349	0.2509	0.065
Sept. ..	3,166	0.8868	74.8	0.421	0.2630	0.044
Oct. ...	3,326	0.9000	75.1	0.400	0.2100	0.039
Nov. ...	3,833	0.7700	72.7	0.330	0.2700	0.035
Dec. ...	3,274	0.7260	76.6	0.440	0.3000	0.044
1918						
Jan. ...	3,832	0.6640	73.0	0.353	0.2200	0.038

Average for period is:

Ore treated, tons	2,929
Assay, per ton.....	\$0.850
Extracted	0.642
Total cost	0.737
Loss per ton.....	0.095

Improvements are under way to increase mill capacity to its rated capacity of 8000 tons daily.

ARIZONA

AJO.—Little Ajo company has finished No. 1 drill-hole at depth of 1720 ft. Some low-grade ore was cut. Another hole is to be put down.

BISBEE.—Shattuck-Arizona and Denn-Arizona copper companies are to be consolidated at an early date.

CHLORIDE.—Arizona Ore Reduction Co. has started its new mill here, and is shipping lead concentrate.

CLIFTON.—Arizona Copper Co. has about restored its operations to normal; Shannon Copper Co. is not as well advanced;

nor is the Detroit Copper Co., at Morenci. These companies have had more to contend with in resumption than is generally realized.

COPPER BASIN.—Arizona Portland property has been formally taken over by the International Mines Syndicate. Three shifts of miners are to be employed, and a second power unit installed.

FLORENCE.—Grand Pacific has opened 7 ft. of up to 20% copper ore, and shipments are expected to commence April 1.

Queen Creek Copper Co.'s shaft is down 550 ft. in a 5-ft. vein of high-grade carbonate. Shaft will be sunk to 600 ft. Shipping is to commence in March.

Two feet of high-grade silver-copper-lead ore has been cut at \$30-ft. point in adit of Fortuna Consolidated Co. Another 30 ft. or so must be driven before main orebody is reached. Considerable water is flowing.

GLOBE.—High-grade copper ore has been opened in the Copper Vault mine, near the Cole-Goodwin mine. Shares owned by the New Dominion Mining Co. have been ordered deposited with the State Corporation Commission.

Arizona Commercial has opened good ore at 1500 ft. depth.

Iron Cap has cut 50 ft. of 6% ore on 1000-ft. level.

HAYDEN.—Labor dispute at smelter of A. S. & R. Co. here has been settled, men returning to work under old conditions, although some organized under the State Federation of Labor. Strikers demanded 50c. per day increase for all classes. Settlement was due directly to investigation made by Joseph F. Myers, Federal Mediator. He found that the smelting company is bound by an unprofitable contract made with Ray Consolidated company for a long term of years, and that it would ship Ray concentrate to its El Paso plant if expense at Hayden were materially increased. Such shipments have been made during the 10 days the Hayden furnaces were cold, serving as an effective object lesson to the strikers.

JEROME.—Demand of miners and mechanics for a flat raise of \$1 per day has been refused by the Federal Mediator, who thinks that living costs are not out of reason, but suggests that living conditions could be bettered by the companies.

Ore assaying 116 oz. silver, \$4.13 gold, and 5.75% copper has been found in new 2½-ft. vein on surface of Verde Hub. Diamond-drilling has been suspended owing to cold weather.

OUTMAN.—Gold Ore company has opened 16 ft. of \$15 ore on 650-ft. level. From above 500-ft. level this vein produced 3000 tons of \$14.50 ore that was treated at Gold Road mill in 1916. Reserves between 350 and 500 ft. are estimated from 15,000 to 20,000 tons. This plant has been leased by Gold Ore company, and will be ready to treat 50 tons daily by March 15. A. C. Werden is manager.

PHOENIX.—United Arizona Copper Mining & Smelting Co.'s property has been examined by A. H. Parker of this place. Mine is 32 miles south-east of Jerome, in the Copper Creek district of Yavapai county; also 35 miles south-east of the smelter at Humboldt. Country rock is granite or gneiss. Main shaft is down 660 ft. and is being sunk to 800 ft. Openings on the 150, 300, 460, and 620-ft. levels show considerable ore. At 620-ft. depth a large shoot of ore carrying copper, gold, silver, and molybdenite was opened. Near the centre of the lode is where molybdenite occurs. In the form of kidneys, ranging from 4 to 18 in. thick, the entire length of work done.

On the hanging wall some high-grade bornite glance and native copper shows in large quantities. Assays in copper are from 5 to 50% and 2 to 30% molybdenite. Gold and silver are sufficient to carry on all mining. The hanging wall of this vein is granite and the foot-wall porphyry. Property is equipped with modern hoist, air-compressor, and drills; also blacksmith-shop, tools, and buildings sufficient to care for employees.

RAY.—Ray Consolidated Copper Co. reports as follows for fourth quarter of 1917:

	Quarters			
	Fourth	Third	Second	First
Copper, pounds...	21,071,874	21,656,342	22,255,598	21,813,772
Profit	\$2,570,872	\$687,001	\$3,679,898	\$3,476,578
Dividends	1,577,179	1,892,614	1,577,179	1,577,179
Surplus	993,693	1,205,613*	2,102,719	1,899,399

*Deficit.

SENATOR.—Breed property, owned by Alex Ratcliff, has been purchased by the New Mexico Land & Copper Co. for \$15,000. Ore carries copper, gold, and silver.

TUCSON.—The four North Star claims in the Twin Buttes district have been sold to W. R. Ramsdell. Shaft on this property is down 110 ft. and is in 5% ore.

Contracts have been closed whereby the Douglas smelters are to take the full production of the Narragansett and Vulcan mines.

A strike of 12% copper and 42 oz. silver ore has been made at the Black Prince mine, 40 miles south of Tucson.

The 50 copper claims of the Mineral Hill Consolidated Copper Co., a Pittsburgh, Pennsylvania, corporation, are 20 miles from Tucson, on the road to Nogales. Development covers 10,000 ft. and shipments 60,000 tons of carbonate ore. Shipments ceased last July on account of smelter embargo. Sulphide ores are being developed. Main shaft is 500 ft. deep. Three other shafts are 200 to 300 ft. deep. At latter, ore-body is said to be 100 ft. wide. Copper content is 4%. Mine is equipped with four Fairbanks-Morse gasoline engines and three of the Western Gas Engine Co. The Ingersoll-Rand air-compressors of 670 cu. ft. is run by a 120-hp. Western Gas engine. A 75-hp. Fairbanks-Morse, type Y, 50-kw. generator has lately been installed for generating power to run a 235-gal. per minute Deane pump placed at 500-ft. level. These improvements were furnished by Harron, Rickard & McCone of San Francisco. Owing to restrictions caused by the War, only 40 men are employed, against 125 to 150 formerly. Fred G. Farish is manager.

ARKANSAS

YELLVILLE.—Manganese deposits near Batesville are to be developed by J. C. Shepherd, prominent in Arkansas zinc and lead mining.

CALIFORNIA

Most active field developments, coupled with an alarming decline in storage, are the outstanding features of the Californian oil industry for the year 1917, according to R. P. McLaughlin, of State Mining Bureau. Daily production amounted to only 90% of consumption, which was the greatest on record, being about 12,000 bbl. per day greater than during 1916, when current production supplied less than 90% of consumption. Increased consumption reflects the general industrial activity of the Pacific Coast. Under normal conditions such an increase would be welcomed, but the problem now confronting the oil industry is to supply other dependent industries with power from a continually diminishing store. The California State Mining Bureau is particularly charged under the law with supervising the method by which wells are drilled to prevent further damage to the oilfields by flooding with water. Other agencies have been recently organized by the Federal Government to supervise distribution and use of oil throughout the United States. Price of crude oil at the wells rose during the first half of 1917 from 73 to 95c. per barrel. Cost

of production—both labor and material—also rose during the year; and it yet remains to be seen whether the business of producing oil has been made more profitable than before. Contrary to common opinion, business of producing oil, which must not be confused with that of dealing in oil lands, has not in past years returned average profits commensurate with the risk involved. In view of unusual war conditions, a prophecy as to future prices would be hazardous. However, it would be difficult to advance reasons why prices should not be expected to fall. Considerable addition to the proved acreage was made by development of the Montebello field near Los Angeles, now showing from 800 to 1000 acres of proved land. Original discovery was made by the Standard Oil Co., and since then about a dozen other companies, both large and small, have entered the field. Several wells are flowing at the rate of over 1000 bbl. per day. Revised maps of the various oilfields are being prepared by the Mining Bureau. This work is being carried on as fast as other and more pressing work of the Oil Department permits. The past two years have witnessed many important additions to the various areas of proved oil land, and new maps should prove most useful. Maps will be in the form of blue-line prints, allowing for frequent revision and remarkably low selling price, which will merely cover the cost of blue printing.

Maps of the Santa Maria field have already been completed and may be obtained for 50c. each. Outlook for 1918 indicates unabated development activity in proved fields, and continued efforts to develop new oils. Undoubtedly there will be conditions causing a curtailment of consumption.

BARSTOW.—Strontianite deposits near this place are described by Adolph Knopf in Bulletin 660-I of the U. S. Geological Survey. The mineral occurs in the Mud hills, 10 miles

MAP SHOWING SITUATION OF STRONTIANITE DEPOSITS
NEAR BARSTOW

north, at an altitude of 3000 to 4000 ft. It consists of 37% strontium carbonate and 10.25% calcium carbonate. The high-grade mineral is crystallized in slender needles, and the lower grade resembles fine-grained dense-gray limestone. No great quantity is available at any one point, but the number of places at which strontianite has been found is surprisingly large. Deep mining will be impracticable on account of the loose unconsolidated condition of the clays in which the deposits are enclosed. Strontium is largely used in the beet-sugar industry.

COPPER CITY.—Arps Copper Co. will resume work early in March.

ENGELS.—Preliminary statement of Engels Copper Co. for 1917 shows gross earnings of \$1,307,123. Operations cost \$717,116 and depreciation plus mine depletion \$272,459, leaving \$317,548. Dividends were \$295,253. Balance from 1916 was

\$377,915, and that for 1918 is \$400,210. New mill, tram, air-compressors, shops, etc., cost \$552,240, and completion of Indian Valley railway \$179,000, a total of \$731,240. Officers are Henry Engels, president; F. Klamp, vice-president; E. E. Paxton, general manager; and L. A. Bell, secretary.

GORTSVILLE.—The Jack Clute property, near here, known as the Manzanita placer claim, recently leased by A. W. Boslough and Lewis G. Gieve of Ashland, Oregon, is being equipped with a 16-hp. gasoline engine and a 6-hp. engine and hoist. This is a drift mine and an old producer.

HORN BROOK.—Heavy rains for the past month have been a boon to placer mining throughout Siskiyou but has made roads impassable.

The Rancheria Mining Co.'s mines near Hornbrook are being operated by 12 men. Besides new equipment in the mill, an expensive flume has been completed to carry the water over the head of Wagner ditch to pump its tailing so as not to interfere with the Wagner ditch holdings.

The Hazel gold mine and mill near here resumed last week after being idle for over four years. It was re-equipped at large expense. Two shifts are operating in the mine and mill. A large body of rich ore is being opened.

INGOR.—Afterthought Copper Co. resumed work and the flotation plant will start about March 8. Thirty men are employed, and mine is in good physical condition.

KENNETT.—Friday-Lowden adit of Mammoth Copper Co. has cut main orebody.

Shasta King mine, under bond to U. S. Smelting Co. from Trinity Copper Co., employs 70 men, and ships 200 tons of ore daily to smelter at Kennett.

MARIPOSA.—Mountain King company is to deepen its 1400-ft. shaft to 2000 ft., and do extensive exploration. The mill is crushing good ore steadily.

Mount Gaines mine has a 100-hp. electric hoist installed, and mill overhauled.

At Ruth Pierce mine 35 men are employed, the mill crushing rich ore. High-grading is reported as prevalent.

MANONIC.—Tanawah property of M. A. McClain in Mono county has been sold to C. H. Ernst of Pacific Grove, California. Deal includes 10-stamp mill, cyanide plant, dwellings, water-rights, etc. Past gold output is said to total \$1,000,000, but litigation kept mine closed for several years. Tanawah and United groups are to be merged by Colorado and Illinois people.

The Silverado continues shipments of high-grade ore.

PORTOLA.—Walker copper mine is yielding 85 tons of 6% ore daily. Shaft started from adit-level is 400 ft. deep, and ore-shoot is over 1000 ft. long.

RANDSBURG.—Miners and Claim-Owners' Convention held recently was a success, and another gathering is scheduled for April 15, 16, and 17. A protest was made against an attempt to extend boundaries of Sequoia National Park, as this would prevent development of mineral-bearing land adjoining the Park. California Blue Sky law was deprecated and deplored because of its alleged handicap to legitimate mining industries and driving capital from the State to seek investment elsewhere. Permanent officers of the Rand District Mining Association were elected as follows: president, H. D. Osdick; secretary, H. B. Watson; and treasurer, W. McLean.

REDDING.—U. S. Smelting, Refining & Mining Co. has shut-down its Sutro mine, near the Mammoth, laying off 30 men. This action was taken because the Shasta King mine, which is under option from the Trinity Copper Co., has doubled its daily output of ore. The company was receiving more ore at its smelter at Kennett than could be treated, so some of its properties had to be shut-down. The smelter has a daily capacity of 800 tons.

Louis Gardella's No. 2 dredge on Clear creek, three miles below Redding, will be ready to start about March 15.

C. H. Mitchell is prospecting the Kleineberg ranch, two miles below Redding, with a Keystone drill to determine whether it will pay to dredge the ground. Ranch is at mouth of Oregon gulch, famous placer diggings in early days.

Ten-stamp mill on Texas mine in Old Diggings was burned in order to get at the old iron and machinery, which had been sold for junk. The mill was in ruins, being idle for nearly 20 years. There is now not a single stamp-mill at Old Diggings; once there were four.

SAN BERNARDINO.—Thirty-five specialists of the U. S. Geological Survey are examining nitrate deposits in Death Valley, under supervision of Hoyt S. Gale and G. R. Mansfield. The deposits occur within an area of five miles near Saratoga Springs, on the Tonopah & Tidewater railroad. The area was superficially prospected about 12 years ago by the Pacific Nitrates Co., when Barstow was the nearest railroad point. At that time considerable low-grade material was found, but the low price prevailing discouraged further work.

Ore deposit containing radium has been discovered by M. E. Cox and others of Los Angeles in the Black Mountain district, 32 miles east of Victorville. Lode near top of the mountain is 35 ft. wide, and numerous smaller veins outcrop on the slope. A. N. Milner has reported favorably on the property, and preparations are being made for extensive work.

COLORADO

BLACKHAWK.—Red Cross M. M. & R. Co. has secured lease on Sub-Treasury mine. A mill will probably be erected by owner, the Coloma Mining Company.

BRECKENRIDGE.—Governor silver-gold mine, 7 miles south, is to be re-opened.

CRIPPLE CREEK.—Gold output of district in February was \$869,582 from 82,284 tons of ore treated.

PUEBLO.—Colorado Fuel & Iron Co. reports for last quarter of 1917 gross revenue was \$10,297,609, against \$9,157,817, a year ago. Net earnings were \$2,033,971, and net surplus \$1,540,816.

SILVERTON.—Ore shipments from district during February totaled 40 carloads.

IDAHO

KETCHUM.—Stewart-Faucett syndicate is consolidating properties in Little Smoky district of Blaine county, southern Idaho. Carrie Leonard silver-lead mine, with past yield of \$500,000, is included in the 18 claims. A 100-ton mill may be erected. District is 30 miles from Ketchum.

Silver Star property in Little Smoky district has been purchased by Rodsford and others of California. Ore carries silver, and low prices coupled with poor transportation facilities led to suspension of work.

MULLEN.—Men employed in this district number 1000, largely increased by recent resumption of work at Morning mine of Federal company.

Mayflower Mining & Development Co. is to resume work at its mine after 5 years suspension. An assessment has been levied. J. H. Foss is president.

PINE CREEK DISTRICT.—Ore shipments are impossible at present, and the date of resumption is unknown. Roads are in bad condition, and work on the new railway is indefinite. The district is dull as a result. Before winter the Douglas employed 80 men; now it has only two. The Marmion claim of this company is opening well, a recent development showing ore assaying 51% lead, 20.6% zinc, and 23.8 oz. silver per ton.

KANSAS

BAXTER.—Production of this and Treece district last week was 1173 tons blende and 519 tons lead, valued at \$107,973.

Aksarben Mining Co. is to erect a mill on a lease of the Cooper land, near this place. John Voohees of Anita, Iowa, is president.

TRICE.—Commonwealth Lead & Zinc Co. is to erect a mill

near this place. Drills have opened a good deposit at 260-ft. depth.

De Armond Mining Co.'s 300-ton mill is ready for treatment of ore opened at 160 ft. M. M. De Armond is manager.

MICHIGAN

Houghton.—Wolverine produced 350,957 lb. copper in January. Ore averaged 13.35 lb. per ton, lowest on record.

Mohawk produced 984,343 lb., ore yielding 20.18 lb. per ton. Ahmeek is treating 4600 tons daily of 20-lb. ore.

Victoria Copper Mining Co.'s profit in 1917 was \$97,419, compared with \$153,905 in 1916. Production was 1,612,640 lb.

MISSOURI

Galena.—Wayland Mining Co. has opened 25% blende at depth of 234 ft. Ore is 50 ft. thick. Production has been coming from 90-ft. depth. L. H. Phillips is manager. This deep drilling is likely to start other similar work in the district.

Joplin.—Production of Kansas-Oklahoma-Missouri region last week was 6352 tons blende, 80 tons calamine, and 1775 tons lead, averaging \$54, \$33, and \$83 per ton, respectively. Total value was \$496,544, making \$3,618,885 for 8 weeks.

No. 2 mill of the Waco Mining Co., in the Waco-Lawton district commenced work two weeks ago. It has a capacity of 450 tons in 10 hours. Equipment includes an 18-in. breaker, one set of 42-in. rolls, two sets of 36-in. return rolls, and one set of 24-in. chat rolls. There is a six-cell rougher, with cells 36 by 48 inches in size, and a seven-cell cleaner-jig, with cells 34 by 42. The centre-drive system has been installed in the mill. There is an independent feed elevator, and independent tailing elevator for the sludge department, which holds 10 Wilfley tables and two slime-tables. Sand-tanks are used at present, but Dorr equipment probably will be added later. The mill proper is operated by a 14 by 42-in. Corliss steam engine, capacity being about 200 hp. Another Corliss engine, 11 by 30, furnishes power for the sludge department. A 600-cu. ft. Ingersoll-Rand cross-compound compressor is being installed, there being a smaller one already in use. The nature of the ground, however, does not call for great compressor capacity. The dump-pile at this mine is equal in size to any of the Oklahoma bonanza properties. Exceptionally rich 'dirt' is being taken out of No. 2 shaft at a depth of 122 ft. Shafts No. 1 and 3 are being sunk deeper. No. 1, which now is down 195 ft., will be put down to the 300-ft. level if this seems practical. No. 3 is now down about 100 ft. Within the past week another rich strike has been made by the company about 600 ft. from the mill, to the north-west, and another shaft will probably be sunk here. Surface tramping will be used for all the field shafts, mules being used at first and probably gasoline locomotives later if warranted. P. B. Butler is manager.

Klondike.—On Aylar land, I. L. Burch and S. S. Cummings have put down six drill-holes, which show rich lead and zinc ore from 105 to 140-ft. depth. A shaft is to be sunk, followed by erection of a mill.

MONTANA

Bannack.—C. W. Stalling, leasing the Hendricks gold mine here, has developed a fair quantity of \$10 ore, and may erect a 5-stamp mill.

Dunkleberg.—In Bulletin 660-G, of the U. S. Geological Survey, J. T. Pardee describes this mining district of Granite county. This place is 50 miles north-west of Butte. Intermittent work during 30 years has yielded \$200,000 in silver and lead. Lodes are generally narrow, and are simple quartz veins in fissures that follow inclined bedding planes, or cut across the sedimentary rocks and diorite sills. Silver-bearing galena and lead carbonate are the valuable minerals, although zinc blende is commonly present. The Wasa is the largest

mine. Others are the Sunset, Pearl, Summit, Forest Rose, Hatta, and Jackson.

Butte.—Lexington zinc mine of Anaconda company resumed work last week, after being closed from May 1917. Normal ore output is up to 350 tons daily.

Butte & Superior Mining Co. reports as follows for fourth quarter of 1917:

	Quarters			
	Fourth	Third	Second	First
Ore milled tons..	126,175	60,106	126,737	148,935
Zinc, per cent....	15.76	15.14	15.304	15.491
Silver, ounces....	6.02	5.85	5.5830	5.7730
Zinc concentrate, pounds	37,741,179	17,396,952	75,340,000	85,042,000
Zinc, per cent....	48.77	47.55	46.509	47.131
Silver, ounces....	18.34	18.16	17.676	17.256
Mill recovery, per cent	94.84	95.62	90.329	86.821
Mining cost per ton	\$5.73	\$5.86	\$4.7596	\$4.6839
Milling cost per ton	2.48	2.52	2.4001	2.6496
Total cost per ton	\$8.22	\$8.38	\$7.1597	\$7.3385
Average price used in estimating returns for spelter was 74c. per pound.				
Total income....	\$1,749,558	\$04,643	\$2,040,930	\$2,275,619
Profit	\$64,017	\$5,320	\$1,003,236	\$1,061,020

MAP SHOWING SITUATION OF DUNKLEBERG DISTRICT, MONTANA

Helena.—Helena mine in Grass Valley district has sent to smelter 45 carloads of silver-lead ore since the property was taken over by the Helena Mining Bureau a little over a year ago. Ore was stoped from above the 300-ft. level and is shipped direct to the smelter without sorting. Vein is over 2 ft. wide, and in places 10 ft. Negotiations are pending that may end in a sale of the mine. Spokane interests and local people have made offers.

One carload of gold-silver ore from the Gould placer has been shipped to the smelter. The ore is from a blind vein found while excavating for a reservoir.

Economy mine in Mitchell gulch has installed an electric pump. Ore is being blocked out for milling. Anson & Co. have opened a 25-ft. vein in Scratch Gravel hills. Ore, silver-gold-lead, is of milling grade, and some is being sorted for shipment to smelter.

Cruse Developing Co. is making regular shipments from the new shoot uncovered at the 640-ft. level.

B and G shaft of the Mountain States Mining Co. has been

re-timbered to the 50-ft. level and machinery has been ordered. When the new hoist and pumps are in place the shaft and levels are to be unwatered to the 250-ft. level, the lowest worked in the past.

A new strike of lead ore on 200-ft. level of Rock Rose mine assays \$40 per ton.

Peerless Queen company is cross-cutting from the hanging to the foot-wall on the 300-ft. level.

NEVADA

BULLION.—A smelter is to be erected at this place in Elko county by William Patterson and J. D. McFarlane. F. G. Buick is engineer. It is said that there is enough ore in the district to keep the plant operating.

ELY.—Consolidated Coppermines company produced 1,128,925 lb. copper in January. In December, 24,000 tons of ore was treated.

Nevada Consolidated Copper Co. reports as follows for last quarter of 1917, compared with previous periods:

	Quarters			
	Fourth	Third	Second	First
Copper, pounds...	22,153,158	20,217,673	20,817,356	18,852,321
Profit	\$1,822,165	\$1,988,323	\$3,546,741	\$3,238,474
Dividends	1,999,457	2,299,375	1,999,457	1,999,457
Depreciation, etc.	249,061	233,145	236,851	216,557
Surplus or deficit.	-426,353	-544,196	+1,311,542	+1,022,459
Cost of producing copper	was 11.91c. per pound.			

GOLDFIELD.—Great Bend mine shows in slope 7 ft. of \$55 to \$330 ore. On 160-ft. level is \$45 ore.

Winze below 400-ft. level of Red Hill Florence is down 35 ft. in rich ore. A drift has been started at this depth. Ore is to be shipped soon.

TONOPAH.—Standard Oil Co. is constructing a spur from Scranton, on Tonopah & Tidewater railroad, to an extensive deposit of clay near Fairbanks Springs, in Amargosa valley. Property has been held under patent for 10 years. The clay is an excellent substitute for fuller's earth. Activity of company in this field caused oil excitement in Tonopah, Goldfield, and Pioneer, hundreds of locations being made in belief that the company had discovered oil.

Tonopah Divide Mining Co., in the Gold Mountain district, cut a vein on 270-ft. level at 160 ft.; it was 24 ft. wide, carrying gold, silver, and molybdenum. Last mineral occurs as wulfenite. Same condition exists on the lower level, cross-cut having penetrated 20 ft. without reaching the other wall.

VIRGINIA CITY.—Under management of Whitman Symmes, development of the North End mines on the Comstock is proceeding on the largest scale in 20 years. Old workings are being repaired, and good ore has been exposed at several points in the deeper levels. Orebody recently discovered on the 2300-ft. level of the Union Con. has been opened for 130 ft. at a point 60 ft. below the 2400-ft. level, and shows greater strength there than at 2300 ft. Output is approximately \$60,000 per month, and No. 2 dividend, at the rate of 5c. per share, will be paid March 1. Sufficient ore is stated to be exposed to insure numerous dividends, with a possibility of extra profits. Exploration to find the orebody on levels below 2400 ft. and above 2300 ft. are being made.

Sampling of veins at 2000 and 2100 ft. of the Ophir has been made, and preparations are in progress for extensive work at both points. Considerable \$18 ore has been sent lately to the Mexican mill.

Driving north is proceeding from the 2500-ft. station of the Sierra Nevada on a promising shoot, while work is expected to intersect the main vein.

From the 2300 and 2900-ft. levels of the Mexican new work has started, with good ore exposed.

In the Con. Virginia principal attention is being devoted to the 2700-ft. level, where ore conditions are fair.

Installation of new equipment is progressing at the mill of

the Jacket Con. Good ore continues to be drawn from the adit workings on Gold hill, and the mill is running at about 50% capacity.

YERINGTON.—Nevada-Douglas reports net profit of \$22,493 from mining operations in January and \$10,000 from Nevada Copper Belt railroad. Daily ore shipments to the Mason Valley smelter are now 250 tons, against 100 tons in December.

NEW MEXICO

SANTA RITA.—Chino Copper Co. reports as follows for last quarter of 1917:

	Quarters			
	Fourth	Third	Second	First
Copper, pounds...	20,266,715	21,887,390	20,546,593	19,225,111
Profit	\$2,224,847	\$963,409	\$3,725,661	\$2,912,698
Dividends	1,739,960	2,522,942	2,174,950	2,174,950
Surplus	542,207	1,478,417*	1,643,372	\$17,121

*Deficit.

OKLAHOMA

DOUTHAT.—The Carnegie Milling Co. has bought the National Zinc & Lead Co.'s 300-ton mill at Webb City, Missouri, and is moving it to its lease near Douthat. P. L. Bucy of Bartlesville is president.

PICHER.—Production of zinc-lead region last week was 3836 tons blende and 850 tons lead, valued at \$282,999.

QUAPAW.—Spelter Mining Co. plans erection of mill on a lease of Abrams land. J. J. Gurlach is president.

Miami-Ada Mining Co. in drilling passed through 42 ft. of ore, beginning at 190-ft. depth. J. M. Ramsay is president.

OREGON

GALICE.—Gold Bar placer mines on Rogue river, below Galice, have been sold to Hayes Temple, Gust Fisher, and Alfred Eubanks, of Seattle, Washington. New owners are operating with three giants and a steam-shovel.

GOLD HILL.—J. W. Davies and associates, lessees of the Cheney, Simmons, Haff, and Ray gold claims, 3 miles north, have opened rich ore at 400-ft. depth, enough to repay development and purchase-price—\$100,000. The new shoot was found at end of a 900-ft. drift. Three years ago, Ray and Haff, lessees, discovered scheelite in the gold ore, the vein averaging 2% tungstic acid. Most work on the group is in the Cheney and Simmons claims, generally known as the Sylvanite mines, developed by the Sylvanite Mining Co. The lode contains quartz with pyrite; carrying gold and silver valued at \$3 to \$5 per ton. High-grade ore occurs in boulders, at a depth of 80 to 100 ft. Sulphide ore begins to appear at 160 ft., and the vein is 5 ft. wide at 225-ft. depth. The hanging wall is slate, and foot-wall limestone. Greatest depth attained on this lode is 600 ft., where it is 25 ft. wide.

UTAH

BINGHAM.—Utah Copper Co. reports as follows for last quarter of 1917:

	Quarters			
	Fourth	Third	Second	First
Copper, pounds...	50,802,793	54,762,544	56,403,465	42,866,316
Operating profit.	\$8,117,812	\$1,030,221	\$8,898,628	\$5,775,601
Other income	222,471	178,428	189,413	120,213
Nevada Cons. dividends	1,000,500	1,150,575	1,000,500	1,000,500
Bingham & Garfield dividends.		475,000	475,000	350,000

Total available...	\$9,340,784	\$2,834,225	\$10,563,541	\$7,246,318
Dividends	5,685,715	6,497,960	5,685,715	5,685,715
Surplus	3,655,069	3,666,734*	4,877,826	1,560,602

*Deficit.

ALTA.—As the Red Bell Mining Co. wishes to haul ore down Big Cottonwood canyon by horse-drawn vehicles the City Com-

mission of Salt Lake City has refused permission on the grounds that the city's water supply would be contaminated. The company is very vexed at being treated thus.

AMERICAN FORK.—Pacific Mining Co. pays one cent per share on March 15. This is No. 3 dividend, equal to \$4000. Mill is treating 150 tons daily.

EUREKA.—Profit of Eagle & Blue Bell Mining Co. in 1917 was \$477,229 net, against \$154,776 in 1916, \$143,345 in 1915, and \$121,536 in 1914.

Eureka Lily's first car of ore averaged 12% copper, 30 oz. silver, and a little gold, equal to \$64.50 per ton. This came from depth of 1400 feet.

Tintic Standard has installed a 35,000-cu. ft. fan on its 1200-ft. level to improve ventilation. Shipments last week were 13 carloads.

Tintic Milling Co. is having difficulty in operating at capacity on account of ore-dumps being frozen. T. P. Holt is superintendent.

WASHINGTON

CHEWELAH.—Profit of United Copper M. Co. in 1917 was \$113,000, equal to 11.3c. per share. Eleven monthly dividends of 1c. each absorbed \$110,000. Ore and concentrate sales totaled \$312,000, from 28,000 tons treated. Reserves increased by 116,000 tons. Shut-down of Trail smelter reduced output and dividends.

REPUBLIC.—Knob Hill Mining Co. during 1917 reported revenue from ore sold \$102,143 net. Wages absorbed \$46,800, and dividends \$34,784. The shoot opened on the new level averages \$16 gold per ton.

San Poil mine is to be explored at depth by diamond-drill, the Consolidated Mining & Smelting Co. of Canada to do this at 200, 400, and 700 ft. below the main adit.

CANADA

BRITISH COLUMBIA

GRAND FORKS.—Granby Consolidated's copper output in January was 3,383,496 lb. from Anyox and 825,897 lb. from Grand Forks, a total 4,209,393 lb., compared with 2,946,476 lb. a year ago, and 4,468,388 lb. in December.

SILVERTON.—Profit of Standard Silver-Lead company in December was \$24,174, against \$10,917 in November. Surplus at end of 1917 was \$202,801. Zinc sales realized \$57,382.

TRAIL.—New treatment charges by Consolidated Mine & Smelting Co. of Canada are giving operators in the Province considerable concern. They provide for a payment on ore containing not more than 4% zinc, 95% of the silver, and 90% of lead. With each increase of 1% zinc company will reduce the amount of silver it will pay for by $\frac{1}{2}$ of 1%, and it will reduce the amount of lead it will pay for by 1%. Ore containing more than 25% zinc will not be accepted. If ore contains more than 0.05 oz. gold, 95% of the gold will be paid for at \$20 per oz. An additional charge of 50c. per unit per dry ton of material, but not to exceed \$4 per ton, will be made for sulphur in ore. A minimum deduction of $\frac{1}{2}$ of 1% will be made for moisture. Flotation concentrates will be charged \$1 extra per dry ton. Charges for smelting will be increased or decreased 25c. per ton whenever the cost of coke increases or decreases. The charges will be increased or decreased $\frac{1}{2}$ c. per ton for each 1c. increase or decrease of change per shift in the wages paid.

A. I. M. E.

The next meeting of the San Francisco section is called for March 12, when W. W. Bradley, of the State Mining Bureau, will speak on new developments in the metallurgy of quicksilver. L. H. Duschak, of the U. S. Bureau of Mines, will lead the discussion. The meeting will be at the Engineers Club, 57 Post street, at 7:30, preceded by an informal dinner (\$1) at 6:30.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

E. GYBRON SPILSBURY is in Cuba.

A. F. BENNETT is at Tucson, Arizona.

HENRY E. WOOD is at La Jolla, California.

E. V. DAVELER has returned to Thane, Alaska.

JAMES A. McDONALD, of Tucson, is at the Palace hotel.

E. P. MATHEWSON, accompanied by E. F. W. SALISBURY, is here.

ROBERT A. KINZIE has returned from Sierra county, California.

F. W. DRAPER has returned from Russia to Allston, Massachusetts.

A. E. CARLTON, of Denver and Cripple Creek, was here during the week.

T. B. HASKINS is in the 158th Infantry at Camp Kearny, California.

D'ARCY WEATHERBE sailed from New York for Liverpool on February 26.

WILLIAM MACDONALD is again with the Olympic Mines Co., at Omco, Nevada.

LEWIS N. BAILEY is in the 4th U. S. Engineers at Camp Greene, North Carolina.

K. D. KOLASNIKOFF, of the Kyshtim mine, is expected in San Francisco from Siberia.

E. H. CLAUSEN has returned to San Francisco from the Colorado mine, Philippine Islands.

IRVING S. McREAVY has been appointed manager of the Temiskaming mine at Cobalt, Ontario.

ALFRED TELLAM has arrived from Yokohama, on his way from the Ridder mines, in the Altai, Siberia.

JOHN BAILLOT is here to be present at the hearing of the flotation case before the Court of Appeals.

D. M. FOLSON has been appointed Federal Oil Director for the Pacific Coast, acting under Mark L. Requa.

ANDREW M. TWEEDY, resident manager for the South American Mines Co., at Zaruma, in Ecuador, is expected here.

L. O. KELLOGG, superintendent, is acting as manager of the Zaruma gold mine, in Ecuador, in the absence of the manager.

J. PARKE CHANNING has been chosen president of the Engineering Council, the organization of national technical societies.

MILF S. KETCHUM, of the University of Colorado, is in West Virginia directing construction, under D. C. JACKLING, of the Government smokeless-powder plant.

ROBERT E. DYE, formerly superintendent of the Buffalo mill at Cobalt, is manager of the Teck-Hughes mine at Kirkland Lake, Ontario, succeeding W. LEDYARD.

Obituary

A. H. PURDUE, State Geologist for Tennessee, died at Nashville on December 12, 1917, as a result of an operation. He was a graduate of Stanford University, was 56 years old, and left a wife and two sons. His work in Tennessee was valuable.

HENRY KENOE, mining engineer, died at Los Angeles on February 6. He had been actively engaged in mining for 30 years, in the early 'eighties in Arizona and northern Sonora, later in the Black Hills, Cripple Creek, and Rossland. As examining engineer for different American and Canadian companies he traveled extensively in Alaska, western Canada, Mexico, and Central America. For the past two years he has been in Arizona and southern California, leaving Spokane, Washington, in 1915. He was 55 years old.

Tin average for February is not available, but according to position, Banca metal is quoted at about 72 to 73½¢ and Chinese 67½ to 70 cents.

Eastern Metal Market

New York, February 27.

All markets were closed in New York on Friday, Washington's birthday. Generally the demand for all metals is light. Copper is featureless with conditions unchanged. Tin is quiet with spot metal nominal. Lead is a little more active and higher. Zinc is extremely dull, and is being shaded. Antimony is quiet and unchanged.

Steel-makers will confer in New York on March 1 preparatory to a meeting with Government representatives to consider the prices that are to prevail after April 1, the time set for a possible revision of the present fixed schedules. They ask for stabilized prices over a period of six to nine months after months of constant annoyances and steadily advancing costs. Iron and steel-works operations have steadily improved in the past week. The U. S. Steel Corporation now has 75% of blast-furnace capacity operating, as well as 85% of active ingot capacity and 80 to 85% in rolling-mills. Other companies have not fared as well.

COPPER

There is little interest in the copper market, and news of the usual market nature is impossible, with sales and distribution so tightly controlled by the Government and the Copper Producers' Committee. It is the same story each week—large quantities being absorbed by the Government and the Allies at the Government fixed price of 23.50c. per lb., with regular domestic consumers supplied at the same price if there is any metal available after war-needs are taken care of. It is claimed in some quarters that costs are advancing at Eastern refineries possibly so as to restrict earnings and perhaps the output also. Laborers in the refineries are constantly leaving to take more lucrative positions in shipbuilding plants and other Government work. Refinery workers are now getting 38c. per hour as compared with a normal wage of 23.50c. per hour. A refiner who discussed the conditions said, during the last week that, if a further advance in wages were to be made, the profit on the smelting of copper, lead, and zinc at Eastern works would practically disappear. It is likely that these considerations will come up when the price revision as of June 1 is taken up, and it will be used to argue for at least a 25 or 27c. price for copper. The copper exports for January, of 48,637 tons, compare with a monthly export of 40,311 tons in 1917—a year when the total was phenomenal. The refinery output of the country is estimated at 2,780,000,000 lb. per year, as compared with 1,778,000,000 lb. annually before the War.

Copper sheets, hot rolled, are quoted at 30 to 31.50c. per lb., at the mill, with cold rolled about 1c. per lb. higher. Copper wire is held at 26 to 27c. per lb., at the mill, for carloads.

TIN

Business is confined to off-grade tin and to future positions, there being very little spot tin available. The past week has been a quiet one, with no news-feature of interest. In off-grades a little business is reported as having been done, but the total sales did not involve large quantities. It is somewhat surprising to witness the extent to which consumers are readily absorbing off-grade material, such as Chinese tin. Not long ago they could not be influenced to consider it. As to Straits tin—there is nothing doing—even in futures. The policy is simply to look on, to wait, and to do nothing. The London market has advanced again to £319 10s. per ton, as against £316 a week ago for spot Straits. Arrivals have been fairly good, the total for the month, including yesterday, having been 1040 tons. It is estimated that there are 4900 tons afloat.

LEAD

The news feature of interest is another advance in the price of lead by the American Smelting & Refining Co. Yesterday this company raised its quotation ¼c. per lb. to 7.25c., New York, and this is the second advance in the last three weeks. The outside market also kept pace, and is quoted at 7.25c., New York, or 7.10c., St. Louis. More interest has been displayed in the market in the last week, and the demand is reported as picking up slowly. The strength of the market is due largely to the fact that transportation difficulties continue to interfere with the flow of metal to the market, though some here state that receipts from railroads have been better recently than in many weeks. That the price will go any higher, however, is not likely, according to responsible opinion.

ZINC

Outside of the large quantities of grade A and high-grade zinc which the Government and the Allies are buying each week or month, the market is lifeless and without interest. Production is reported as still being curtailed. Prime Western, for early delivery, is held at 7.75c., St. Louis, or 8c., New York, but this is being shaded slightly to 7.70c., St. Louis, on small and carload lots. Bids are being taken by the Government on 500 tons of grade C zinc, which is nearly the same as prime Western in quality, but otherwise inquiry is of no importance. Canada is inquiring for prompt and March shipments. Receipts of metal from the West are much better, due to the milder weather of the past two or three weeks.

ANTIMONY

The Government last week bought 130,000 lb. of antimony from the lowest bidder at 13.50c., New York, duty paid. This is the present quotation for prompt and March delivery but the market is very quiet.

ALUMINUM

Some regard the market for No. 1 virgin metal, 98 to 99% pure, as stronger at 37 to 39c., New York, for prompt and March delivery. This quotation is nominal, however, and has not been established by any sales.

ORES

Tungsten: A fair business for future delivery is reported in the past week. This refers largely to imports from South America and the Far East. Chinese ore from Hongkong can now be shipped to the United States if permitted by the British government. A Chicago house was offering Chinese tungsten ore in the East recently. Prices range from \$20 to \$26 per unit in 60% concentrates, according to quality. Ferro-tungsten is a little lower at \$2.25 to \$2.35 per lb. of contained tungsten.

Molybdenum: This is unchanged at \$2.15 per lb. of MoS₃, with business confined to small quantities and the demand light.

Manganese: About 2000 tons of high-grade ore has been received from a South American country, which has not been a source of such ore previously. It contains 51% manganese, 0.007% phosphorus, 8.5% silica, and under 3% iron. More is under negotiation and on the way. A large steel company is converting it into ferro-manganese. Prices for high-grade ore still range from \$1 to \$1.30 per unit, tidewater or mine.

METAL PRICES in London at end of January were £125 per ton for electro copper, £29 10s. per ton for lead, £299 per ton for tin, and £54 per ton for zinc. These are official quotations.

Silver Market in 1917

The 'Annual Bullion Letter' of Samuel Montagu & Co. of London has come to hand, and the following notes on silver are abstracted therefrom:

Factors influencing prices may be summarized as under:

Month	London pence	New York cents	Factor
January	36.682	75.630	{ Indian Mint as buyer most of the year
February	37.742	77.585	
March	36.423	73.861	{ Free China selling. Indian Bazaars 'bear' silver.
April	36.963	73.875	
May	37.939	74.745	{ United States government buys for coinage.
June	39.065	76.971	
July	40.110	79.010	{ Indian bears cover, and Indian government took power to acquire private imports.
August	43.418	85.407	
September	50.920	100.740	{ Entry of China into War, and loan to its Government.
October	44.324	87.332	
November	43.584	85.891	{ Highest price reached since 1878.
December	43.067	85.960	
Av. month..	40.853	81.417	{ Prohibition of export to certain neutral countries, save under license.
			{ Foreign business restricted by war conditions.
			{ Fair English trade demand.

Exports and Imports of Gold and Silver in the United States during Four Years

Early in 1917 the stability of the market was remarkable, creating confidence for the future. Subject to a slight upward inclination, prices remained about the opening quotation for the succeeding five months. By June, the market everywhere was well cleaned out of supplies, and so sensitive that it was ripe for an advance in price. In this month and July the trend was steadily upward, excepting a slight reaction on July 27. Then a remarkable advance commenced, which without a single set-back, carried the price on September 21 to 55 pence, or £1.085 per ounce, the highest since March 1878. The main factor in this extraordinary movement was the attempt of China to replace some of its currency which had been shipped abroad in large quantities during the year. China's entry into the War made the demand imperious. A spectacular fall followed this rise, due to a rumor that the United States government might dispose of part of its silver holdings, and the demand for China ceased. On October 30 there was a record drop of 3 pence, or 6 cents, down to 43 pence, or 86 cents, about where prices remained for some time. During the first two months of 1918, save an upward movement in the middle of January, there has been little change.

The Royal Mint's operations in silver coin in 1917 were £4,514,017, compared with £10,362,026 in 1916, £7,404,087 in 1915, and £1,247,720 in 1914. Withdrawals of coins during these periods were £191,695, £915,545, £145,457, and £602,045, respectively.

Gold and Silver Movements in 1917

The following statistics are from the 'Monthly Summary' published by the Department of Commerce, Washington, D. C., and the above chart was prepared from the figures given:

SILVER EXPORTS TO					
Year	Total	China	England	Hongkong	India
1915	\$53,598,884	\$121,663	\$38,907,765	\$8,250,155
1916	70,595,884	6,273,081	53,431,212	3,197,341	\$2,884,467
1917	84,130,876	7,944,142*	25,725,720*	8,612,757*	17,133,899*

*10 months.

These figures show why England dominates the silver market, also the new movement of metal across the Pacific instead of the Atlantic.

Monthly Average Price of Silver for Four Years.

SILVER IMPORTS FROM

Year	Total	Canada	Mexico	Peru
1915	\$34,483,854	\$6,701,583	\$20,487,708	\$4,544,124
1916	32,263,289	5,817,802	15,629,005	7,316,390
1917	53,340,832	5,526,042*	21,144,772*	5,817,761*

*10 months.

Most of the imports came in ore or in base bullion.

GOLD EXPORTS TO

Year	Total	Canada	China	Cuba	Japan	Spain	South America
1915	\$31,425,918	\$11,587,395	\$300,199	\$14,026,380	\$250,000	\$50,000	\$2,397,453
1916	155,792,927	8,611,424	5,207,343	28,659,250	26,131,826	16,988,383	37,597,178
1917	371,883,884	10,308,082*	15,409,786*	155,467,726*	102,066,789*	49,541,870*

*10 months.

The increase to Japan and Spain is remarkable.

GOLD IMPORTS FROM

Year	Total	Australia	England	Canada	France	South America	West Indies
1915	\$451,954,590	\$34,019,181	\$109,174,650	\$218,910,742	\$11,519,880	\$15,940,752	\$16,483,604
1916	685,990,234	15,519,050	57,131,507	579,337,169	38,829	9,847,141	9,917,421
1917	537,854,374	12,166,333*	6,332*	498,965,213*	23,845*	6,415,998*	144,244*

*10 months.

Canada has handled over \$1,000,000,000 in gold for the Bank of England and Imperial Government since the War began.

Company Reports

PORTLAND GOLD MINING CO.

PROPERTY: mines and mills at Cripple Creek and mill at Colorado Springs.

OPERATING OFFICIALS: F. L. Smale, manager at mines; G. M. Taylor, manager at mills.

FINANCIAL STATEMENT: revenue in 1917 from bullion was \$2,504,951, plus \$22,569 from other sources. Costs totaled \$1,864,266, leaving profit of \$663,254. Balance at beginning of year was \$341,753, and at end \$278,383. Current assets are \$595,421, and liabilities, \$13,477.

DIVIDEND: paid in 1917 amounted to \$360,000, making \$10,957,080 to date.

DEVELOPMENT: amounted to 12,507 ft., making 323,357 ft. to date. No. 2 shaft was sunk 100 ft., and No. 20 level opened. Ore here is equal in value to the three levels above. Shoots 717 ft. long have been opened, with limits not reached. The Roosevelt drainage-tunnel reached Portland boundary, and a branch is being driven to No. 2 shaft. A small pumping-plant will be installed at this point when connections are made, making possible opening of several levels below.

PRODUCTION in 1917 was as under:

Company ore shipped to Colorado	Tons	Value	Total
Springs plant	56,272	\$22,244	\$1,251,723
Lessees' ore shipped to Colorado			
Springs plant	19,270	18,970	365,683
No. 1 reject to Victor mill.....	27,721	2,247	62,289
No. 2 reject to Victor mill.....	82,141	2,247	184,571
Ore from stopes to Victor mill.....	12,564	2,247	28,231
Ore from development to Victor mill	11,837	2,274	26,598
No. 2 dump ore to Victor mill.....	88,569	2,247	199,015
No. 1 reject to Independence mill.....	21,327	1,762	37,578
No. 1 dump ore to Independence mill	215,588	1,762	379,866

Totals and average.....535,289 \$4,737 \$2,535,554
Production to end of 1917 was \$46,580,602, contained in 3,372,605 tons of ore.

By April 1918 management expects to be treating 60,000 tons per month in its three plants. Surface dumps contain large quantities of ore, and in the mine ore estimated to be 3,000,000 tons of low-grade material available for the Independence mill. There has been a decrease in high-grade ore sent to the Colorado Springs plant, owing to lessened output of Cripple Creek, and unless there is a material increase in pro-

duction of custom ores in the district it may become necessary, at no distant date, to close the Colorado Springs mill and treat at the Independence all the Portland high-grade ore, as well as the custom ore under contract. The Independence mill was arranged for treatment of rich ore if necessary.

BARNES-KING DEVELOPMENT CO.

PROPERTY: four gold mines, two at Kendall and two at Marysville, Fergus county, Montana.

OPERATING OFFICIALS: G. T. McGee, manager. At the North Moccasin: J. F. Reilly and C. A. Morgan in the office; T. W. Heatherly in the mine; A. E. Wordell in the mill; and E. G. R. Mannwaring, assaying and engineering. At the Piegan-Gloster: J. H. McCormick in the mill; J. W. Rogers in the office; William McClean, engineering; and J. C. Hardy, assaying. At the Shannon: J. W. Johns in the mine, and F. L. Eccles in the office. And at the Kendall: A. B. Fox.

FINANCIAL STATEMENT: profit from operations in 1917 totaled \$444,254. This, with \$324,825, balance from 1916, made available the sum of \$771,819. No. 3 dividend absorbed \$40,000, leaving \$731,819. Current assets at end of 1917 were \$265,669, less \$35,747 current liabilities.

DIVIDENDS: 10c. per share, equal to \$40,000, was paid last year, and one of similar amount in February 1918. Total to date is \$140,000.

DEVELOPMENT: North Moccasin mine has little ore in reserve. Work at the Kendall is by open-cut. In Piegan-Gloster 4565 ft. of work was done, and reserves are 3500 tons of \$14 and 3200 tons of \$12 ore. Shannon shaft is being sunk to 650 ft. depth. New openings totaled 1904 ft. Broken ore in stopes is 5000 tons of over \$15 grade, and 1500 tons of similar material in pillars. Two options on other properties were given up.

PRODUCTION:

	Mine	Tons	Value per ton	Bullion sales	Costs per ton
Kendall	7,923	2.95
North Moccasin.....	26,790	8.53	\$227,925	\$6.006	
Piegan-Gloster	20,525	10.43	210,311	7.991	
Shannon	32,359	15.17	492,684	5.265	

Expenses were reduced 30.1c. per ton at the North Moccasin and \$1.229 at the Shannon, but increased just \$10 at the Piegan-Gloster.

Reports are given in commendable detail.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

HELP LAUNCH A SHIP

*Who says we can't build ships?

Come on, you loyal American mechanics, masters of familiar trades, and brand this 'made in Germany' insinuation by building a bridge of ships to Pershing!

You can't do your country a greater service than by exchanging your good American brawn and skill for good American

to win. We must have them to keep the wheels of American industry moving and American labor employed in the factories.

The Shipping Board has the money, the materials, and the yards to carry out this 6,000,000-ton program, but it needs men to assure these thousand yearly launchings which will hurl their tidal wave toward Germany. There must be an immense reserve of earnest skilled labor to draw on as fast as plants are completed in the yards and the housing provided.

This, then, is the purpose of this message—to ask your enrollment as a shipyard volunteer, for work in the shipyards when needed. Back up Uncle Sam and the millions of your brother workmen by your enrollment.

This does not mean that you are to give up your regular job and rush off to some shipyard that, at the moment, may not be able to accommodate you. Your enrollment simply shows that you stand ready, when called upon, to do a par-

THE MAN OF THE HOUR

THIS IS YOUR BADGE OF HONOR—WEAR IT PROUDLY

ticular job for a particular wage in a particular place. Everything will be in readiness for you, and you will lose no time. So highly does the Government think of your services that you are placed in a deferred class in the draft, as long as you are working on ships.

"But," you say, "I've never worked on shipbuilding."

That's exactly why Germany thinks that America cannot build ships. Germany knows that there are not enough men in America who have actually worked on ships to make more than a tenth of the ships needed if we are to do any fighting worth while.

Here is where you American workmen can fool the Kaiser.

Ships are not things of mystery; they are merely big buildings afloat—the product of everyday skill and industry—and the American mechanic (hats off to him) can build them.

Familiar trades—your trade—are the ones that build ships; and almost all trades are represented. Two-thirds of the occupations required in shipbuilding are common to other industries, like boiler making, car building, bridge building, carpentering, and machine-shop work. The list given later indicates some of the classes needed. Read it carefully and see how you qualify. If you possess the right sort of train-

dollars—in the shipyards; and you'll do as much to win the War as the men dependent upon you in the trenches. Ships and men constitute the pivot on which the destiny of this country turns, and Uncle Sam is looking for 250,000 U. S. shipyard volunteers to build them.

Listen! Every rivet driven in the shipyards brings us nearer to the successful termination of the War. To do our share our shipbuilding program demands 6,000,000 tons per year, or over a thousand ships. We must have them in order

*Editorial of the Associated Business Papers, New York.

ing now is the time to rally round this movement and wear a Badge of Honor. This button, issued by the United States Shipping Board, shows that the wearer, through enrollment in the United States Shipyard Volunteers, has placed the welfare of the Nation above all else and stands ready by his labor to help throw across the seas a bridge of ships by which the armies of the United States can pass to do their duty on the fields of France. To wear this button is a sign of distinction. It truly stamps the owner as the man of the hour, in whose hands rest the happiness and security of every man, woman, and child in this country.

Come on men—250,000 of you! Your Government is asking that you answer the rattle of German machine guns with the rattle of the riveter. It is asking you, for the present, to prove that you are the marrow of Americanism by going on record with an expression of your willingness to help build ships where you are needed; and it meets you half-way with good wages.

Can you turn a deaf ear to the call? Where can you qualify in the following list?

The classes of skilled workers needed are the following:

Acetylene and electrical welders	Foundry workers
Asbestos workers	Laborers, all kinds
Blacksmiths	Loftsmen
Anglesmiths	Template makers
Drop-forge men	Machinists and machine hands, all sorts
Flange turners	Helpers
Furnace men	Painters
Bolter makers	Plumbers and pipe fitters
Riveters	Sheet-metal workers
Reamers	Coppersmiths
Carpenters	Shipfitters
Ship carpenters	Structural iron workers
Dock builders	Riveters
Chippers and calkers	Erectors
Electrical workers	Bolters up
Electricians	Other trades
Wiremen	Cementers
Crane operators	Crane men

Edward N. Hurley, head of the United States Shipping Board, is the mouthpiece of Uncle Sam in this call for shipyard volunteers. He has complete information on hand, ready to mail you, regarding method of enrollment and other details you may want to know. The coupon below is for your convenience in writing. Don't delay. Fill in the information asked for, clip and mail. Your action in this matter will bring you full particulars.

Show that you are interested by clipping the coupon now, while it is before you. The full story will then be mailed you.

Edward N. Hurley, Chairman,
U. S. Shipping Board,
Washington, D. C.

I wish you would send me at once further information, telling me how I can enroll as a member of the U. S. Shipyard Volunteers of the Public Service Reserve for employment in shipyards and so help win the War.

DUPLEX TRUCKS IN EASTERN BLIZZARDS

With snow banked on the Lansing, Michigan, streets two to three feet deep during the recent blizzard which swept the Middle West, Duplex 4-wheel drive trucks relieved the suffering in scores of coalless homes by delivering fuel when it was impossible for teams and sleighs to make headway through the snow-drifted highways. For two days and nights, the only means of coal delivery was with the Duplex trucks which the Duplex company placed at the disposal of the Lansing Fuel Committee. Coal was taken to the homes of poor and rich alike, baskets and bags of fuel being left on porches. Then the Duplex trucks would plow through the drifted streets to other homes, many of which were without fuel of any kind. While several Duplex trucks were delivering fuel, others were hauling street-cars which had been stalled for hours.

In its storm story, the 'Lansing State Journal' published the following statement: "When street-cars were held up this morning it began to look as if they would be frozen to the tracks until the next warm spell, but somebody thought of the Duplex 4-wheel drive trucks and a couple were hurried down from the factory. They hooked onto street-cars and plowed their way down the street. It took them about three minutes to cover the same distance that the street-cars, under their own power, had covered in three hours. All over the city the Duplex trucks answered the S. O. S. calls from stalled cars and gave them lifts. The big trucks seemed to be able to pull anything as long as they could get a foothold."

H. M. Lee, president of the Duplex Truck Co., asserts that the dependability of Duplex trucks under most adverse weather and road conditions, was clearly demonstrated during the severe blizzard and snowstorm. He says: "The Duplex trucks were the only means of transporting fuel for nearly 48 hours, and the wonderful pulling power of the trucks was a surprise to some of our own drivers. The trucks not only plowed through snow-drifted streets, but hauled huge loads of fuel up steep grades to make deliveries in districts that were entirely without fuel. The local fuel committee informs me that but for our trucks many families would have suffered terribly."

COMMERCIAL PARAGRAPHS

THE STAUFFER CHEMICAL Co. is erecting a \$100,000 plant at Vernon, California, for the manufacture of hydrochloric acid.

MINERALS SEPARATION & REFINING Co., of Manhattan Bdg., Chicago, recently installed a plant at Indiana Harbor, Indiana, and is operating a special process for refining ores and metallic residues. Company is particularly interested in refining tungsten.

CORRECTION: Statement in this section of MINING AND SCIENTIFIC PRESS, issue of January 26, the paragraph 'Everything for Mine and Industrial Safety' is misleading. The FLEUSS PHOTO apparatus, as described in the catalogue of the Mines Safety Appliance Co. of Pittsburgh, is no longer handled by that company as sub-agents for H. N. Elmer, general agent for North America; and can be obtained solely through H. N. Elmer, 1142 Monadnock Block, Chicago, Illinois; and E. D. Bullard, 288 Market street, San Francisco, California, his Pacific Coast representative.

WELDON G. WILCOX has been appointed advisory engineer of the POWDERED COAL ENGINEERING & EQUIPMENT Co. of Chicago. Mr. Wilcox is a graduate of Syracuse University, 1906, and a Wisconsin, 1909. From 1909 to 1911 he was in charge of research work at the University of Wisconsin, and from 1911 to 1913 was research chemist with the National Carbon Co. Cleveland, Ohio. He was production engineer with the Cleveland Electro-Metals Co. in 1913 and 1914, and from November 1914 until February 1 of this year was assistant superintendent of the Aluminum Company of America, at Massena, New York.

HEARST wrote a characteristically impudent and sophomoric letter for use as an 'editorial' in his many organs of misinformation on March 8. He "cannot get so violently excited as some people over the possible effects in Europe of the present war." We have noticed that; he has no ranch in Europe. He pats the President on the back and says that "we ought to forget everything we have ever said against him." We do not forget some of the despicable things that Hearst has said, the rankly disloyal suggestions he has made, the malicious meanness of his prostituted journalism.

FERRO-MANGANESE is selling at \$250 per ton for the domestic product. Consumption is greater than the supply, and new sources of the alloy are important. The latest producer is the Anaconda Copper Mining Co., which is to commence within five months. Five furnaces are being constructed at Great Falls, each to reduce 250 tons of manganese ore daily, making a total of 90 tons of ferro-manganese. This product will go into 10,000 tons of iron per day at Eastern steel works. It will also release 100,000 tons of shipping per annum, now engaged in carrying manganese from Central and South America to the United States. Ore will be mined from Anaconda's Butte properties and adjacent districts. Cheap electric power is available from the Montana Power Co., which is an important factor in the mining industry of Montana. What type of electric furnace is to be used in making the alloy is not known yet. Thus Anaconda adds to its metallurgical triumphs of huge blast and reverberatory-furnaces, reduction works, electrolytic copper and zinc, and precious metals; rivaling in variety of products the works at Trail, British Columbia.

PRODUCERS of copper are looking anxiously to the next price-fixing date in June. They failed to obtain an increase above 23½ cents when the price was adjusted a few weeks ago. The fact of an increased output at the Government figure weighed against their petition for better terms, although the argument was valid only in so far as it indicated that the mines were not being operated at a loss. A new factor has now been introduced, and it may prove important. The general increase in wages and in the prices of supplies has affected refineries as well as mines and smelters, but no higher charge for re-

fining has appeared as yet in the estimates of cost for producing the finished metal of commerce. The refining is done under contract with the producers, the agreements usually being made for a long term of years. Although the mining companies to a large extent are interested financially in the refineries, this does not alter the fact that this expense is a direct charge against their output, and the claim is urged that refining now costs nearly three-fourths of a cent per pound more than it did before the War. It is said that the refining cost per ton of blister copper has risen from \$17 per ton one year ago to \$23 at the present time. In consequence the refining companies have announced that the rate must be advanced, or the works will be forced to close. The demand of labor for better wages, stimulated by the prevalence of the custom of manufacturing on the basis of cost plus 10%, has intensified the difficulty of maintaining an efficient force, and it can be met only by raising the rate on the copper treated. The producers are expected to concede the necessary increase, thus diminishing their profit for the present. Their action would appear to be justifiable, and may be regarded by the Government as warranting an increase in the official price of the metal.

BINOCULARS and field-glasses are so urgently needed by the Navy that a second appeal has been issued to the public to turn over such instruments, in exchange for which a nominal price of one dollar will be paid, and a receipt will be given by the Assistant Secretary of the Navy. If not destroyed the glasses will be returned at the end of the War with marks of service upon them that will give them enhanced value as precious memorials of the great struggle for freedom. The art of making lenses had not been cultivated extensively in this country in the past, so that competent workmen and the necessary equipment are not available for meeting the extraordinary needs of the moment. Although every factory in the United States and France is working at full capacity, thousands of officers will be without the aid of suitable field-glasses for watching against the attack of the Enemy unless our people make a prompt and whole-hearted response. When the imperative necessity is understood no one possessing suitable instruments will fail to render this contribution to help in protecting those that risk their lives in the service of the Nation.

The Flotation Appeal

"A tired man": these were the last words of the learned counsel for the Appellant when concluding his argument before the U. S. Circuit Court of Appeals for the Ninth Circuit in San Francisco on March 8. Most of those that had listened for five hours to the technical debate were likewise weary, but it was the weariness of long-sustained interest, not boredom. Half an hour before the judges arrived every seat in the small chamber was taken and the space behind the rail was crowded. The audience, necessarily small, was representative; besides the array of legal talent, we noted Mr. John Ballot, chairman of Minerals Separation, supported by Messrs. Seth Gregory, E. H. Nutter, A. H. Higgins, G. A. Chapman, and W. M. Grosvenor. The Appellant's side of the controversy, aside from the attorneys, was represented by Messrs. N. Bruce MacKelvie, James L. Bruce, B. H. Dosenbach, and E. W. Engelmann. Mr. D. C. Jackling, although in town, was absent. Among the onlookers were E. P. Mathewson, Thomas J. Barbour, R. B. Yerxa, and Dudley H. Norris. Several elderly men of the prospector type suggested the miner's stake in the contest. Punctually at 10:30 the three judges filed into court; they were William W. Morrow, Erskine M. Ross, and William H. Hunt. Judge Ross, the only one of the three that had sat in the Hyde appeal, presided.

Mr. J. Edgar Bull opened for the Appellant [Defendant], the Butte & Superior Mining Company. A veteran, he spoke without waste of energy, clearly, and quietly. To each judge he handed a copy of patent 835,120. He began with a frank acceptance of the decision of the Supreme Court of the United States, in the Hyde case, as "the law of the land." His clients had used the prohibited fraction of 1% of oil before that decision, but since then always more than half of 1%, and latterly more than 1%. He contended that the use of any proportion above 0.5% did not infringe the patent as construed by the court of last resort. Turning to the text of the patent, he divided the claims into those specifying "a fraction of 1%" and those mentioning "a small quantity." No. 9, 10, and 11 were the 'small quantity' claims. Before reviewing the decisions of the successive courts, he gave to each judge a reprint of the previous opinions for convenience of reference. Emphasis was placed on the limitation of the quantity of oil as being the essence of the invention. He read paragraphs from the opinions in support of this contention. The Supreme Court had agreed with "your Honors" except as to the patentability of this limitation of oil, whereas Judge Bourquin, of the Montana court [from whose decision the present appeal is taken], had reaffirmed his opinion in the Hyde case, even going so far as to repeat the errors condemned by the Supreme Court. To what fraction of 1% does the Supreme Court limit the patent? To one-half of 1%. The Court said that "the patent must be confined to the results obtained by the use of oil within the proportions often described in

the testimony and in the claims of the patent as 'critical proportions' 'amounting to a fraction of 1% on the ore'." The critical quantity is usually one-tenth of 1%, sometimes up to half of 1%, but never more. Here Judge Morrow asked for a definition of 'critical quantity.' Then came quotations from statements by the patentees, their witnesses and counsel, to show how they had agreed in limiting the critical proportion to less than half of 1%. Mr. Bull read the colloquy between Justice McReynolds and Mr. Kenyon [given in the brief, which appears on another page of this issue], whereat Mr. Kenyon gave signs of discomfort. Judge Bourquin's view that an excess included a fraction would be tenable if the patentees had been the first to use oil in flotation, but not if their invention was the use of a limited quantity, for the 'small quantity,' down to 1%, was old. Shall the public be denied the right to do what it had done before the patent? The decision below had ignored the Supreme Court's opinion on the 'small quantity' claims. The Appellant company used more than 1% because the Supreme Court compelled it to use more than half of 1%. "A burnt child dreads the fire." It had lost a million dollars per annum by using an excess of oil. Apparently Minerals Separation had abandoned the contention that mineral oil was "inert and useless," for their licensees use it in their oil-mixtures. Mineral oil is not a froth-producer, they contend, but this is contradicted by their own patent, in which they designate the oil as "an oily liquid having a preferential affinity for metalliferous matter." It is admitted by them that mineral oils have a greater 'affinity' than vegetal oils. Nor is it true that mineral oils have no froth-producing qualities. Mr. Bull cited from Minerals Separation reports and patents. The mention of oleic acid brought the question from Judge Hunt: "What is oleic acid?" We recalled hearing the same query made in a cracked voice by old Lord Halsbury when the Judicial Committee of the Privy Council was trying the Elmore v. Minerals Separation case in November 1913. This question in the midst of a flotation trial is as pathetic as Pilate's "What is truth?" Then Judge Morrow asked, "Is there a difference in the affinity of oils for minerals?" Mr. Bull replied affirmatively, adding that this applied to mineral and vegetal oils alike. It is a matter of 'cut and try.' Whereupon the same Judge asked, "The production of froth and the affinity for minerals are different qualities?" "Yes, your Honor." Both qualities are needed. Mr. Bull took pains to establish the function of the mineral oil, and, having done this, he proceeded to discuss the disclaimer filed by Minerals Separation after the Supreme Court had invalidated claims 9, 10, and 11 (the 'small quantity' claims) of the patent. The Supreme Court had found the patent good in part and bad in part; the disclaimer was to relinquish the over-claim. Plaintiffs [Appellees], Mr. Bull argued, had not made a proper disclaimer, they still claimed the use of more than 1% where results were the same as when using less than 1%. The disclaimer did not conform to the order of the Su-

preme Court. Mr. Bull had spoken for an hour and a half. As soon as he finished, the reading-desk, facing the judges, was cleared of his documents, to make room for those of Mr. Henry D. Williams, who opened for Minerals Separation.

Mr. Williams spoke with jaunty confidence, reading a large part of his speech. "The text of the Appellees will be the Supreme Court decision." Only a part of that decision had been read. As in the celebrated telephone case, where a tightening of a screw by Bell had converted a machine that could not convey speech into one that could—creating a new art—so "the final step" that the patentees of \$35,120 had taken had been the step in the right direction. He gave an excellent non-technical description of the agitation-froth process. Without a modifying agent—namely, oil—the air would be ineffective in forming a persistent froth, the bubbles would coalesce and burst. The oil maintains the integrity of the little bubbles, so that they do not coalesce but repel each other and rise to make a layer of froth seven inches to three feet thick. Has the Appellant company carried on this process and obtained this result? It admits that it did up to January 1917. What change has it made in its procedure since then, in order to pass from an infringing into a non-infringing operation? Its procedure is the same, but it has added other oils that do not form mineral-froth. It has impaired the patent to the tune of a million dollars per annum. The process is applicable to ores having a metallic lustre, like graphite. All oils have a preferential affinity for metalliferous minerals. The patent covers substances other than oil that have this preferential affinity. It is necessary to make a preliminary test to select the oily substance most suited to the work. Here Mr. Williams handed the judges separate copies of each of the previous decisions. The formation of a froth is the end and object of the first three claims of the patent. The use of an oily substance that does not form a froth is alien to these claims, but any alien oily substance that does not interfere with the making of froth is included. Then followed a recital of the proportions and kinds of oil used by the Butte & Superior in 1916 and early in 1917. With oleic acid half of 1% was the point at which the Cattermole granulation ceased, and the process of \$35,120 commenced. Claim 12 differs from No. 9, 10, and 11 in specifying both the quantity of oil and the agitation required to form an oil-coated mineral in the froth. "The Supreme Court said we must confine ourselves to the fractional proportions, so we wrote a disclaimer and wrote into the claims the language of the Supreme Court, but for the purposes of the case at bar we do not care whether they are limited to 1% or more, for they have infringed in using the oil of the patent in the proportion of a small fraction of 1% on the ore." It was now 12:30 and the Court adjourned until 2. On resuming, Mr. Williams argued that throughout the Supreme Court's decision there was an insistence on the "resulting froth-concentrate" as identifying the invention. Emphasis was

placed on the novel "results," the novelty consisting in the use of an air-lift instead of the oil-lift of prior attempts, the carrying of the metal particles by air-froth in contradistinction to an oil-float. The reference to an "agitation greater than and different from" that which had gone before was a criticism of the things done by the Appellant with prior-art methods, all done with a violence of agitation unnecessary even in the process in suit. It was Cattermole that introduced violent agitation into oil processes. The Cattermole method was the immediate predecessor of patent \$35,120. The colloquy quoted between Justice McReynolds and Mr. Kenyon referred to Broken Hill ore and oleic acid, nothing more. With the Cattermole process it was customary to use kerosene and heavy petroleum until oleic acid was introduced for saponification. On Broken Hill ore petroleum and kerosene would not produce a froth. The varieties of ore are infinite. Preliminary tests are necessary. Mineral oil is not essential to the process in suit.

The argument for the Appellees was continued by Mr. William H. Kenyon. He spoke in a staccato manner and gesticulated nervously. Both sides agree, he said, that this Court had only to read and study the opinion of the Supreme Court. What is the duty that the oil performs in this patent? Is it preferential affinity, or must one go further and inquire whether it has a froth-making capacity? "Does degree of agitation enter into the making of froth?" asks Judge Morrow. "Yes, somewhat," is the reply. "We introduced a special kind of agitation." The Supreme Court recognized that the preferential affinity and consequent coating with oil was old—Haynes patent; that the enhancing of that affinity by acid was old—Everson; that increase of linoyaney was old—Kirby; that increasing the stickiness of the oil was old—Cattermole; but utilizing the froth-forming capacity of the oil was new. The Court below held the same, limiting the fraction of 1% to "beneficial service." The Appellant used only a small fraction of 1% of the oil, pine-oil, that has the froth-making capacity; to evade the patent he added nine-tenths of 1% of oil that won't and can't form froth. Mr. Kenyon then proceeded to rebut the argument that the extra oil used could form a froth. He quoted Higgins's experiments to prove the inefficiency of mineral oil; also Janney and Bancroft to show that kerosene is not a 'frothing-oil.' At this stage the dispute waxed warm. Reference is made to an eleven-hour introduction of evidence as to froth-making efficiency of mineral oils by the Appellant. "Our invention," shouts Mr. Kenyon, "came out of the blue while economizing oil in the Cattermole process. A significant admission—that of economy. It was interesting to note the unhappiness of counsel compelled to listen to the argument of their opponents. Their faces were flushed and they showed uneasiness. All of these manifestations were transferred to the other side when their turn to argue came. Mr. Kenyon quoted Higgins's testimony that he [Higgins] was "never able to get mineral-froth with kerosene." He is interrupted by

Mr. Thomas F. Sheridan, leading counsel on the other side, when he states that fuel-oil always contains some of "our soluble frothing-agent," this being claimed to be outside the record. Mr. Kenyon proceeds to smash the testimony given as to the use of fuel-oil at the Arthur plant of the Utah Copper Company, on the admission that the tanks were not cleaned properly before the experiments. Thus he appears to get even for his unfortunate colloquy with Justice McReynolds. The addition of nine-tenths of 1% of petroleum oil does not avoid the patent, he insists. It is not like the acid, or the fine grinding, or the copper sulphate used by the Defendant; it does not create the result, if it does anything; it does not make the mineral-bearing froth. Here he stopped abruptly, and Mr. Lindley M. Garrison was about to close the argument for Minerals Separation when Judge Ross announced that 15 minutes more would be granted to each side, whereupon Mr. Kenyon resumed. The Appellant does not claim any process of the prior art as his method, only the quantity of oil used. The Supreme Court holds that oil processes do operate in the same way, apart from limitations of oil. "We lose a million dollars by use of a process," says the Appellant, "therefore it cannot be the process defined by the Supreme Court." Columbus sought the East and found the West, yet he made a great discovery. While the plaintiffs were muddling over Cattermole's process they made a great invention based on the preference of air for oiled mineral. A distinguishing feature of the Supreme Court's decision is the emphasis on the "results obtained" as a limitation to the use of the patent. Infringement is involved in using a fraction above or below 1%, if those results are obtained, however camouflaged by dummy oil. He stopped. The Court granted half an hour more.

Mr. Garrison came forward. The ex-Secretary of War looks, acts, and speaks like a successful politician. He speaks loudly, gesticulates freely, slaps the desk liberally, and moves to and fro, barely refraining from looking away from the judges to the spectators. He does not say 'Your Honors' and 'May it please the Court,' but just plain 'You,' evidently deeming himself absolved from the minor courtesies. His only previous appearance in flotation litigation had been before the Supreme Court in the Hyde case. The Supreme Court did not disagree, he begins, with this Court on a question of law, but on a question of fact. Its decision did not turn on economy in the use of oil, but on a new function of the oil never before disclosed, namely, the frothing quality. "If you haven't got a frothing oil you can't get a mineral froth—take water, ore, and oil, and mix them as much as you like." He slaps the desk with gusto. All oils have a preferential affinity for minerals. Select the ones that make froth. None of the mineral oils used by the Appellants will make froth and carry on the process of the patent in suit. None of the oils included in the patent if used to over 1% will produce the result desired in the mill. Appellant uses an oil of

the patent plus other oils. The Hyde case did not include any operation except with the oils of the patent. If the use of the prior art gives the same result it is not our process; if it gives a different result, it is.

Mr. Garrison was followed by Mr. Frederick P. Fish, who closed for the Butte & Superior. Mr. Fish is short-sighted, physically, not mentally; and had a little difficulty in finding his citations. At one point, early in his speech, he was momentarily confused, but his quietly serious manner of discussion was restful after the declamatory style of his predecessor. Mr. Fish did not indulge in gesticulation or rhetorical confectionery; he restricted himself to simple direct statement. The decision of the Supreme Court, he said, is a clear document, so that its meaning cannot be clouded. Claims 9, 10, and 11 are declared invalid, because those claims were not for the specific thing that the Court found to be new, namely, the use of oil in 'critical quantity.' It was an apt phrase to cover one-tenth or five-tenths of 1%. The invention does not go a step beyond that critical point, as determined by the testimony, not by the patent alone. Can the patent stand if it claims all oils, animal, vegetal, and mineral, when you have to hunt through the universe to find the oil that will do the work specified, without stating how you are to select the oil adapted to the particular ore? He quoted from Sulman's testimony to show how much had been done before the discovery was made. The step was a short one. There had been froth in the Cattermole process always. He quoted the Higgins record. At 3% "very little float," and so forth, until the 'float,' or 'froth,' became "vastly increased" at 0.32%. The invention was purely a modification of Cattermole's. The same old froth is made whenever oil and water come together. The same froth was made under less fortunate conditions by Everson, Froment, and Kirby. The new froth differs from the old because there is less oil to coagulate. The froth differs with the proportion of oil. The Supreme Court says that a perfectly definite discovery was made in ascertaining that when you run down oil to the vanishing point you get a new phenomenon—no more granulation, but froth at its maximum efficiency at one-tenth of 1%. Litigation has grown up to beat the exigencies of each case. There is nothing in the patent to warrant the claim based on "our kind of froth." In the British specifications of the patent the phrase "a small fraction of 1%" is used, indicating what "a fraction of 1%" was intended to mean. Mr. Fish quoted Chandler's testimony on the subject, showing that one to four pounds is the practical range according to Minerals Separation. "We have the right," said Mr. Fish, "to pay a million in order not to use the patent rather than pay ridiculous charges."

By request of the Court a moving-picture exposition of flotation was given the following evening, supplemented, on the Monday following, by a demonstration with experiments. An account of these proceedings must be deferred.

DISCUSSION

Compañía de Minerales y Metales

The Editor:

Sir—On March 15, 1917, I had occasion to write you calling your attention to certain erroneous statements published in your magazine of February 17 under the heading of 'Correspondence from El Paso.' You were good enough to publish my letter of explanation in full in your April 7 issue, which we greatly appreciated, as it contained a statement of the facts.

In your issue of September 15, another article appeared which likewise contained several inaccurate and misleading statements with reference to our subsidiary companies in Mexico. At that time I dictated another letter to you, setting forth the facts, but did not send it, thinking that your article was based upon misinformation and had no ulterior motive. It seemed undesirable, therefore, for me to reply at length to the article for fear of treating too seriously a matter which was in fact only of interest to a limited circle.

However, my attention has now been called to the article in your issue of February 9, entitled 'Mexican Mining Law.' This article does not confine itself to a mere statement of inaccuracies, but seems to be permeated with a distinctly unfriendly spirit. From our long and friendly acquaintance I take it for granted that you desire to publish in your magazine only the truth and that this article as well as the ones which have preceded it, in which reference has been made to our subsidiary companies in Mexico, has been based upon the information available to you and that you had reason to believe this information to be reliable. Therefore it naturally follows that if I can show you where your informant has misled you and has submitted statements to you which are contrary to the facts, you will be ready to make the necessary corrections. The inaccuracies to which we particularly take exception are the following:

1. The Compañía de Minerales y Metales, which is the company through which we manage most of our Mexican properties, is not "German owned," as you state. The fact is that the American Metal Co. owns 97.7% of the stock of the Minerales company.

2. Your article contains the insinuation that the properties which we have recently acquired in Mexico have been in some way secured by unfair methods or by improper co-operation with the Mexican government as a result of the mining laws recently enacted in that republic. This we absolutely and unequivocally deny. It is true that we have acquired several properties in Mexico

during the past three years, but we have never acquired any property or any interest in any property which was confiscated by the Mexican government or the sale of which was forced by the intervention of that government. We have in every case acquired property by direct purchase from the owners or by the purchase of stock in the open market where the property was owned by a corporation. Our records of these transactions are open for your inspection if you desire to verify this statement.

3. Your insinuation that our vice-president, Mr. Henry Bruère, had anything whatever to do with the management of our property in Mexico, and the suggestion of any change in the policy of the Mexican government which would redound to our advantage are absolutely without foundation. Mr. Bruère went to Mexico at the invitation of the Carranza government to act as its financial advisor in the reorganization of some of its departments. His acceptance of the invitation was with the full knowledge of our own Government, and while in Mexico he abstained absolutely from having any connection with or interest in the management of any of our properties. Mr. Bruère advises us that he has made no recommendations regarding Mexican mining laws except as a member of the American Mining Committee and then only through action by that committee. Never at any time has he sought special consideration of Compañía de Minerales y Metales, or any other company, or in any other way used his connection with the Government for personal or company advantages.

4. We wish to point out to you also that the extension of our holdings in Mexico has been for the benefit of American interests, and not in any respect for the benefit of German interests. As stated above, 97.7% of the stock of the Minerales company is owned by the American Metal Co., Ltd. This company is, as you possibly know, controlled by British and American interests and its operations are conducted entirely by Americans. It is true that certain minority shares were owned long prior to the War by German stockholders, but these have been transferred to the Alien Property Custodian, who is now represented on our board of directors. It is a source of gratification to us that the foresight exercised by our board in resuming operations and expanding our activities in Mexico has put us in a position where we can now be of material assistance to our Government and its Allies by producing much needed supplies of lead, silver, and arsenic.

You will readily understand why our company takes exception to the manner in which your magazine has in

the past published these inaccurate and misleading articles, and as stated above, we take it for granted that they have been based upon misinformation. We have good reason to believe that much of this misinformation, particularly about our activities in Mexico, has been disseminated by unfriendly interests who are jealous of our success. So as to prevent your publication from being further misled, I want to assure you that we shall be glad to have you bring to our attention any similar reports which may be made to you, and we shall be ready at all times to give you the facts in reference to any transaction in which you are interested. It follows that as a matter of fair dealing, you will give this letter the same publicity that you have given to the articles themselves.

The American Metal Co., Ltd.,

By OTTO SUSSMAN,

New York, February 19.

Vice-president.

The Editor:

Sir—Your editorial entitled 'Mexican Mining Law,' in the issue of February 9, contains many gross misstatements about the *Compañía de Minerales y Metales, S. A.* I take it that you aim to be exact in your editorial statements, even about those whom you dislike. Hence this letter.

I am an employee of the above-named company and have been since 1909, have had access to their files for several years past and have read them industriously, for several reasons, and I know whereof I speak. The *Compañía de Minerales y Metales S. A.* has not "been gathering up properties relinquished by other aliens in Mexico." All properties leased or bought have been taken over from pre-revolutionary owners, many of them aliens themselves, and not at a "pittance" as your editorial states, but at a valuation which is in accordance with the usual in like transactions. You cannot substantiate your statement with a single instance.

If the *Cia. de Minerales y Metales, S. A.* have taken over and are operating coal and metal mines, smelters, and railroads, it is because they have believed that revolutionary times in Mexico will not last always and they have had the financial courage to invest their money at a time when everyone else held off. Their acquisitions either through lease or purchase have been made through public documents following straightforward, honest, and above-board negotiations with those concerned and not in a manner implied by your word "wily." And if they have succeeded in operating their mines under present conditions it is because they had the foresight to buy railroad equipment when it could be bought and have used the industry, energy, patience, persistence, and courage required, and not because they have been favored. The superintendents of all their units are Americans, who, had they worked for any other company having the above-named qualifications and not afraid to invest their money would have accomplished the same.

The Mexican has no more respect or contempt for the

American than he ever had. Any American who comes to this country with the necessary qualifications for operation in Spanish America, who behaves himself, and starts up his mines will find himself welcomed. Conditions have changed here; so have they in other countries. And whoever comes here and starts any industry is helping the people of Mexico at a time when they need help. And if you, Mr. Editor, also want to help Mexico you can do so much more effectively by doing some constructive thinking along the lines of Mexican mining law. Your editorials will be read and thought about more than you know. If Mr. Bruére has suggested that a change in policy is needed it is not because he is the representative of the American Metal Co., but because he is sincere in his work, and you can be sure that most all owners of mining property in Mexico, irrespective of their nationality, agree with him. If you will compare the amount of money needed to locate and hold a given area of ground under the present Mexican system and the American system you will see that in both cases it is beyond the means of the ordinary Mexican peon or vaquero, and you will find that the difference is against the American system.

Your statement that "meanwhile the mines are passing into the hands of the most exacting owner he could have selected, etc." calls for comment. The personification of your word "exacting" in this case is honest, intensely human, progressive, and liberal. Ask any of their engineers who stay in Mexico under trying conditions when they could do as well financially in the States. The sense of loyalty between men still persists.

The source of your information is unreliable and untruthful. Run it down with an honest open mind and a scientific regard for facts and you will find that you have little to expose as regards the past and present actions of the *Compañía de Minerales y Metales, S. A.*

FRANK J. NAGEL.

Santa Eulalia, Mexico, February 23.

[We have not hesitated to give space to Dr. Sussman and to Mr. Nagel for their explanations, and courteous protests. The references made in our editorial columns to the subsidiary companies of the American Metal Co. operating in Mexico have been based upon information from correspondents whom we believe to be unbiased except by loyalty to the United States and the great cause to which our country is committed. The fact that the American Metal Co. owns 97.7% of the Mexican subsidiary is not as convincing as it might be, for the reason that the American Metal Co. has always been closely associated with the *Metallgesellschaft, Henry R. Merton* [true name Cohen] & Co., and other German firms, as ascertained by the Federal Trade Commission. See our issue of January 19, in which that part of the report of the Commission is given verbatim. We have known the principals of the American Metal Co. personally for many years and know them to be men of high character, but distinctly German, even when naturalized citizens of the United States or of Great Britain. Now it is a fact

that, by German law, the naturalization of a German in a foreign country does not involve a complete break with his mother country; on the contrary, the German government refuses to release its claim upon German citizens even after they have sworn allegiance to another country. Moreover, as Mr. Gerard has stated recently, "Germany does not recognize the American citizenship of a person born in Russia." Other governments, for instance, those of Great Britain and the United States, disown the citizen that surrenders his nationality by naturalization; Germany does not. For that reason we are justified in regarding the naturalization of a German as a legal process intended to give him sundry business advantages without corresponding obligations. If we remember correctly, the last German law on the subject was passed in July 1913. We have seen the text of it. This does not mean, and we do not imply, that Dr. Sussman and his friends are not loyal Americans, but it does mean that naturalization is not proof to the contrary. As to the Compañía de Minerales and its operations in Mexico, it is in high favor with Carranza, who is on cordial terms with our chief Enemy. The information on which we based the expression of our opinion was that of our correspondents after it had been confirmed by conversation with bankers and other responsible persons at El Paso. We concede frankly that the categorical denial of Messrs. Sussman and Nagel will have due weight, particularly with those that know them.—Editor.]

The War-Minerals Committee

The Editor:

Sir—The bill to control war-minerals, as outlined by Mr. Westervelt, chairman of the War Minerals Committee, should be vigorously supported by thinking and patriotic Americans, so that Congress will enact it without delay. In a republic there is always strenuous objection to anything that savors of government control. It might have been better, therefore, to have called this an efficiency bill for providing the necessary war minerals. It would seem as if the suspension of business on account of a shortage of coal were most opportune, as it teaches us how promptly and how forcibly we must act to prevent shortages in other industries. If our organization is so poor, or our facilities so bad, that an unusual stretch of inclement weather causes a complete breakdown, what would we do in the face of an enemy invasion, and what will become of our troops abroad in case of entrapment of our transport and supply service?

The United States is now at war with two nations that, through careful study and preparation together with efficient organization of their men and material for years, have occupied large parts of Europe outside of their domains. The three and a half years of effort of nations many times greater and richer in resources and materials have not forced these invaders to return to their own territory, or apparently to modify their plans of expansion. The European nations arrayed against Germany and Austria have not been able to suppress

their enemies; they are wearing themselves out; their man power is reduced, and their resources impaired. It has become necessary for the United States to supply men, material, and food to carry the War to a decisive victory. The entrance of the United States into the War by the votes of the representatives of the people establishes the right of the Government to its men, materials, and supplies. It is now necessary to determine the most efficient organization for providing the materials and supplies for the military forces and for the protection of the people in their various walks of life. Administrators have already been appointed for food and coal supplies, and for the operation of the railroads; but there is no adequate organization to provide the Government with war-minerals. I have no doubt that Congress appreciates the necessity fully, and that it will hasten to pass the necessary laws creating an administrator or a director to control the war-minerals or to provide for procuring them as fast as they may be needed. The object of this letter is not to argue at length for the passage of a bill the expediency of which cannot be doubted, but to call attention to features which should be included in the bill to make it effective.

It must be borne in mind that at this time conditions are abnormal. Production and commerce are greatly demoralized and interrupted. Also that the war-mineral requirements of the country and of our Allies are vastly different from those in times of peace. Our first duty, then, is to provide for the taking of a complete census, (1) of the requirements of the country for its military forces and for the maintenance of its people, (2) of the requirements of our Allies, (3) of our existing resources, (4) of our potential resources, (5) of the markets of the world where deficiencies can be made up, and (6) of our mills, smelting, and other metallurgical plants, and their availability or adaptability for producing necessary materials and supplies.

To be of value, these facts must be collected and segregated by a corps of specialists, men of reputation as geologists, mineralogists, mining engineers, metallurgists, trained for the operation and management of operations under investigation. The work must be directed by an independent and unattached operator or engineer of wide experience. He must have full authority to demand complete reports from owners and producers, and to check them up by members of his staff sent to make examinations in person.

The second great need is the procuring of these necessary war-minerals. This must be done through a bureau or department in the organization of which the following must be borne in mind: (1) to work without conflict between the several governmental departments and to the best advantage of the different departments; (2) to prevent disastrous delays; (3) to compel just and reasonable prices, both to the producer and to the Government; (4) to prevent hoarding of materials to the detriment of the country or the advantage of its enemies, or for the purpose of gaining unfair profits; (5) to send commissions to foreign countries to procure necessary supplies,

which cannot be procured at home, and to prevent our enemies from procuring said supplies for their own use or to our detriment by depriving us of them; (6) with authority in cases of necessity, such as the unwillingness of the owners of plants to meet the fair demands of the Government, to operate mines, mills, smelting, or other metallurgical plants, whenever necessary, and when it is apparent that, under other conditions or in other ways, the requirements of the country cannot be met; (7) with authority to build mills, smelters, or other metallurgical plants whenever necessary and when it is apparent that the owners cannot or will not do same upon the Government's recommendation, and when necessary to meet the requirements of the Government; (8) to contract for necessary supplies in the quantity, and at the prices, that will justify or protect patriotic citizens to undertake new business, thus relieving the Government of a portion of its burden; (9) to buy material and supplies, and to distribute the same to the manufacturers in the way that will assure to the Government its finished articles when needed; (10) to requisition materials and supplies on sight when necessary, when it is found that the owners refuse to treat with the Government, or to accept reasonable offers of the Government for purchase; (11) to organize a corps of trained specialists for the inspection of mines, mills, or metallurgical plants, to advise and assist in the operation of these plants, to determine whether the work at these plants is carried on efficiently and without waste, and to provide the information necessary for the chief of the bureau to enforce modification of plants when it has been demonstrated that there is inefficiency and waste; (12) to organize a trained staff whose business shall be to become fully informed as to the requirements and plans of the administrator, and to check up and see that his orders are being promptly carried out. This staff should further check up independently, but under the direction of the administrator, the orders as given out so that no details may be omitted, and that the orders can be executed according to schedule.

There is no desire, I believe, on the part of the Government, to usurp the rights of the people, but there is a great necessity to provide an organization which will furnish people with the necessities of life, and its fighting forces with the weapons with which to fight successfully that the War be brought to a just termination. Our two Allies, who have been able to check the advances of the Enemy, adopted a system fully as drastic as the one here proposed. They have found it necessary to send representatives to all parts of the world with authority and with money to secure the necessary materials for their armies in the field, and for the maintenance and existence of the people at home, and they are trading in the supplies which they have acquired in foreign countries not only with other foreign countries, but with their own Allies.

I have just returned from a two years' trip through Portugal and Spain, and have come into personal contact with the methods adopted by some of the countries

at war in their efforts to obtain supplies. My operations, and those of my American associates, were seriously handicapped through the activities and the zeal of at least two of the government agents of the Allies of the United States, for which in all probability, sooner or later, an accounting will be made, but at the time these activities were fully supported by their home governments.

The market conditions in the United States concerning certain war-minerals are most unsatisfactory. Fluctuations of price, due in part to manipulation, have been discouraging, and have caused the shut-down of many properties which should now be operating to their maximum capacity. Methods now in vogue for determining values, and the arbitrary methods adopted by many purchasing companies, have added to the confusion, increased dissatisfaction, and further curtailed production. Even litigation has been employed as a means to curtail production. Whether this be inspired by the Enemy, or results from the uncontrolled state of business, matters not; the fact is, that our fighting forces are held back, the War is protracted, the Enemy is encouraged, and the loss of life and property thereby is incalculably increased.

GEORGE WARREN TOWER JR.

New Rochelle, N. Y., January 19.

Sea-Water for Flotation

The Editor:

Sir—Some time ago I investigated the effect of seaweed on the rate of corrosion of condenser-tubes by seawater. The solution, in which the test-pieces were immersed, was not changed and I noted that after a few days it became rather oily in character and could easily be made to foam. I would suggest to the correspondent whose interesting contribution you published in your issue of February 2, that he try such a solution as a frothing-agent in his tests.

PAUL T. BRUHL.

Aurora, Nevada, February 7.

LYCOPodium is a vegetable material which, before the War, was used for dusting or coating the molds in foundry practice, in order to prevent the sand from clinging to the castings. Lycopodium came exclusively from Russia and there is none available now. Experiments have showed that by a centrifugal process the dust, which is precipitated from the gas exhalations of the drying apparatus in the works where coal or lignite is briquetted, can be used successfully to replace lycopodium. The light particles of dust, which contain a large percentage of paraffin, have the same properties as lycopodium, as may be seen when water is poured upon them.

ELECTRIFICATION of mine hoists in 1917 did not continue at the rapid pace set during 1916, yet over 22,000 hp. was installed.

The 2000-Ton Leaching Plant at Anaconda

By FREDERICK LAIST and H. J. MAGUIRE

The equipment and operation of the 2000-ton copper-leaching plant at Anaconda has been previously described by Laist and Aldrich. It is not intended to duplicate the information contained in the above paper except in so far as it may be required to give a comprehensive view of the methods employed. The plant has now been in operation about two and a half years, treating the accumulated concentrator sand-tailing from the dump. By November last 1,432,617 tons of the 20,000-000 tons of tailing, estimated to have been in the dump, had been treated.

This copper-leaching process makes a very high recovery when treating a de-slimed uniformly sized sand. These conditions, however, are so hard to obtain that it can scarcely be expected that the leaching process will compete with flotation on a freshly mined ore, but, with the class of material, partly oxidized as it is, which this plant is treating, it is hardly possible for the flotation process to compete successfully. The wide demand for sulphuric acid has made it exceedingly difficult for the leaching plant to obtain anywhere near the quantity required. The idea, under these circumstances, has been to try to produce the greatest quantity of copper with what acid might be available, rather than to reduce the capacity for the purpose of a better recovery.

The equipment consists of the following:

- 6 sand-storage bins, capacity 6000 tons.
- 28 20-ft. diam., 6-hearth McDougall furnaces, capacity 100 tons per furnace.
- 28 coolers, one for each furnace.
- 16 cement-lined steel mixers.
- 10 lead-lined redwood tanks, 50 ft. diam. by 14-ft. stave, capacity 1000 tons of calcine each.
- 5 unlined redwood tanks for solution-storage, 50 ft. diam. by 14-ft. stave.
- 12 concrete precipitating-launders 5 ft. deep by 10 ft. wide, with a total capacity of 35,300 cubic feet.
- 7 4-in. hard-lead centrifugal pumps, capacity 60 tons of solution per hour.

Belt-conveyors for carrying the sand-tailing to the furnaces and the calcine from the furnaces to the leaching-building.

PRODUCT FED. An average screen analysis of the sand-tailing dump is given below:

Mesh	Opening mm.	Cumulative %
20	0.926	22.6
40	0.429	64.7
60	0.260	82.0
80	0.207	89.1
100	0.149	93.8
160	0.0856	97.7
200	0.0763	98.5
-200		1.5

The average metallic content is about 0.65% copper, and 0.50 oz. silver per ton.

The screen analysis of the sand-tailing treated during July last is:

Mesh	Opening mm.	Cumulative %
14	1.18	4.26
20	0.833	15.58
28	0.589	32.44
35x	0.417	51.92
48	0.295	66.05
65	0.208	77.50
100	0.147	87.29
150	0.105	93.52
-150		6.48

The following shows the analyses of the sand tailing for the first half of 1917, and also for July and August:

	H ₂ O %	Cu %	Ag oz.	SiO ₂ %	FeO %	S %	Al ₂ O ₃ %	CaO %
July	4.49	0.72	0.54	81.5	3.3	2.7	7.9	0.3
August	4.74	0.72	0.51	81.6	3.2	2.9	8.1	0.4
Half-year	6.53	0.77	0.59	81.0	3.4	2.9	8.3	0.2

The details of operation in regard to roasting are identical with those given in a previous paper. To assist the furnace-man in the control of roasting, a pyrometer is inserted in the fourth hearth of each furnace, and the recording instrument, one for each set of four furnaces, is set up at a convenient place on the firing floor. The temperature which gives the best results is about 950°F. The temperature of the third, or fired hearth, is about 1050°F. The range of temperature never varies more than 30°F. either way from the temperature desired. When a furnace-man has become accustomed to this kind of work and has a reasonably good grade of coal, he can hold the temperature at the desired point for eight hours with no difficulty. One furnace-man fires four furnaces with two fire-boxes to a furnace. The calcine after roasting is cooled to a temperature of about 125°F., and a little water is added to it in the mixers to lay the dust before discharging to the conveyor-belt on its way to the leaching-tanks. A sample of the roaster work is here given. The time-period is taken at random from the records for 1917:

	Feed		Calcine	
	H ₂ O %	S %	Total Sulphur	Sulphur as sulphate
July				
8	4.00	2.65	0.55	0.26
9	5.00	2.63	0.54	0.24
10	5.00	2.77	0.54	0.26
11	4.50	2.76	0.54	0.24
12	4.75	2.71	0.55	0.27
13	4.50	2.80	0.55	0.25
14	5.00	2.47	0.55	0.25
15	5.00	2.62	0.52	0.26
16	5.00	2.76	0.50	0.25
17	5.00	2.57	0.55	0.26
Average	4.78	2.67	0.54	0.26

It will be noticed that the sulphur in the calcine in sulphate form is almost half that of the total sulphur. The quantity of water-soluble copper is almost identical with that of the sulphate-sulphur produced.

A screen analysis of calcine from the leaching-plant treated in July is as follows:

Mesh	Opening mm.	Calcine	
		Solids %	Solids cum. %
14	1.18	4.58	4.58
20	0.833	12.09	16.67
28	0.589	17.96	34.63
35x	0.417	19.48	54.11
48	0.295	13.92	68.03
65	0.208	10.92	78.95
100	0.147	9.14	88.09
150	0.105	5.78	93.87
-150	6.13	100.0

LEACHING. The solutions are pumped to the top of the charge, thus making all percolation downward. The rate of percolation varies with the different solutions. The first, or No. 1, solution will percolate at a rate of about three inches per hour, while the rate for the hot wash-water is from 10 to 12 in. per hour. The slow rate of the No. 1 solution is partly due to its being more viscous than the succeeding solutions, and partly to its being the pioneer solution. To thoroughly saturate a charge of calcine requires about 25% of its weight of solution. This will fill the space under the cocoa-matting and the false bottom, and will also cover the top of the calcine completely.

There are five stock-solution storage-tanks.

	Cu %	H ₂ SO ₄ %	NaCl %
No. 1 solution-tank.....	0.9	5.0	9.5
No. 2 solution-tank.....	0.3	2.0	6.5
Copper-solution tank	1.9	1.5	8.0
No. 1 wash-solution tank	1.0	6.0
Wash-water drainage-tank	0.2	1.0	6.0

When a tank has been filled with calcine the drain is closed and the No. 1 solution is pumped on until the charge is thoroughly saturated. It is customary to spread about two or three tons of salt on the charge just ahead of this solution. After saturation has taken place the drain-valve is opened and drainage to the copper-solution storage-tank begins. Fifty tons of No. 2 stock-solution is then pumped on, thus keeping a head of solution on top of the charge. When the drainage has progressed to the point where the solution just disappears under the calcine the drain-valve is closed and 10 tons of salt is spread over the charge. On top of this salt is added the strong-acid solution. This is made up on the charge by adding 60°B. sulphuric acid to 90 tons of the No. 2 stock-solution and this is brought to 27% H₂SO₄. This is the only point in the operation where acid is added to the solutions. When sufficient acid is not available for this, it is here that the reduction is made. Fair results can be obtained with 65 tons of solution at 15% H₂SO₄. The strong-acid solution is followed with 110 tons of No. 2 solution. The drain-valve is opened as soon as the top of the calcine has been covered with this

strong acid. As soon as this strong acid shows in the drainage the drain-valve is closed and aeration takes place. The air is applied underneath the false bottom, 16-lb. air being used. Some care is required in the application of the air. It is essential for good aeration that little or no solution should be underneath the cocoa-matting when the air is applied. The application of the air takes place intermittently from this point until the end of the leach. The washing of the charge is done with 300 tons of No. 1 wash-solution, followed by 300 tons of fresh hot water from the calcine-coolers.

The object of introducing the 50 tons of No. 2 solution before the strong-acid solution is put on, is to have it act as a piston protecting the copper-solution from this strong-acid solution. The idea is to get the bulk of the copper into the copper-solution, and to protect the copper-solution, which must go through iron for precipitating the copper, from getting strong acid mixed with it.

The 250 tons of No. 1 solution added becomes the strong-copper solution, which is as nearly acid-free as can be made. This is drained to the copper-solution storage-tank, from where it is drained to the precipitation launders. All of the No. 2 solution (50 + 90 + 110 tons) drains to the No. 1 solution-storage tank and becomes available as No. 1 solution for the next leach. The first 100 tons of the No. 1 wash-solution is drained to the No. 2 solution tank to make up for the solution discarded daily. The remaining 200 tons is drained to the wash-water drainage-tank. About 100 tons of the fresh water added finds its way into the system through the wash-water tank. What is available from the remaining 200 tons is drained directly to a separate precipitation launder, where this solution is discarded. The main idea in the disposal of solution is the conservation of NaCl, or its equivalent in chlorine, for further use.

Water is used to sluice out the tailing after leaching. A charge can be sluiced if necessary in about 6 hours, that is, from the time the first door is opened until the seventh door is closed and the tank is ready for calcine. The usual time, however, is about 8 hours. A screen analysis of tailing from the leaching-plant for July is here given:

Mesh	Opening mm.	Tailing	
		Solids %	Solids cum. %
14	1.18	4.51	4.51
20	0.833	12.98	17.49
28	0.589	18.99	36.48
35x	0.417	20.55	57.03
48	0.295	13.76	70.79
65	0.208	10.55	81.34
100	0.147	8.71	90.05
150	0.105	5.05	95.10
-150	4.90	100.0

A tabulation of the results which led to cutting down the volume of strong acid used and increasing the percentage of H₂SO₄ is also presented. On June 6, 1917, it was decided to try 138 tons of 20% H₂SO₄ in the odd-number tanks and 120 tons of 23% H₂SO₄ in the even-number tanks for one cycle.

On June 20 it was decided to increase the acid by 2% H_2SO_4 , that is, 90 tons at 27% H_2SO_4 . The results have justified the increase of strength in the acid used. If a smaller volume of solution could be used with any degree of certainty that it would reach all portions of the charge, about 75 tons at 27% H_2SO_4 would be sufficient. Considerable care in draining the solution is required to avoid channeling, thus preventing all the charge getting its share of this strong acid and salt solution.

PRECIPITATING. The copper-solution and wash-water drainage flow through concrete launders filled with iron for the precipitation of the copper. These solutions may be kept separate or be run together during their journey through the launders. About one-fourth of the copper-solution overflow is discarded, the other three-fourths being returned to the No. 2 solution tank. All the wash-water overflow from the launders is returned to the system. On leaving the iron launders the solutions are

mixed and returned through the same pump. When the returning solutions are entirely free from copper they are sent to the No. 1 wash-solution tank, and when a little copper is contained in the solution it is returned to the No. 2 solution tank. There is a total precipitating capacity of approximately 35,300 cu. ft., making roughly one and a half cubic feet per pound of copper precipitated daily. It requires only about 0.9 cu. ft. capacity to precipitate one pound of copper per 24 hours from a solution carrying 1.9 to 2.0% copper, while it requires over 3 cu. ft. for the wash-water running 0.25 to 0.30% copper to precipitate one pound of copper in the same time. The quantity of iron in one cubic foot of space is about 110 lb., that is, it averages this for the entire system.

The copper-solution contains CuSO_4 and CuCl_2 . The bulk of the copper is in the form of chloride. This probably accounts for the rapidity with which precipitation takes place, and also for the spongy nature of the cement copper. With ordinary care in cleaning the precipitating launders regularly the precipitation of the copper is absolute. Each launder is washed out once every four days with water. No copper whatever sticks to the iron, and the only reason it is ever necessary to remove the iron from the launder is to take out the accumulated copper and small pieces of iron from underneath the wooden racks. This is done at least once every two months on the first two launders that receive copper-solution. The iron is removed from the other 10 launders not more than once a year. The cement copper averages 65 to 70% copper and about 50 oz. silver per ton. The quantity of iron consumed per pound of copper produced is 1.05 lb. This figure is obtained from the actual weight of the iron used against the weight of copper produced over a period of 28 months. The figure obtained by determination of the iron in the copper-solution to the launders, and the iron in the copper-solution overflow from the launders, is 1.02 lb. of iron for each pound of copper precipitated.

RESULTS. The performance of the leaching-plant is given, as taken from the monthly metallurgical report for July 1917. The results for August show a higher recovery, but it is hardly representative, owing to the 'walk-out' on August 23, making it a short month.

Sand-tailing treated, tons.....	67,076.9
Copper in feed, per cent.....	0.72
Silver in feed, ounces per ton.....	0.54
Copper in tailing, per cent.....	0.13
Silver in tailing, ounces per ton.....	0.19
Sulphuric acid, pounds per ton (100% acid).....	50.79
Coal, per cent of feed.....	3.69
Salt, per cent of feed.....	1.23
Pounds of copper in feed.....	970,503
Pounds of copper recovered.....	720,801

The actual recovery of copper is 74.27%, while the theoretical, based on assays of heading and tailing, is 81.94%. This discrepancy is due partly to stack-loss and partly to the tailing obtained by the pipe sampler being higher in copper than indicated. The use of dirty water for sluicing allows only this one way for sampling. The

Hydraulic-Mining Debris in the Sierra Nevada

By G. K. GILBERT

*Hydraulic mining in the Sierra Nevada commenced in the early 'fifties and continued in the face of opposition from the residents of the Sacramento and San Joaquin valleys until 1884. A series of injunctions was obtained in that year, which, although it did not eliminate hydraulic mining, restricted it to such an extent that little has been done since. Some of the hydraulic mines discharged tailing directly into streams, others upon gentle slopes of the land. After checking mining operations the deposits in the mountain streams were gradually washed down-stream. Where the rivers left the mountain gorges and entered the great valley there was an abrupt reduction in slope and velocity, resulting in the deposition of debris. These deposits, which may be called Piedmont deposits, extended toward the valley from the foot of the range, and usually reached the mid-valley trunk-stream. The material was coarse near the mountains and finer farther west. At the same time, deposits were being made in the main trunk-streams of the valley, namely, the Sacramento and Feather rivers.

The quantity of debris that a given stream transports is its load; the quantity it can transport may be called its capacity. Capacity varies with slope. The greater the

slope the greater is the capacity. The change in capacity is always larger than the change in slope. Capacity varies with discharge. When the discharge is increased, the capacity per unit of discharge is also increased. An increase in discharge, however, does not increase capacity so much as the same relative increase in slope. Capacity varies with the character of the debris transported. The lower the specific gravity of the debris the greater the capacity, that is, the greater the weight of load which may be transported. The finer the debris the greater the capacity. Capacity is affected also by the shapes of the particles of debris, but, in general, only the size-factor is considered in relation to capacity. Size may be measured by diameter or by volume. In whichever way it is measured, an increase in fineness causes a somewhat greater increase in capacity. Capacity varies with the ratio of depth of water to width of stream. In the main, capacity increases with increase of this ratio, and this is true of the streams of Sacramento valley, but the opposite rule applies to small values of the ratio.

The fact that there is a limiting condition below which transportation does not take place is expressed by the word competent. For a stream of given discharge, flowing in a given channel and carrying debris of a given fineness, there is a competent slope; in a channel of given form and slope, and with debris of given fineness, there

*Abstract: Professional Paper No. 105, U. S. Geological Survey.

is a competent discharge; and for a given discharge in a given channel there is a competent fineness. The ratio in which capacity is modified by a change in slope, discharge, fineness of debris, or depth of current, is greater when the conditions are near competence than when they are far above competence. In other words, capacity is most sensitive, when near its lower limits, to changes in the conditions that control it.

The laws have been experimentally determined for the bed-load† treated by itself, and they are believed to be approximately true for the suspended load by itself. Nevertheless they cannot be affirmed for the total load, because of complications caused by the shifting of material from one load to the other. If a stream that is loaded to its full capacity reaches a point where the slope becomes smaller, it becomes overloaded. Part of the load is dropped, making a deposit. If a fully loaded stream reaches a point where the slope becomes steeper, its enlarged capacity causes it to take more load, and the taking of load erodes the bed. If the slope of the stream is not adjusted to the discharge and to the load it has to carry, then the stream continues to erode or deposit, or both, until adjustment has been effected and the slope has become just adequate for the work. Any change of conditions which destroys the adjustment between slope, discharge, fineness, and load, makes re-adjustment necessary and starts a series of changes which may extend to all parts of the stream-profile. The mining debris disturbs the adjustment of the streams by adding to their load. Reclamation by levees disturbs it by increasing the flood-discharge in parts of the river-channels.

The law of adjusted profiles applies to streams with mobile beds, that is, alluvial streams. Streams with fixed beds are normally under-loaded, and their beds are modified only by abrasion. This process works toward an adjustment of slopes, but very slowly, and the factors involved are different from those of alluvial streams. The channel of an alluvial stream is composed of alternating ponds and shoals. The dimensions of these are related to the discharge. The variable discharge modifies these continually, each particular discharge tending to adjust them to its needs. Because of the greater power of streams during flood, the pattern of the bed is most nearly adjusted to flood-conditions. An alluvial stream that is not confined by rigid banks shapes for itself a course made of curves. The curves are not stationary, but undergo continual changes. The curve-pattern is large for a large stream and small for a small one. In a variable stream the pattern is adjusted to the needs of the flood-discharge. The general slope of a stream-bed is determined chiefly by the load that travels at the time of the larger floods.

The laws thus far stated apply to the transportation of debris along a bed composed of similar debris. When a stream is made to sweep debris along the unyielding bed of a sluice or flume other laws apply. Capacity is

greater for smooth beds than for rough. It is greater for coarse debris (up to the limit of competence) than for fine. In general it is greater for a flume than for a natural stream of the same size.

The amount of debris that has been removed since hydraulic mining practically ceased is indicated by the following: At the 'Narrows' of the Yuba river, several miles above Marysville, is a gauging-station of the U. S. Geological Survey. In 1903 a discharge of 500 second-feet corresponded to a gauge-reading of 13.6 ft. In 1913 the gauge-reading for the same discharge was 4 ft. At Sacramento, the records show low-water readings of zero in the city gauge in 1849 and 1856. In the early 'nineties, the low-water readings averaged about 10 ft., while in 1913 the low-water reading was 3 ft. In 1849 the tidal range at Sacramento was about 3 ft. This disappeared entirely about 1880, but re-appeared when the river again began to scour. In 1913 the tidal range was 1.5 ft. Estimates have been made of the amount of debris deposited in Suisun, San Pablo, and San Francisco bays, and in Carquinez strait, based on soundings by the U. S. Coast and Geodetic Survey. In Suisun bay, 64,000,000 cu. yd. was deposited between 1867 and 1886; in Carquinez strait, 40,000,000 cu. yd. between 1861 and 1890; in San Pablo bay, 366,000,000 cu. yd. between 1857 and 1897; and in San Francisco bay, 196,000,000 cu. yd. was deposited between 1856 and 1896. The total estimated amounts for the period 1849-1914 are as follows: Suisun bay, 200,000,000 cu. yd.; Carquinez strait, 50,000,000 cu. yd.; San Pablo bay, 570,000,000 cu. yd.; San Francisco bay, 326,000,000 cu. yd. making a total of 1,146,000,000 cu. yd. Approximate surveys were also made in 1909 to determine the amount of material removed in mining between 1849 and that year. These amounts are given below. The quantity removed since that time is comparatively small, probably between 5,000,000 and 10,000,000 cubic yards.

Hydraulic mining:	Cubic yards
Upper Feather river.....	100,000,000
Yuba river	684,000,000
Bear river	254,000,000
American river	257,000,000
Streams tributary to lateral basins of Sacramento river	30,000,000
Mokelumne to Tuolumne river, inclusive....	230,000,000
Placer mining	60,000,000
Quartz mining (one-fourth in Sacramento basin)...	50,000,000
Drift-mining (three-fourths in Sacramento basin)	30,000,000
Total mining debris:	
From hydraulic mining.....	1,555,000,000
From all mining tributary to Sacramento river	1,390,000,000
From all mining tributary to Suisun bay.....	1,665,000,000

The last-named amount is nearly eight times the material moved in constructing the Panama Canal.

In addition to mining, other causes have contributed to the erosion. Cultivation can be practised so as to reduce erosion instead of increasing it, but such methods are not usual in the Sierra Nevada. Roads and trails on steep grades and the side-ditches dug to protect roads,

†U. S. Geological Survey Professional Paper 86, 1914.

all assist erosion. So also does over-grazing. In addition there is considerable 'natural' erosion. The total 'non-mining' debris removed from the land surface of the various water-sheds tributary to Suisun bay between 1849 and 1914 is estimated at 700,000,000 cu. yd., of which 420,000,000 is from the watershed of the Sacramento river. If the mining debris is added, allowance being made for what has been removed since 1909, the total for the watersheds tributary to Suisun bay is 2,375,000,000 cu. yd., of which 1,820,000,000 cu. yd. is credited to the Sacramento river watershed.

flood-control works will hasten the scouring of the main river-channels that is now in progress, and the debris now in the river-channels will be deposited in the bays. Of the 625,000,000 cu. yd. of mountain deposits of debris, 100,000,000 cu. yd. will probably remain in the mountains. Of the 520,000,000 cu. yd. of Piedmont deposits, 335,000,000 cu. yd. will probably be permanent. This leaves 350,000,000 cu. yd. to be carried to the bays. Assuming 50 years as the time when the amount of mining debris moved will have become negligible, and that 8,000,000 cu. yd. per year is the annual loss from erosion

PIEDMONT DEPOSIT OF THE YUBA SHOWING DEBRIS PLAIN NEAR ITS BROADEST PART

Surveys indicate that at the present time this amount is distributed approximately as follows:

	Cubic yards
Deposited within the mountains.....	265,000,000
Piedmont deposits	520,000,000
Deposits in the channels of valley rivers.....	100,000,000
Deposits on inundated lands, including tidal marshes	294,000,000
Deposits in the bays.....	1,146,000,000
Deposits in the ocean.....	50,000,000
Total	2,375,000,000

This estimate of the mining debris does not include the material that is being and will continue to be washed by natural agencies from the slopes of abandoned hydraulic-mine workings.

Future movement and re-adjustment of the deposits of debris will be affected by restraining-works on rivers such as have already been built on the Yuba river at Daguerre point, but more especially by the work for flood-control now being done on the valley streams. In a few years a system of by-passes and levees will be completed, cutting off the basins that used to receive a large proportion of the debris carried by the rivers. These

from natural causes, then the non-mining debris to be carried by the rivers in that time will be 400,000,000 cu. yd. Adding the amount now in the rivers, and the 350,000,000 cu. yd. of mountain and Piedmont deposits, gives 850,000,000 cu. yd. Two-thirds of the mountain and Piedmont deposits is coarser than silt, and the river deposits are almost entirely sand. Seven-eighths of the soil-waste is silt. However, in being carried to the bays, nearly all the material will be so comminuted before it comes to rest that it will be exceedingly fine. Of the total amount, it is estimated that 50,000,000 cu. yd. will be deposited on the inundated lands before the reclamation projects now under way are completed, 40,000,000 cu. yd. will be carried to the ocean, and the remaining 760,000,000 cu. yd. will be deposited on the various shoals in the bays. In other words, the amount of debris now deposited on the shoals will be increased about 67%. A continuous channel exists from the mouths of the Sacramento and San Joaquin rivers to the Golden Gate bar. This channel is maintained by tidal currents. The tides are such that the stronger ebb-currents have a higher velocity than the stronger flood-currents. The ebb-currents, moreover, are reinforced by the discharge from

the rivers. Consequently, sand and other coarse debris delivered to Suisun bay by the rivers, and dragged forward and backward by the currents, has a net movement toward the bar. While thus in transit it suffers attrition, and the greater part is ground so fine as to leave the channel-bed and to pass into suspension. At Pinole shoal, in San Pablo bay, midway between the river mouths and the bar, the coarsest material in the bed of the channel is fine sand, the grains being about as large as those of the sand which constitutes the crest of the bar. The course of the river-sand has not been traced beyond this point, but little of it can survive the buffetings of the remaining journey and find lodgment on the bar. The sand on the bar is stirred by storm-waves, which agitate the water to considerable depths, and it also is worn to silt.

The depth of water on the bar depends not only on the rate at which sand is supplied to it but also on the strength of tidal currents. The strength of currents depends in turn on the volume of the tidal prism. The effective tidal prism is the space between the position of the water-surface in the bays when the outward flow begins at the Golden Gate and the position of the water-surface when the outward flow ends. The volume of the prism has been reduced and is being reduced in three ways: by the filling of shoals and construction of piers, by the reclamation of tidal marshes, and by the deposition on shoals in the bays of debris brought by rivers and creeks. The encroachment caused by mining debris and general soil waste has reduced the tidal prism 2 or 3%, and the encroachment from marsh-reclamation about 1.5%. Theoretically the reduction of the tidal prism should produce two changes in the bar: a migration of the crest toward the land, and an upward growth, reducing the depth of water on the crest. A comparison of charts made from surveys in 1855, 1873, and 1900 shows that in each interval between surveys the crest migrated toward the land, the entire change of position being 1000 ft. The same charts indicate a loss in depth of 6 in. between 1855 and 1873, and a gain of 1 ft. between 1873 and 1900, giving a net gain of 6 in. between 1855 and 1900, but the accuracy of these indications is questioned. The theoretic change in depth corresponding to a migration of 1000 ft. would be less than 6 in., and would be a loss instead of a gain.

A reduction of the supply of sand is theoretically sufficient to increase the depth of water on the bar, and at the same time to cause the crest to move toward the shore, but there is no independent evidence of deficient sand-supply during the period to which the survey-data pertain. The observed gain in depth may have been actual, the result of an unknown change in conditions determining sand-supply, or may have been apparent only, the result of some undiscovered defect in methods of survey.

There is no reason to believe that mining debris deposited on the bar has affected or might affect the depth of water on the bar to any appreciable extent. There is good reason to believe that mining debris and the soil-

waste promoted by agriculture and other industries have reduced and will reduce the depth of water by reducing the strength of the tidal currents, their effects in this direction being combined with the similar effects of reclaiming tidal marshes on the borders of the bays. Encroachments on the tidal prism of Suisun bay have less influence on the currents in the Golden Gate than similar encroachments in the lower bays. The reclamation of marsh-lands adjoining Suisun bay and Napa river has about half as much influence on the Golden Gate currents as the reclamation of marsh lands adjoining the southern part of San Francisco bay. The currents are affected only slightly by the reclamation of marsh-lands of the river-deltas; reclamation near the river mouths tends to weaken the currents, and reclamation in the remoter parts of the deltas to strengthen them.

Phosphate in Egypt

By E. CORTESE

*Phosphate occurs in many places in Upper Egypt, along the Nile Valley, principally on the right side, and also near the Red Sea coast. Upon rocks like granite, serpentine, porphyry, and diabase comes the Cretaceous formation, containing considerable quantities of phosphate, at Gebel Duwi, Gebel Nakheil, and Gebel Koseir El Kadim, not far from the coast. More to the north, in the hills near Safaga bay, is another rich bed. Phosphate is said to exist near Suez and in the Sinai peninsula. The formation in Egypt is variable, not only from place to place, but even within small areas. The mines are well developed on the right bank of the Nile at Sharawna and along the Red Sea coast, at Safaga and near Koseir. The uppermost bed of the Sharawna formation is a hard limestone, 1½ to 4 ft. thick, made up entirely of oyster shells, strongly cemented by carbonate of lime. In places this changes into a true phosphatic bed; the oyster shells disappear little by little, the rock becomes softer, granulated, and in less than 1000 ft. the hard bed is transformed into fine tricalcic phosphate, assaying as high as 63%. Occasionally, the phosphate, instead of replacing the oyster bed, spreads underneath and reaches a thickness of 2.3 ft. and a percentage of 60; in other places it is 6½ ft. or more, is very hard, full of small coprolites, but is not above 25 to 35%.

The Sabaieh phosphate is already on the market, raw or ground. In parts of the desert it is estimated that there are 50 million tons of phosphate. Immense quantities of relatively low-grade material are available.

PLATINUM was discovered in the ore at the Boss mine, Clark county, Nevada, in 1914. The discovery attracted wide attention, and, according to Fred. A. Hale Jr., the production of that metal promises to become of prime importance to the district.

Minerals Separation v. Butte & Superior

PART OF BRIEF FOR DEFENDANT

This is an appeal from the decision of the District Court sustaining Letters Patent No. 835,120 for Process of Ore Concentration, issued to Sulman, Picard & Ballot, on November 6, 1906, and finding the same to be infringed by the defendant, not only when it has used less than 1% of oil on the ore, but also when it has used more than 1% of oil on the ore.

Prior to January, 1917, the defendant used "oils" (among others oleic acid) in quantities below one-half of 1% on the ore. Since that date it has not used oleic acid at all, but has used other "oils" in quantities always above one-half of 1% on the ore, and for most of the time in quantities above 1% on the ore.

The court below found that prior to January, 1917, defendant infringed all the claims in issue (to wit, claims 1, 2, 3, 5, 6, 7, 9, 10, 11, 12), and that since that date it has infringed all said claims excepting claims 5, 6, and 7, which specifically relate to the use of oleic acid.

The facts presented require this Court to decide not only whether the use of more than 1% of oil infringes the patent in suit, but also whether the use of more than one-half of 1% and less than 1% of oil infringes. Thus, referring to Defendant's Exhibit No. 158, it will be seen that defendant used during the period from January 17 to 29, 1917, 0.84% of oil, and during the period from January 30 to February 3, 1917, 0.80% of oil. So also Defendant's Exhibit No. 161 shows that between February 1 and 9 the amounts of oil used daily were between 0.64% and 0.79%. Subsequently more than 1% of oil on the ore was used by defendant, as shown by said exhibits and Exhibit No. 162. The question whether the use of either of these quantities of oil constituted an infringement of plaintiffs' patent is, therefore, directly presented.

We admit that, under the authoritative and final interpretation of the patent by the Supreme Court, the use of oil in quantities of less than one-half of 1% infringed; but we contend that, under said interpretation, the use of oil in quantities above one-half of 1% does not infringe.

The patent in suit is the same patent which was before the courts in the Hyde case. In that case the learned Judge of the District of Montana *did not regard the use of a fraction of 1% of oil as of the essence of the patented process*. He therefore sustained not only the claims in issue which were in terms limited to the use of a fraction of 1% of oil (to wit, claims 1, 2, 3, 5, 6, 7, 12), but he also sustained the claims which were in terms broad enough to cover the use of any "small quantity" of oil (to wit, claims 9, 10, 11).

When the Hyde case came before this Court on appeal, an entirely different view of the invention was taken.

This Court found that the *essence of the invention consists in the use of a small fraction of 1% of oil*. In its opinion it said:

"That which is presented as *new* in the patent, and as the *pivotal discovery on which its validity depends*, is the formation of a froth or scum containing the metaliferous matter produced by agitation of the pulverized ore in water, by the action of oil in a *quantity less than one per cent of the quantity of ore treated*."

Again:

"When the claims and the description of the process of the appellees' patent are compared with the patents of the prior art, it will be seen that the *only material difference is in the smaller quantity of oil which the appellees use*."

This court also held, as a matter of law, that the reduction in the amount of oil used to a fraction of 1% did not involve patentable subject-matter. It, therefore, remanded the case with directions to dismiss the bill.

Next, the patent in suit came before the learned Judge of the District of Delaware in the Miami case. In that case the court found, just as this court had before found, that the *essence of the invention consists in the use of a small fraction of 1% of oil*. In its opinion it said:

"The patentability of the process of the first patent in suit *resides in the use of oil in the extremely minute proportion disclosed in the descriptive portion of the patent to effect separation of froth with its metallic particles from the remainder of the mixture by flotation*. The amount there disclosed is *not in excess of 'a fraction of one per cent on the ore' and may be only one-tenth of one per cent on the ore, or even less*."

The learned District Judge in the Miami case, however, held, as a matter of law, that the use of a small fraction of 1% of oil constituted patentable subject-matter. He therefore sustained those claims in issue there which are in terms limited to a fraction of 1% of oil (to wit, claims 1 and 12), while he held *invalid the claim in issue there which is in terms broad enough to cover the use of any "small quantity" of oil (to wit, claim 9)*.*

Subsequently, the Hyde case came before the Supreme Court by *certiorari*. The Supreme Court agreed with this court, and with the District Judge in the Miami case, in finding that the *use of a fraction of 1% of oil is of the essence of the invention*. It said:

"The process of the patent in suit, as described and practiced, *consists in the use of an amount of oil which is 'critical,' and minute as compared with the amount used in the prior processes, 'amounting to a fraction of one per cent on the ore.'*"

*Claims 10 and 11 were not put in issue in the Miami case.

Again:

"While the evidence in the case makes it clear that they discovered the final step which converted experiment into solution, 'turned failure into success,' yet the investigations preceding were so informing that this final step was not a long one, and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions' amounting to a fraction of one per cent."

While the Supreme Court held, as a matter of law, that the use of a small fraction of 1% of oil constituted patentable subject-matter, it specifically condemned the view taken by the District Judge in the Hyde case that the use of a small fraction of 1% is not of the essence of the invention. It said:

"While we thus find in favor of the validity of the patent, we cannot agree with the District Court in regarding it valid as to all of the claims in suit."

It, therefore, declared invalid those claims which in terms are broad enough to cover the use of any "small quantity" of oil (to wit: claims 9, 10, and 11) and sustained only those claims which are in terms limited to the use of a "fraction of 1% of oil."

Subsequently, the Miami case came before the Circuit Court of Appeals for the Third Circuit. Since the questions of validity and scope of the patent in suit at that time had been authoritatively determined by the Supreme Court, the only questions considered were (1) the scope of the patent as determined by the Supreme Court, and (2) infringement. As to infringement, the decision of the court was not unanimous; but as to the fact that the Supreme Court had strictly limited the patent to the use of a fraction of 1% of oil, it was entirely unanimous. Discussing the contention of plaintiff in that case, that: "Whenever the modifying agent of the patent (oil) is used, a person infringes who gets air in the pulp in any fashion and agitates the mixture by any means to a sufficient extent to cause the mineral particles to attach themselves to air bubbles, and to rise therewith above the top of the mixture in a collection of bubbles and metal particles, to wit, froth," the court said:

"The contention of the plaintiff, at least, omits the very definite limitation of the patent to the results obtained by the use of oil within the described proportions."

Again it said, referring to the Supreme Court's decision:

"The District Court had held valid certain claims in which the proportion of oil was described simply as 'a small quantity,' and the Supreme Court, in reversing that finding and holding those claims invalid, used the quoted words of limitation in confining the patent to the results obtained by the use of oil in the critical proportions of less than 1%."

Further on in its opinion it said:

"The affinity of oil for metal was known, and, though old, was employed in the invention; but that this affinity in a given condition is greatest when its quantity is rela-

tively least, or that the affinity increases with the decrease of oil below a given quantity (less than 1%), is the soul of the discovery and was wholly new."

We, therefore, see that, in succession, this court in the Hyde case, the District Court of Delaware in the Miami case, the Supreme Court in the Hyde case and the Court of Appeals of the Third Circuit in the Miami case, all agreed in holding—and in so holding they all disagreed with the District Court of Montana—that the use of a fraction of 1% of oil is of the essence of the patented process; and that the use of larger quantities of oil are not, and cannot be covered by the claims of the patent in suit.

As we read the decision below in this case, it seems to us that the learned District Judge has overlooked these facts. It seems to us that he has overlooked the fact that the Supreme Court did not agree with him in finding that the patentees are entitled to cover the use of any "small quantity" of oil; but, on the contrary, that the Supreme Court agreed with this Court in finding that the use of a small fraction of 1% of oil is of the essence of the patented process. The opinion of the District Court in this case, holding that the use by defendant of 1% and more of oil infringes, seems to us to be a reaffirmance in all respects of its decision in the Hyde case, including the errors in it which have been condemned by the Supreme Court.

THE QUESTIONS TO BE DECIDED

Since the Supreme Court has in the Hyde case authoritatively determined the rights of the plaintiffs under the patent in suit, this court at this time has only three questions to decide:

The first question is: What has the Supreme Court decided in the Hyde case as to the metes and bounds of the invention at bar, and does the use of oil in proportions greater than the so-called "critical proportions" trespass upon any just rights of the plaintiffs, as those rights have been defined by the Supreme Court?

The second question is: Is the new evidence presented in this case—evidence not before the Supreme Court in the Hyde case—of such character as, in the opinion of this court, would have led the Supreme Court to reach a different conclusion if it had been presented in the Hyde case?

The third question is: What is the purpose and effect of the so-called "disclaimer" filed by the plaintiffs after the opinion of the Supreme Court in the Hyde case was handed down?

I

The first question requires this court only to study and apply the decision of the Supreme Court. Whether we or our adversaries think it right or wrong, that decision is the law of the land with respect to the patent in suit, on the facts presented in the Hyde case. No court, except the Supreme Court itself, can change it.

This court will not listen to the defendant if it argues that the Supreme Court was wrong in finding invention

in the patent in suit on the record before it; and for the same reason, this court will not listen to the plaintiffs when they argue, as they do argue in this case, that the Supreme Court was wrong in limiting, as it certainly did limit, the scope of the patent in suit to the use of a small fraction of 1% of oil on the ore.

Defendant does not at this time, and in this place, quarrel with the decision of the Supreme Court in the Hyde case. It is the plaintiffs who quarrel with that decision.

In its decision the Supreme Court said:

"The process of the patent in suit, as described and practiced, consists in the use of an amount of oil which is 'critical,' and minute as compared with the amount used in prior processes. 'amounting to a fraction of one per cent on the ore.'"

"The experimenters were working on the Cattermole 'Metal-Sinking Process' as a basis when it was discovered that the granulation on which the process depended practically ceased when the oleic acid (oil) was reduced to about five-tenths of 1% 'on the ore.' It was observed, however, that, as the amount of oleic acid was further reduced and the granulation diminished, there was an increase in the amount of 'float froth,' which collected on the surface of the mass and that the production of this froth reached its maximum when about one-tenth of one per cent or slightly less 'on the ore' of oleic acid was used.

"While we thus find in favor of the validity of the patent, we cannot agree with the District Court in regarding it valid as to all of the claims in suit. As we have pointed out in this opinion, there were many investigators at work in this field to which the process in suit relates when the patentees came into it, and it was well engaged in study of prior kindred processes that their discovery was made. While the evidence in this case makes it clear that they discovered the final step which converted experiment into solution, 'turned failure into success,' yet the investigations preceding were so informing that this final step was not a long one, and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions,' 'amounting to a fraction of one per cent on the ore,' and therefore the decree of this court will be that the patent is valid as to claims No. 1, 2, 3, 5, 6, 7, and 12, and that the defendant infringed these claims, but that it is invalid as to claims 9, 10, and 11."

Comparing the group of claims which was sustained with the group of claims which was condemned, we find that all the claims of both groups were limited in terms to the production of a "froth" by "agitation," and to the separation of the "froth" from the material; but that the claims which were sustained were limited in terms to the use of oil in proportions of less than 1% of the ore, while the claims which were condemned were broad enough to cover the use of a "small quantity" of oil.

The only difference between the claims which were sustained and those which were condemned is, therefore, that the former were, while the latter were not, in terms limited to the use of less than 1% of oil on the ore. Nothing can be plainer, therefore, than that the Supreme Court has decided that the plaintiffs are entitled to a monopoly of the use of oil in the critical proportions described in the specifications and in the proofs in the Hyde case, but that they are not entitled to a monopoly of the use of any larger quantities of oil.

The only question which can arise in construing the decision of the Supreme Court is whether the use of oil in proportions between one-half of one per cent (0.5%) and one per cent (1%) falls within the monopoly of the patent. The Supreme Court says, in the passage above quoted, that the "patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims as 'critical proportions' 'amounting to a fraction of one per cent on the ore.' " The questions which arise are: What "fraction of one per cent" is here referred to? What "fraction of one per cent" is "often described in the testimony" in the Hyde case as the critical proportions? What "fraction of one per cent" is referred to in the claims as the critical proportions? To answer these questions this court must go to the patent specifications, and to the testimony which was before the Supreme Court to which it referred. It must first ascertain, therefore, what are the "critical proportions" set forth in the patent in suit.

THE CRITICAL PROPORTIONS DESCRIBED IN THE PATENT ARE ONE-HALF OF 1% OR LESS

In the introductory clause the patent refers to the Cattermole process, in which it says "an amount of oil varying from four per cent to six per cent of the weight of the metalliferous matter present" is employed. Simple arithmetic teaches us that 4% of the weight of the metalliferous matter in any ore which assays 25% metalliferous matter would be 1% on the ore (and an assay-value of 20% is exceptional, so that 4% on the weight of the metalliferous matter in all ores assaying less than 25% would be "a fraction of one per cent" on the ore.*

The specification continues:

"We have found that if the proportion of oily substance be considerably reduced—say to a fraction of one per cent on the ore—" etc.

The specifications say, in the example given beginning at page 1, line 70, that:

"To this is added a very small proportion of oleic acid (say from 0.02 per cent to 0.5 per cent on the weight of ore)."

Again they say, page 1, line 96:

"The minimum amount of oleic acid which can be used to effect the flotation of the mineral in the form of froth

*Plaintiff's expert in the Hyde case, Dr. Chandler, admitted that the Cattermole oil proportions applied to the tailing at the Broken Hill mine where the process was practiced, called for the use of only 1.2 to 1.8% on the ore.

may be under 0.1 per cent of the ore; but this proportion has been found suitable and economical."

We, therefore, see that the "critical proportions" referred to by the Supreme Court are defined in the examples contained in the specifications as being between one-half of one per cent (0.5%) and one-fiftieth of one per cent (0.02%), the preferred amount specified being one-tenth of one per cent (0.1%).

THE CRITICAL PROPORTIONS "OFTEN DESCRIBED IN THE TESTIMONY" IN THE HYDE CASE ARE LESS THAN ONE-HALF OF ONE PER CENT

Turning now to the record in the Hyde case, we find that the testimony referred to by the Supreme Court as defining the "critical proportions," to which the patent has been by it limited, is as follows:

In 'Complainant's Exhibit Higgins' Report of March 16, 1905' the following appears:

DETAILS OF EXPERIMENTS.

Acid.	Oleic Acid.	% of Oleic	% on ore	Time	Temp.	Remarks
1.1%	15 cc.	3		4 min.	30.5° C.	Very little float.
"	7½ cc.	1.5	"	4½ "	31 "	Rather more float.
"	5.2 cc.	1.04	"	6 "	31 "	Still more float.
"	3.1 cc.	0.62	"	6 "	32 "	
"	1.6 cc.	0.32	"	7 "	31 "	Float vastly increased.
"	0.5 cc.	0.10	"	8 "	31 "	Float vastly increased.
"	0.5 cc.	0.1	"	4½ "	29 "	Not finished.
"	0.4 cc.	0.8	"	6½ "	30.5 "	
"	0.5 cc.	0.1	"	8 "	31 "	
"	0.5 cc.	0.1	"	8 "	31 "	Weight of cones. 170 gms.
"	0.2 cc.	0.04	"	8 "	32 "	Apparently not much different.
"	0.1 cc.	0.0025	"	12 "	32 "	Little worse.
"	none	none	"	7 "	32 "	Very little float.
"	none	none	"	10 "	32 "	More froth.

Plaintiff's witness Dr. Chandler said:

"The inventors simply state, referring to the Cattermole patent which has just been previously discussed, that four to six per cent of the weight of metalliferous matter present is employed, that they have found that if the proportion of oily substance be considerably reduced, say to a fraction of one per cent on the ore, granulation ceases to take place. What this fraction of one per cent is, they do not mention. *The only way in which I can interpret this fraction of one per cent is by referring to other portions of the specification, where this fraction of one per cent is expressed in figures; for example, at line 81 of page 1 of the specification is the following statement, speaking of the ore:*

"To this is added a very small proportion of oleic acid (say from 0.02 per cent to 0.5 per cent on the weight of the ore)."

"That is, from 1/50 of one per cent up to one-half of one per cent."

Again, he said:

"These extremes represent from 0.4 of a pound per ton of ore to 10 pounds per ton of ore. The patentees do not state on what particular condition of the ore this variation of quantity depends, whether it depends upon the

percentage of zinc in the ore or some other quality, but they do indicate that the selection of quantity *between these extremes* must rest with the person familiar with the art who practices the process and it is fair to assume that such person would decide how much oleic acid to use by the results of the simple preliminary tests suggested by the patentees."

Plaintiffs' witness Ballantyne testified as follows:

"I have seen the agitation-froth process carried out many hundreds of times. I have also seen investigations of the process making wide variations step by step in the factors which I have referred to above, and I have myself, on many occasions, carried out these investigations and I now know that if the instructions which Messrs. Sulman, Picard, and Ballot drew up in February, 1905, are carried out, namely, to use a slimy pulp, acidified with say 0.5% of sulphuric acid, to heat the pulp say to 30° C. and then to agitate it violently with proportions of oil beginning at 50 lb. of oil per ton of ore and repeating this test, reducing the quantity of oil step by step down to the *vanishing point*, it is inevitable that the agitation-froth shall be produced when the *quantity of oil is diminished to the limits set forth in the patent in suit*, and that a particularly good froth and efficient concentration is obtained when the proportion of oil is about 0.1% on the ore, the percentage recommended in the patent in suit as being suitable and economical."

In answer he said:

"In my opinion the operation of the agitation-froth process is defined in the *clearest possible terms in the patent in suit*, and this remark applies particularly to the *quantity of oil to be used*."

Further along in the same answer he said:

"I have never seen the agitation-froth process successfully carried out by the use of an amount of oil equal to practically one per cent by weight on the ore, and in my opinion 0.9999% of oil would not be a proper quantity (that is to say, it would not be a suitable and economical quantity), as contemplated by the patent, and would not therefore be a suitable fraction of one per cent as contemplated by the patent."

Ballot, one of the patentees of the patent in suit, said:

"The only way to carry out the process is that of applying the proportions of oil set forth in the patent, but to determine, as all practical men will do, which of the proportions, *within the range*, yield the best result, the characteristic nature of the froth is always an indicator which will of itself tell an experienced operator when the best conditions have been attained. * * *"

Sulman, one of the patentees of the patent in suit, examined as a witness for defendant, said:

"When we decreased the amount of oil to about 0.6% upon the ore, granulation had ceased to appear and a very considerable proportion of mineral was found to float to the surface as a thick froth. We still further decreased the amount of oil until we found that with 0.2 to 0.1% of oil on the ore *practically the whole of the mineral came to the surface as a thick blackish matted froth*."

Picard, one of the patentees of the patent in suit, testified as follows:

"Q. 9. In the patent in suit, No. 835,120, in an example of the application of the process the amount of oleic acid used in that instance is specified as from 0.02 to 0.5% on the weight of ore, the latter quantity being twenty-five times the former. How would an operator practicing the process determine between these wide limits what quantity of oil to use?

"A. As a matter of fact, *both quantities mentioned are so minute* in relation to the proportion of ore that it is *hardly right to describe the limits as very wide*, but the operator would have no difficulty in determining, if there was any marked difference, which was the best quantity to use, by simply noting whether he was obtaining the specific frothing phenomenon which the patent indicates as being that required."

Ballot testified as follows:

"Q. 34. And when you saw the work in progress from March 1, 1905, onward, as referred to by you in your answer to question 29, was this the first occasion upon which you had been informed as to the use in an oil flotation process of the intentional heating in of air for the purpose of promoting flotation?

"A. The intentional heating in of air to produce or promote the flotation of froth which was developed by that process was certainly not known until the fact had been actually discovered that by using a *very small quantity of oil, say 0.2 or 0.1%, and agitating it for a certain time, and then leaving the mixture to stand that the whole froth rose to the surface.* * * *"

Higgins, one of plaintiffs' engineers, examined as a witness by defendant, stated, as his testimony was put in narrative form in the Supreme Court transcript, in answer to a question as to what was the "first occasion upon which you ever saw a part of the constituents of the ore, which, in the form of pulp had been oiled, floating upon the surface of the pulp" that:

"In all the slide machine tests that I have conducted I have *never had to use quantities of oily reagents outside of those mentioned in the patent in suit.* The greatest amount of oil that I have ever used in practice is *four pounds per ton of ore*, and the smallest amount I have ever used in practice is *one pound of oil per ton of ore.*"

Plaintiffs' witness, Dr. Liebmann, testified as follows:

"They inform the world what they consider the limits of their proportions, and they add that in their experience 0.1% of oil of the amount of ore has been found 'suitable and economical.' Surely one cannot demand more, and even a metallurgist of very low qualifications cannot fail to determine with the greatest ease what quantities will give him the desired results."

The foregoing is the testimony to which the Supreme Court refers in its opinion, where it says "the patent must be confined to the results obtained by the use of oil within the proportions *often described in the testimony* * * * as '*critical proportions.*'"

What were the "critical proportions" "often described

in the testimony" to which the Supreme Court has in terms limited the patent in suit? The answer is: They were less than one-half of one per cent (0.5%) of oil on the ore. It is to these proportions that the Supreme Court has limited the patent in suit. In other words, the "fraction of one per cent" of the claims is *that fraction of one per cent which is half of one per cent (0.5%) or less.* Any quantity of oil greater than one-half of one per cent (0.5%) on the ore is not within the scope of the patent as construed by the Supreme Court.

This construction of the patent was not only justified by the testimony in the case, but it was directly invited by plaintiffs' counsel in argument.

Plaintiffs' counsel, Mr. Kenyon, in reply to questions put by Mr. Justice McREYNOLDS and Mr. Justice PITNEY, said:

"MR. JUSTICE McREYNOLDS: I would like to ask you when in this process of reducing oil your invention came into existence?

"MR. KENYON: At *about one-half of one per cent* of oil.

"MR. JUSTICE McREYNOLDS: Before you got to the one-half of one per cent did you have any invention?

"MR. KENYON: We were passing from the region of Cattermole, which was a distinct—

"MR. JUSTICE McREYNOLDS: *I want to know when your invention came into existence?*

"MR. KENYON: This invention was *not reached*, I should say, from those figures, until *about 0.5, that is, one-half of one per cent, of oil was reached.*

"MR. JUSTICE McREYNOLDS: At one per cent you had no invention?

"MR. KENYON: *No.*

"MR. JUSTICE McREYNOLDS: At one-half of one per cent you did have invention?

"MR. KENYON: *It began to come. Remote, but it began to come. At 0.3 of one per cent the float vastly increased. At 0.1 of one per cent the float again vastly increased.*

"MR. JUSTICE McREYNOLDS: WHEN THIS FLOAT HAS MORE THAN ONE-HALF OF ONE PER CENT OF OIL IT DOES NOT INFRINGE?

"MR. KENYON: IT DOES NOT INFRINGE.

"MR. JUSTICE PITNEY: What have you to say in answer to what Mr. Scott said the other day to the effect that 1.8%, or perhaps more, of oil, would give the same result with increased agitation.

"MR. WILLIAMS: *Absolutely no.*

"MR. KENYON: *It would not.*

"MR. JUSTICE PITNEY: I understood him to say so yesterday, and I supposed there was something in the record to justify it.

"MR. KENYON: *Nothing.* That will be a part of my argument."

Mr. Kenyon said in his oral argument in this case before the District Court that nothing was further from his intention in his answers to Mr. Justice McREYNOLDS' inquiries than to limit the claims to one-half of 1% of oil.

In view of the proofs we do not see how he could have answered Mr. Justice McREYNOLDS otherwise. But Mr. Kenyon's *intentions* are immaterial. The simple question here is: what were the facts and arguments presented to the Supreme Court as a basis for the decision reached?

He also said:

"It is apparent now that the inventors in their minute one-tenth of one per cent oil frothing reagent were really invoking a characteristic and a power of oil in an ore concentration process that *develops only in that relatively microscopic quantity*, and which is defeated and disappears when that minute quantity is even *slightly* exceeded, a characteristic and a power of oil which had not existed in the prior oil concentration processes of the art, which had never been utilized by anybody for ore concentration, and the very existence of which had not been known or suspected."

Complainant's counsel, Mr. Williams, in his argument before the Supreme Court said:

"The amount of oil that we use is generally one-tenth of one per cent on the ore; two pounds of oil to the short ton of ore. Every ore presents its own problem, but for a given ore and a given oil there is a certain *critical* factor. The variations in that factor in practice have been from a *trifle less than one pound of oil to the long ton in the case of the rich ores of Australia to four pounds of oil to the long ton in the case of a lean copper ore at the Braden mines in Chile*. Those are the variations of different oils and different ores, and because of those *minute variations* you have the impossibility of saying that this process always uses just so much; but given any ore and given any oil, the evidence shows that *if you add another pound of oil* your metal particles commence to stick together and commence to fall down in granules, and you get into the Cattermole sinking sphere, whereas, on the other hand, if you *diminish* it, you cease to have that selective action which is essential; you do not get any float in particular and you have gangue in it; so that it is *critical* for a given oil and a given ore, but it has variations."

Plaintiffs' counsel, in their reply brief in the Supreme Court, stated:

"It is the astonishing fact that, so far as the record here shows, with every ore the world over to which the process has been applied and with all the varying conditions of use, the *largest quantity ever used has been 4 pounds to the long ton (i. e., less than $\frac{2}{100}$ ths of one per cent)*, and that the smallest quantity has been *$\frac{1}{10}$ ths of a pound per long ton of ore (i. e., less than $\frac{1}{2}$ of $\frac{1}{10}$ th of 1 per cent)*."

We see, therefore, that not only did the witnesses in the Hyde case, whose testimony is referred to by the Supreme Court in defining the critical proportions to which the patent must be limited, confine those proportions to less than one-half of 1% on the ore, but that plaintiffs' counsel emphasized this limitation in their arguments and briefs before the Supreme Court.

We, therefore, confidently submit that in limiting the invention to the "critical" proportions "often described in the testimony," the Supreme Court limited it to that fraction of 1% which is *less than one-half of 1%*, although the claims in terms are broad enough to cover any fraction of 1% (for example, 0.999%), and that *defendant has not infringed when it has used more than one-half of 1% of oil*.

El Boleo

A handsomely illustrated article on the mining property of the Compañía del Boleo, in Lower California, is included in the Boletín Minero, Vol. IV, No. 5. No statement of the metallurgical methods is presented, these being closely guarded by the company. The plant treats 1000 metric tons daily, the ores averaging from 4 to 5% copper. There are seven blast-furnaces in operation, with a capacity of 200 tons each per 24 hours. The ores are mainly oxidized and contain a large amount of moisture as delivered to the smelter. The products shipped are black copper assaying 93% in that metal, and matte containing 63% copper. The mines lie in three different arroyos at a distance of about 19 miles from the plant, the latter being at the port of Santa Rosalia, where a harbor has been enclosed by breakwaters built of poured slag. The ores are in the form of 'mantos' or bedded deposits, slightly inclined, resting on an extensive stratum of conglomerate. The predominant minerals are the oxides and silicates of copper, with many rare species, some containing antimony. The deposits dip at angles between 10° and 15° toward the sea, that is, to the east. Water is found at a shallow depth, which is raised by large centrifugal pumps. The roof is soft and subject to eaving, which renders the problem of timbering the stopes somewhat difficult and costly. A force of 3500 workmen is employed, and a population of 11,000 persons depends upon the operation of the property. The region is a desert, nearly destitute of vegetation, and ineapable of cultivation.

Regulating Explosives in California

In order to carry out the provisions of the Federal statute that provides for the licensing of all concerned in the sale and use of explosives, a California State Advisory Committee has been formed, consisting of John M. Griffin, U. S. explosives inspector for California, chairman; John A. O'Connell, of the State Council of Defense, vice-chairman; and Will J. French, of the National Safety Council, secretary. Other members of the committee are: Jay W. Stevens, H. M. Wolfkin, chief mine inspector of California, Robert I. Kerr, H. D. Gaskill, Wm. J. Gardner, Edwin Higgins, and Chief of Police D. A. White of San Francisco. The executive committee comprises Messrs. Griffin, Wolfkin, Gaskill, Gardner, and Stevens. The address of the secretary of the committee is at the Underwood Building, 525 Market street, San Francisco.

REVIEW OF MINING

NEW YORK

COAL MOVEMENTS AND FREIGHTING.—COST OF LIVING.

Coal movements on the railroads during the past year have been estimated at 60 to 160 billion ton-miles. Even the smaller estimate is gigantic, and suggests consideration of the question of unnecessary coal transport. The adoption of the zone system of coal distribution, as practised in Great Britain, might well result in haulage economies. Storage of coal on Manhattan Island (New York) is imperative if delays and heatless Mondays are to be avoided in the future; and the Fuel Administration now suggests that provision should be made by private consumers for winter needs during the spring and summer. Unfortunately facilities are generally lacking. The mild weather of late has materially helped the freighting situation, and larger supplies of coal are being received.

That the recent chaos in transportation was in part due to faulty equipment and lack of cars has been demonstrated by late statistics. At one time no less than 57 miles of track between New York and Chicago was appropriated for stalled cars needing repair. There are approximately 2½ million freight-cars in transit, and up-keep costs are naturally considerable and skilled labor scarce. The freight congestion problem has been alleviated by a new system recently inaugurated on the Pennsylvania Railroad for the handling of 'less-than-carload' lots, which has proved highly successful. Full carloads are now only carried, and 654 cars are saved daily from unnecessary service. Twenty-five local freight-trains have been discontinued, their places taken by a considerably reduced number of bi-weekly or tri-weekly 'pick-up' trains.

The Food Administration is rapidly gaining the confidence of the majority. Profiteering is still rampant in foodstuffs, but drastic action has sounded a warning note and it is generally realized that things might be much worse. One egg-juggling business was recently put out of action by the authorities and others will doubtless take note. In the case in point it was disclosed that two persons formed four companies to operate in New York to boost the prices of eggs by the simple expedient of passing the goods through the books of each company, with added increments of profit, until they finally emerged with a 'face' value some 14c. per dozen higher than the price originally paid. This case will serve as an explanation of the ability of these gentry to bluff the public with oft-repeated statements as to the insignificance of the profits made by individual concerns. The Federal Milk Commission has permitted the present high price of milk to remain in force for the present, and it is to be regretted that it were apparently unable to force a reduction. In other countries milk is milk, and guaranteed as such by the proper authorities. Here it seems to be a case of "where nature ends and art steps in," and the people have to pay for a competitive advertising war between the various controlling interests. The need for an additional 50,000 beds for tubercular patients in this country, to control the disease and prevent its spread, is a side issue; but at the present price of milk the invalid poor must content themselves with the sight of a bottle of milk pictured in an expensive advertisement. Sugar has afforded a means for profiteering by wholesalers, and in one case a refund was

ordered by the Federal Food Board. This case showed that the retailer was forced to buy sugar at a price well above the highest he could possibly charge his customers. In another case a firm of New York wholesalers have had their license annulled for the duration of the War for profiteering in this article. These prosecutions show that the authorities are alive to the situation. The poor who were obliged to buy their coal from peddlers during the recent cold spells were shamefully victimized, and were forced to pay from 80 cents to \$1.25 per 100 lb. Mayor Hylan intends to take steps to insure better facilities for the delivery of coal to small consumers, and a reasonable price will probably be fixed for next winter. If this proves impracticable the City will probably take over control of the matter. The increased cost of the Victory Loan, due to the higher price of wheat substitutes, has been estimated at one-tenth of one cent. Bakers gave out that a one-cent increase would be charged and gleefully anticipated the excellent increase in profits. Mr. Hoover objects to the increase as unjustified, and the bakers' attitude naturally elicits little sympathy. The price of wheat has been virtually fixed at \$2.20 since last summer, and a bill was recently proposed to raise this to \$2.50 or even \$3. This has now been negatived by President Wilson who has, however, promised that the farmers shall have every facility. It was generally realized that there was no justification for the proposed raise, but farmers maintained that they are entitled to rates comparable to the present price of cotton. With wheat at \$2.20 they argued that an equivalent price for cotton would be 20 cents and not 32 cents as it is quoted at present. A further cause for the abnormal increases in certain expenses is the lack of recognition of a smaller coin than the nickel by certain concerns. An example of this is seen in the recently published report of a local restaurant company that caters to an immense number of the workers in offices and factories in this city. Profits show a rise of nearly 200% and this may be largely attributed to the fact that, when the increase in the price of an item on the menu is considered, at least a five-cent addition is made. Thus a large proportion of the items are increased 100% to the customer, whereas the additional cost to the restaurant is probably nearer 10%. The situation between landlords and tenants of apartments is becoming strained and remedial measures are demanded. The shortage of coal gave landlords an opportunity to repudiate their obligations, and the excuse was extended long after the coal was available to explain the absence of heat and hot water at any time the landlord wished. Tenants have practically no redress. About 80% of the population of New York City live in apartments, the majority being on a monthly tenure. The law states that a landlord may compel a tenant to vacate after a few days notice, and if the tenant objects to higher rent, entire absence of heat in a so-called steam-heated apartment, and other discomforts, he can leave, to probably meet similar treatment elsewhere. There have been no less than 32,000 dispossession or ejection proceedings commenced by landlords in this city during the winter. These cases have been the result of an attempt on the part of tenants to get common justice by withholding rent when the landlord failed to provide heat or refused to make any deduction when heat was withheld. Verdicts are invariably in favor of the tenant, and a deduction of from 10 to 20% of the rent due is

ordered by the judge. It is satisfactory that temporary redress can be obtained in this manner but the fact remains that the law is antiquated and altogether favors the landlord, leaving ample loopholes for the latter to victimize his tenants systematically. The situation is largely the result of a traffic in apartment-house leases whereby each new lessee—and he may only hold the property a few months—endeavors to make a larger profit out of the bulk payment made to the landlord than did his predecessor. If the tenant cares to take the matter of the failure to supply heat to the courts he can only claim the exact sum expended on extra gas used to warm the only room in the apartment that can be warmed—the kitchen—where he must perforce spend his time in a fume-laden atmosphere. The lessee will then probably exercise his legal right to evict him after five days notice, and numerous cases of this kind have occurred during the recent below-zero weather. Further, lessees have organized and not only are they offering effective opposition to the tenants' demands for simple justice but should a tenant object, obtain a verdict for a rebate from his rent and be immediately ejected from his apartment, his troubles do not end there. Tenants who refuse to take whatever treatment is meted out to them 'lying down' are placed on a 'black-list', and are promptly refused admittance to other houses. Legislation is being considered to remedy this pitiable state of affairs, but tenants have practically no organization, they are seldom even acquainted with their neighbors in the same house, and there are no corporate funds. It is proposed to make a landlord or lessee liable to maintain a living temperature in a steam-heated apartment or agree to a reduction in rent due. It is also suggested that landlords should be forbidden the right of ejection of tenants as long as the latter pay their rent and as long as the landlord has no just cause for complaint. One champion of tenants' rights suggests that the city should make a survey of the coal in apartment-houses, to see that landlords and lessees have purchased sufficient for the winter. In default of this the city should make the necessary supply and recoup the expense involved by a lien on the rents. The lessee evil should be abolished and landlords should be made to understand that their property holdings involve certain moral obligations; and that subletting the apartment house to an unscrupulous lessee, who may have no credit to buy sufficient coal, does not absolve them from blame. The probable spread of disease by conditions involving lack of proper ventilation and existence in a fume-laden atmosphere was anticipated in a previous letter. This forecast was justified and it is now reported that unhygienic conditions are responsible for an enormous increase, estimated at 100%, in cases of diphtheria, scarlet fever, measles, and similar complaints. The spreading of these diseases is facilitated by the congestion at normal times but quickly aggravated by the unhealthy conditions caused by the rank profiteering of many lessees and landlords. Preventable waste at such times as this is a tragedy and it is unfortunate that a section of the community regards the question from one standpoint only, that of material and personal loss. Wastage of labor caused by the unthinking few and paid for by all is a serious factor in the present cost of living. Shoppers may be divided into two classes, namely, those that have an intelligent conception of what they want to buy, and those that systematically purchase almost anything they see, knowing full well that they will avail themselves of the return privilege. A reliable authority has stated that 25% of the goods bought in retail stores are returned. The great bulk of the shopping public seldom or never takes advantage of this facility, but this section has to pay for the indecision of those individuals who help to materially raise the ultimate cost of retail goods by doubling or trebling the labor involved for each transaction, and by depreciating the value of the goods they handle 'on approval'. This evil is particularly noticeable in New York where wastage of this kind is rampant.

CRIPPLE CREEK, COLORADO

LEASING AND DUMP TREATMENT.

Victory Gold Mining Co. has purchased the Elmer Smith lease on the Howard shaft and 5 leased blocks of the Mary McKinney Mining Co.'s estate on Gold hill. Consideration is reported to have been \$10,000. The Howard flats have produced approximately \$2000 gross, and the property, with large area undeveloped, is still producing heavily.

Wild Horse shaft, at east end of Wild Horse mine on Bull hill, has been leased to Crook and Pratt, who will mine ore from a dike extending south of a line between the Wild Horse and Gleason shafts. This dike measures from 75 to 100 ft. in width, and carries gold-bearing clay. Ore can be mined profitably, with low treatment charges prevailing. Property is owned by the United Gold Mines Company.

Dumps on El Paso Consolidated property on Beacon hill are to be shipped to Golden Cycle mill at Colorado Springs, at the rate of a carload daily. Careful samples have shown an average of \$3.10 per ton. This can be treated profitably.

Large quantity of dump ore continues to move from the Stratton estate to the Golden Cycle mill at Colorado Springs, also Portland and Independence mills at Cripple Creek.

LEADVILLE, COLORADO

DRESSING MANGANESE ORE.—IRON-SILVER ORE DEVELOPED.—GOLD IN THE IBEX.

The first 100-ton unit of the Star Consolidated Mining Co.'s 300-ton mill has been completed by G. E. Cramer. A trial was made last week, and after necessary adjustments will be ready for regular operation. Capacity is expected by the end of March. This plant will dress ore from large bodies of low-grade iron-manganese deposits. Manganese content of crude ore ranges from 15 to 20%, and concentrate is expected to contain 30% and low in silica, a marketable product. Treatment is as follows: Ore is hoisted through No. 5 Star and Ladder shafts, 200 ft. on either side of the mill, and trammed over trestles to receiving-bins. These feed a revolving-screen with 1-in. holes. Coarse ore from screen is shoveled into a crusher. Fine ore from screen and crushed ore drop into another chute feeding a belt-conveyor. This carries ore to the top floor of the mill, where it goes through another screen with ½-in. holes. The oversize is fed direct to a Chalmers & Williams disc-crusher. After passing through screen and crusher, all ore is ½ inch or under, and drops into a bin on the lower floor. From this it is elevated by two belt-conveyors to feed-tanks on second floor. From tanks the ore and water flow to jigs that separate the silica from the iron and manganese. Coarse concentrate is caught on the upper jigs and fine material on a lower set. The silica is washed off into a settling-tank, from where it is trammed to dump. Concentrate is put in bins on bottom floor, trammed to an elevator near railroad, and dumped directly into cars. The plant is heated by exhaust from the large steam hoists at the shafts. Construction will be started on No. 2 and 3 units when No. 1 is in complete order. Cost of mill when complete is estimated at \$50,000. Mr. Cramer is producing 200 tons of manganese daily, marketable without concentration. Some lead ore is also being shipped.

Manganese ore in considerable quantities was opened in the Jason mine in Poverty Flat district, and Mrs. F. M. Doty of Denver, who recently sold her lease on the property for \$10,000, has acquired a lease on the S. Small ground adjoining. She believes that the Jason deposit extends into these claims. The Seeley shaft is to be equipped with hoist, etc., re-timbered to 300 ft., and exploration started.

Development at the new Dunkin shaft on Fryer hill is proving that property to contain the largest and highest grade iron-silver deposit in the district. Ore was first found at a depth of 80 ft., underlying a stratum of flint. Shaft is now

over 100 ft. deep, the bottom in ore. Driving into the deposit in two directions shows the shoot to be continuous so far. Shipments were started last month, but shortage of cars has prevented operations at capacity. It is estimated that 5000 tons of ore is blocked out, and production will be from 50 to 100 tons daily after April 1.

High-grade gold ore has again been discovered in the Ilex mine on Breece hill, the first time in many months. Recent discoveries were made in widely-separated parts of the property. Snowstorms have hampered work at this interesting mine.

Lessees at the Nisi Prius mine in Iowa gulch, where a large body of manganese was discovered last year, are to sink their shaft another 50 ft. in the spring. Shipments are now 50 tons of manganese daily. The deposit is persistent below the present workings, and deeper workings are expected to find better ore.

HANOVER, NEW MEXICO

IRON, ZINC, AND SILVER PROPERTIES OF FIERRO, HANOVER, AND KINGSTON

KINGSTON.—Empire Zinc Co.'s work in this field and the rise in silver has resulted in more work being done here during the past year than in the preceding decade. The Empire company

quantity for 10 years. This company is also shipping ore to the Copper Queen smelter at the rate of 900 tons per month. It averages nearly 5% copper and 50% iron.

SUTTER CREEK, CALIFORNIA

ARGONAUT AND CENTRAL EUREKA SINKING SHAFTS.

JACKSON.—Argonaut company is again preparing to deepen its shaft 150 ft. It is 4785 ft. deep on an incline of about 60°, equivalent to a vertical depth of 4145 ft. To facilitate hauling ore, a large hoist was installed at the 3900-ft. station a few years ago. This machine is practically a duplicate of that on the surface, and is the largest underground hoist on the Mother Lode. Ore is being hoisted from the lowest levels of the mine. Orebodies at 4500 ft. are yielding good ore, so are the 3600, 3750, 3900, and 4050-ft. levels. The vein is regular, averaging from 8 to 12 ft. in width, being of fine value throughout. The 500-hp. double-drum electric hoist on surface brings the ore from 3900 ft. to surface in 4-ton skips. It is there automatically dumped into storage-bins in the head-frame, and from there conveyed to the new 60-stamp mill just west of the shaft. N. S. Kelsey is manager of this dividend-payer.

SUTTER CREEK.—At Central Eureka mine the shaft has been sunk 30 ft. below the 3425-ft. level, two shifts engaged. Specimen ore has been found several times recently at 3350 ft.,

NORTH CAMP, KELLY, NEW MEXICO

has started development on the Grey Eagle group. Its total holdings approximate 50 claims.

Franklin company, on Eullion hill, has resumed work. Both shipping and milling ore is being developed, and future prospects are good.

This district was formerly a large silver producer, and present prices make prospecting worth while. The real future of Kingston depends on the successful exploitation of its zinc deposits. The fact that so conservative a corporation as the Empire Zinc Co. has taken large holdings here, remote from railroad transportation, augurs well for future possibilities.

HANOVER.—Republic M. & M. Co., driving east on an orebody on the 150-ft. level, has opened ore assaying as broken over 40% zinc. On the 200-ft. level a fine body of 20% milling ore is being developed. This mine, a prospect a year ago, has approximately 100,000 tons of minable ore averaging 15% zinc.

United States Copper Co. is making good progress in sinking its No. 2 shaft. Station at 400 ft. will be cut this week. It is reported that ore has been found between the 300 and 400-ft. levels.

FIERRO.—Hanover Bessemer Iron & Copper Co. is shipping 20,000 tons of iron ore per month to the Pueblo plant of the Colorado Fuel & Iron Co. The present contract calls for this

where stoping is in progress, and the average of ore being extracted from this level is increasing mill-ore encouragingly. While indications are good for pay-ore near present bottom of mine, no permanent station was cut below 2350 ft. when sinking was discontinued early last year, it being deemed best to increase the depth before attempting extensive lateral development.

TINTIC, UTAH

ACTIVITIES IN EAST AND WEST TINTIC, EUREKA, MAMMOTH, AND SILVER CITY.

EAST TINTIC.—Considerable new work is to be done in this district during the coming season, both by companies already operating, and by others preparing to enter the field. In the North Tintic area there will also be extensive exploration.

EUREKA.—Lehi-Tintic has opened rich copper-silver ore at a point 2000 ft. in its adit and depth of 600 ft. At bottom of 50-ft. winze is 3 ft. of ore. A new air-hoist is being installed to sink deeper on this shoot. As soon as roads are dry shipments are to be commenced.

Tintic Standard company is to sink three shafts. One, in central part of property, is down 175 ft. below the adit-level.

Another is to be started early in the summer, and the third will be sunk near the Zuma property. The Standard ground is so extensive that three shafts are necessary for quick development.

Eagle & Blue Bell shipped 80 cars of ore during February. This is the maximum allowed by the smelter. Station is being cut on 2000-ft. level, after which a drift will be driven to cut the vein, probably 300 ft. from shaft.

North Beck Mining Co.'s shaft is down 700 ft., on its way to 1000-ft. depth.

At depth of over 500 ft. in Copper Leaf shaft, gas was encountered, necessitating installation of a blower. Work is suspended until this is done.

MAIMOTH.—Grand Central shipped 100 tons of ore daily in February. Much of this is coming from an apparently new orebody, being developed by three raises above 2000-ft. level.

SILVER CITY.—Tintic Milling Co.'s plant is working well, according to the manager, G. H. Dern, treating ore from the Dragon, Iron Blossom, and other mines. February output was worth about \$70,000.

WEST TINTIC.—Operators in this and the Erickson district are highly satisfied on account of the railway to be constructed into the region.

COLEMAN, TEXAS

OIL DEVELOPMENTS IN COLEMAN, PALO PINTO, AND STEPHENS COUNTIES

All of that region in which the Pennsylvanian rocks outcrop, and a large part of that covered by Permian rocks, from Wichita Falls to Brady, north and south, and Parker county to Scurry county east and west, is being covered by lessees for oil and gas.

There are several good wells in Stephens county yielding over 100 bbl. per day. The McClusky well at Ranger, Eastland county, is the only real well in this part of Texas. It is about four months old, and still flowing over 1000 bbl. This well is 3440 ft. deep, and oil comes from the Bend series.

The Lee well at Caddo, Stephens county, is 3181 ft. deep. Its production is from the Bend also, and is good for 200 barrels.

The Morris well, 9½ miles north-east of Coleman, Coleman county, owned by the Magnolia Elizabeth company, is 3450 ft. deep. Oil comes from the Bend series. This well is good for 35 bbl. per day.

At Brownwood, 400 wells have been drilled. These are from 200 to 600 ft. deep. Companies drill four to eight wells on a town lot. Average well at Brownwood is good for about two barrels per day.

Engineers would be interested in the equipment at these wells. Anything that will punch a hole is used, and the casing in many cases is galvanized sheet-iron drain-pipe. Leases at Brownwood have sold 'very high,' in some instances they are asking as much as \$400 per acre bonus and ¼ royalty for town lots, 1¼-acre plots. Lease men are paying 50c. to \$10 per acre. Average bonus is about \$1. A lease carries ¼ royalty and \$1 per acre rental per year.

A 'spring drive' on the 'general public' is under way. Some \$20,000,000 oil companies will soon be selling stock, and the unsuspecting public will be easy 'meat.' At present there is nothing here to justify the boom. However, there are several areas in this region well worth prospecting, and from which oil in commercial quantities will be produced; but something should be done at once to protect the people from stock-selling 'sharks.'

The Texas & Pacific Coal Co. has the largest production at present in this region. It owns the Ranger well, mentioned above; and owned so many leases that it was lease poor, and had it not been for the Prairie Oil & Gas Co. coming to the rescue recently it would have lost its leases or gone bankrupt paying rentals. There are lots of 'lease hogs' in this region.

The Prairie company has acquired a half working-interest in a large part of the T. & P. Coal Co.'s holdings. It secured all of the producing area except the old Strawn field. The Prairie will most likely construct a pipe-line to the field, and from reports will drill 20 wells for the T. & P. company. For this it gets a half interest in the property. T. & P. shares are selling around 318. Stock of this company has just been increased from \$4,000,000 to \$5,000,000, evidence of the 'trend of the times.'

TORONTO, ONTARIO

LABOR SITUATION IN ONTARIO.—PORCUPINE, KIRKLAND LAKE, AND FORT MATACHEWAN.

Labor conditions in mining regions of northern Ontario are gradually improving. At Cobalt, Kirkland Lake, and outlying districts, mine managers state that they have no difficulty in securing all the men they need. Conditions at Porcupine are rather less satisfactory, as owing to the policy of the Hollinger and McIntyre in paying much higher wages than the general rate, there is dissatisfaction and restlessness among those employed elsewhere, and men are disposed to leave and look for work in preference to accepting a moderate wage.

PORCUPINE.—McIntyre is steadily improving its position. Gross profits are 25% of issued capital. Three shafts are down 1000 ft., and main workings are being sunk to the 1325-ft. level. Width and value of the orebodies is found to increase with depth, and ore-reserves are worth approximately \$6,000,000. Average gold content is \$10 per ton.

Dome Mines Co. is working on a comparatively small scale, practically confined to sinking the main shaft from 800 to 1000-ft. level. This may be continued to 1500 ft. Work is being done directly by the company and not under contract, as was originally proposed.

Dome Lake has cut a high-grade orebody for 110 ft. An extension of No. 3 vein has been cut on 400-ft. level, 750 ft. from main shaft. It is heavily mineralized, and shows free gold.

Davidson mine was inspected on February 18 by a large party of Toronto, Buffalo, and Detroit business-men. Ore blocked out down to 200-ft. level is estimated at 100,000 tons, averaging \$10 per ton. Large bodies of low-grade ore are considered to exist below 200-ft. level.

KIRKLAND LAKE.—Development of this goldfield is handicapped by high cost of mining and milling, about \$10 per ton. In addition to the increased cost of labor and supplies, disadvantages are hard rock, lack of persistence in ore-shoots, and undesirable minerals rendering treatment difficult. Graphite is one of these interferences. Richness of much of the ore is expected to overcome this drawback, and opening of new mines, increased milling facilities, and reduction in present high costs may enable \$8 and \$10 ore to be profitably mined.

Teck-Hughes in January treated 2177 tons of \$8.62 ore, a considerable increase over any previous month.

Elliott-Kirkland cross-cut on 400-ft. level has passed through 28 ft. of vein formation, part of which is said to be high grade.

Canadian-Kirkland shaft on No. 2 vein is down 75 ft., at which point ore assays from \$3 to \$12 per ton. Ore from No. 1 vein, at a depth of 35 ft., is richer.

FORT MATACHEWAN.—Increasing interest is being taken in this gold district, which is about 38 miles up the Montreal river from Elk Lake, and includes the townships of Powell, Cairo, Alma, and Yarrow. Recent sale of the Otisse property for a large sum brought the field prominently into notice, and a good deal of capital is seeking investment here. The first claims were staked in the district previous to the discovery of silver at Cobalt. There was a rush of prospectors in 1911, and another last year, when 1000 claims were located. Value of the field has yet to be determined, and it is expected to be the scene of much activity as soon as spring sets in.

THE MINING SUMMARY

ALASKA

JUNEAU.—Estimates for February operations at Alaska Juneau are as follows:

Ore milled, tons	97,155
Assay of mill-feed, cents per ton.....	60
Assay of tailing, cents per ton.....	15
Gold recovered, cents per ton.....	45 or \$41,000
Cost of milling, cents per ton.....	46
Cost of mining and tramming, cents per ton...	20
General charges, cents per ton.....	4
Total operating expenditure	70 or 69,000
Operating loss	\$25,000
Expenditure on capital account.....	21,000
San Francisco charges	5,580
Total estimated expenditure	\$95,580

F. W. Bradley states that the low value of the mill-feed is due to excessive mixture of waste with the ore, caused by what has turned out to be an erroneous lay-out of the pre-mining work. To overcome this, the new, or 410 stope, is now being opened with a cut-out area on February 10 of 18,434 sq. ft., assaying, up to that date, \$1.49 per ton. Maximum crushing capacity of the whole mill for February was only 3470 tons per day. Mill is not only a disappointment in its small capacity, but also in its high costs. These defects can be somewhat overcome by rejecting coarse waste before any fine grinding. Pending completion of an installation for this purpose, the plant will hereafter be operated but one 8-hour shift per 24 hours.

ARIZONA

ALBU.—Powder in drill-hole in steam-shovel pit of New Cornelia became ignited on February 27, resulting in explosion that killed two men. This is company's first fatality.

GLOBE.—Adjoining the New Dominion and Big Johnny properties the Moline-Arizona Copper Co. is to develop the old Mineral Farm mine. B. F. Baker is in charge at Globe.

JEROME.—United Verde Copper Co. has stopped night shift, and will operate the mine with two 8-hour shifts with more men.

Court has ousted A. B. Frame from the Jerome-Portland, and directed that the stock held for him in escrow be placed in treasury of company.

Considerable trouble is being experienced with water at the Gadsden mine. Additional pumps are required.

Jerome Grande company, which has taken over the Verde Grande, is to unwater shaft and start development.

A 70-hp. boiler and 4-drill compressor have been purchased for the Annie Gold mine for sinking shaft to 500-ft. level from present 160-ft. level. About 3000 ft. of work has been done.

Jerome Daisy has been forced to close down for lack of funds. Shaft has reached a depth of 250 feet.

General Development Co. (Lewisohns) is reported to have paid \$50,000 toward further control of Jerome Copper Mining Company.

Adams and Townsend are shipping tungsten concentrates from their property in the Aquarius mountains. Concentration is done by hand-jigs, owing to shortage of water.

KINGMAN.—Much of the active and profitable operations of the mining industry of north-western Arizona can be credited to the service of the Desert Power & Water Co. of Kingman, a concern that now has an investment of \$750,000, with lines extending to Oatman, Chloride, and other producing districts. Improvements made during the past year cost \$200,000, including a 3000-hp. Atlas-Clahmers turbo-generator, with corresponding boiler additions. At an expense of \$90,000 a line is to be constructed to Hackberry, and another will extend to Cyclopic camp, 30 miles north of Chloride. A new customer is the Gold Road, lately revived; while the Schuykill company at Chloride will take the place of the Tennessee, lately taken over by the Schuykill.

KOFA.—King of Arizona gold mine in Yuma county is reported sold for \$50,000 to J. W. Johnson, representing Eastern people.

METCALF.—Mines of the Clifton-Morenci-Metcalf district are gradually increasing their forces, having about two-thirds normal number at work. In accordance with ruling of Federal Board, only married men who worked immediately before the strike are being employed. This ruling does not apply to skilled men.

Arizona Copper Co.'s concentrator at Clifton is in operation, ore coming from the Metcalf mines. This company is preparing to churn-drill in the Metcalf district. Two 1500-ft. Armstrong drills of latest type are to be in operation shortly. They are equipped with 25-hp. motors. Sites for 16 holes have been located and a road to them is completed. Depth of first holes will be 1000 to 1500 ft. The area to be drilled has never been prospected, but the surface indications are good, and it is expected that valuable orebodies will be discovered.

MIAMI.—Inspiration Consolidated is operating at 80% capacity.

OATMAN.—Two Calyx drills have arrived here; one is to be installed at the Telluride and the other at the Amalgamated. Engine used for operating hoist at Ivanhoe shaft will supply power for drills. These are capable of cutting a 6-in. core.

TUCSON.—Projects to erect reduction works near here are as follows:

Pima Smelter & Refining Co. has been incorporated by Alford Roos, G. P. Myers, and J. W. Bogan, capital \$1,000,000, to move a smelter from Socorro, New Mexico, to Tucson. Another scheme was to raise \$750,000 at Tucson and \$2,500,000 elsewhere, and erect a large plant within two years. Third idea was to build a large concentrator to treat tungsten, molybdenite, and other rare ores.

A. Roos states that the smelter project at Tucson is practically financed, and the plant will be shipped from Socorro in 10 days.

CALIFORNIA

Report of Industrial Accident Commission for year ended June 30, 1917, has just been published. It covers 158 pages, and is replete with charts, tables, and interesting data dealing with accidents, compensation, insurance, and safety.

Platinum resources of this State and Oregon have been investigated by U. S. Geological Survey and State Mining Bureau, who summarize as follows:

Possibility of increasing production of platinum metals depends on improvements in recovery methods now used, on ex-

tension of these methods to areas that are known to contain these metals but that have not yet been mined, and on discovery of new productive ground in north-western California and south-western Oregon, where prospects seem good. Streams that carry insufficient gold and platinum to pay for mining at former prices might now yield a profit. Streams that drain areas of serpentine would seem to be particularly favorable for prospecting. At no place are the platinum metals concentrated in large quantities. Being rarer than gold, they are harder to find than the yellow metal. Iridium is in great demand, and the fact that it forms 10 to 40% of platinum metals in nearly all the placer deposits in United States is a special incentive to search for more of them. Risk that must be taken to find and develop new sources of supply is great, but the pressing need would seem to justify it. Elimination of litigation and equitable settlement of questions regarding surface rights and underground rights in drift mining, and regarding the distribution of water for irrigation, power-plants, and mining might also increase the output. Present price of platinum metals, which is much higher than that of gold, does its share in encouraging production.

ALLEGHANY.—In suit of Sixteen-to-One Mining Co. v. Twenty-One Mining Co., dispute over certain mineral land, District Court at San Francisco gave title to plaintiff; and in suit between same parties for \$100,000 damage for ore extracted during alleged trespass, plaintiff also won, but as there was no wilful trespass, cost of mining was to be deducted from the \$100,000. As this cost was not fixed by the jury, the verdict was faulty, and no judgment was entered. A re-trial will fix the cost.

ALMADEN.—New Almaden company is demolishing old distillation furnaces, foundations, and flues; washing the loose material, and has one furnace treating brick saturated with quicksilver. A fair quantity of mercury is being recovered. Save for lessees the old mine is idle. At the company's Sengtor mine, 7 miles distant, two furnaces are distilling metal from cinnabar.

ATOLIA.—Atolia Mining Co. held its annual meeting at San Francisco on February 21, and the following board of directors was elected: E. C. Voorheis, president; F. W. Bradley, vice-president; E. A. Stent, secretary; with C. H. Kroll and David Atkins.

CORAM.—First National Copper Co., operating the Balaklala mine, declared dividend of 15c. February 25. Three hundred tons of ore is shipped daily to Kennett smelter under contract in force for next seven years. Recent work in new ground is reported to have opened good ore.

Shasta King, the principal mine of the Trinity Copper group, is being worked by the United States Smelting company under bond and option. More men have been engaged preliminary to a larger output.

CRUCEBO.—Tecopa Mines Co. may erect a smelter either at this place or at Tecopa. L. D. Godshall of Los Angeles is in control.

OROVILLE.—At an elevation of 1150 ft. above sea-level and 750 ft. above the Feather river in Butte county, and 14 miles from Oroville on the Western Pacific, are the California National Gold Mining Co.'s claims. Property was examined in 1917 by Chester F. Lee, and Morton Webber. It is now under development, and is expected by management (C. H. Waters in charge) that it may prove to be one of the largest low-grade properties in this State. Various assays indicate an average of \$2.50 gold per ton, although one gave \$1.90. This is the feature of this mine: a large deposit of soft low-grade ore, well situated for mining by adits, and simple treatment. If \$2 per ton is extracted, total costs are not expected to be over \$1 per ton. The deposit seems to be a replacement of amphibolite country-rock by silicious and ferruginous matter. Observed minerals are quartz, decomposed feldspathic matter, and finely-disseminated iron pyrite. The body is stated to be

480 ft. wide at right angles to the dip. No work has been done to determine its length. Company has an 11-mile ditch and flume, and plenty of water.

PLACERVILLE.—Pacific Gold Mining Co., operating Martinez mine, has driven a 1000-ft. adit, opening mine to depth of 520 ft. Low-grade ore was opened several months ago.

In Red Wing mine, near the Martinez, 200-ft. level cross-cut

CALIFORNIA NATIONAL PROPERTY IN FEATHER RIVER CANYON.
NEAR OROVILLE, CALIFORNIA

is in 330 ft., cutting veins from 3 to 14 in. wide, assaying \$15 per ton.

Cincinnati mill is crushing \$3 to \$4 ore, said to be mined and treated at cost of \$1 per ton.

WINTHROP.—Bully Hill mine is producing 100 tons daily, shipping to Kennett smelter. Good ore has been opened on 900-ft. level and drilling is to prospect at depth of 1100 ft. Bully Hill is being developed by the Arnstein company, under a bond and option, and it is reported that a flotation plant may be installed soon.

COLORADO

CARIBOU.—Despite winter weather several properties are shipping ore.

Caribou company has erected a compressor and re-timbered its shaft. No. 10 level is to be driven in new ground. Part of old ground is to be leased. Company has acquired Grand County claims adjacent.

LEADVILLE.—Chimax Molybdenum Co.'s new mill is working well, producing high-grade concentrate. H. L. Brown is in charge.

Molybdenum Products Co. is building a mill at Burfehr's spur. A. B. Scott is manager.

Wilson mill at Frawley, formerly Robinson, has been overhauled to treat lead-zinc ore.

NEDERLAND.—Malmö Mining & Milling Co. has been organized by C. E. Bradenburg and Eastern people. Machinery is to be ordered. Property is considered to have good possibilities.

I. N. Bair and others have secured the Catastrophe tungsten mine in Boulder canyon. Ore is rich in ferberite.

Rare Metals Co.'s mill at Rollinsville, 4 miles from Nederland, is to resume ore-dressing, in charge of Nelson Franklin.

Cross tungsten mine at Cold Springs is showing one of the best deposits in the county. Wolfe Tongue company is owner.

Potosi mine at Caribou is developing rich silver ore. Shipments are to be made regularly.

Country between Cardinal station and Caribou will be extensively explored this year.

IDAHO

LEADORE.—Sunset mine near this place requires a mill for profitable operation. A carload of silver-lead ore daily was sent to Utah during last summer, but this only paid expenses. Reserves are estimated at 400,000 tons. C. O. McFall is largely interested in this, the Greenback, and Salmon River mines nearby.

MULLAN.—Federal M. & S. Co. pays 1½% dividend on March 15, equal to \$209,757. This is on preferred shares. The Morning mill is again treating ore.

Development in Copper King Mining & Smelting Co.'s ground has been changed to driving east on high-grade milling ore, and west on 6 ft. of rich copper ore. Samuel Edelstein is president.

National Copper Mining Co.'s 500-ton mill is working at part capacity, producing over 300 tons of concentrate per month. No. 12, 14, and 15 levels supply the ore. No. 15 is 2200 ft. from the surface. A little profit is being made. Charles McKinnis is manager.

Donald F. Fitzgerald, promoter of Mineral Farm Mining Co., and former president of a brokerage concern with offices in St. Louis, Detroit, and Chicago, pleaded guilty in Federal Court at St. Louis on March 4 to a charge of using the mails to defraud. He was sentenced to two years in the Leavenworth Federal prison. Information gathered by Federal authorities indicated that 200,000 shares in Mineral Farm company had been sold at the St. Louis brokerage office since 1916, and that no dividends had been paid.

MICHIGAN

HOGCHITOX.—Wolverine company is trying mules for underground tramming, also a compressed-air shovel to load cars. This shovel fills a car in 2½ minutes, against 10 minutes by 3 men. Trammers are short, and mechanical systems will help this deficiency.

Mayflower-Old Colony shaft is down 240 ft. Modern surface plant is complete. Shaft must be sunk to 2100 ft. before lode is cut.

Franklin No. 2 shaft is down to No. 18 level, where station is being cut. Daily shipments are 1200 tons.

Ahmeek is shipping 4300 tons per day.

Mass Consolidated production in 1917 consisted of 30% mass and 'barrel' copper. Total output was 4,000,000 lb. Costs were 19c. per lb. Over \$80,000 was spent in construction, mostly employees' homes.

MONTANA

BUTTE.—Alice zinc mine of Anaconda group resumed operations last week, after 9 months shut-down. Leo McGrath will be in charge of 150 men, producing over 200 tons daily.

West side of this district is receiving additional attention. Butte & Plutus Mining Co. is latest company to start work. A two-compartment shaft is being sunk 100 ft. north of Hibernia claim of Davis-Daly, and 300 ft. from Nettie claim

of Anaconda. Vein carries silver, also manganese. D. J. McGrath is manager.

North Butte company has purchased Monitor claim on east side for \$150,000 cash.

HELENA.—Helena mine has dispatched 47 carloads of ore to smelter, and ore-shoot, which is 200 ft. long, continues strong above 300-ft. level.

New 80-hp. boiler has been added to Looby shaft of Cruse Consolidated. Shaft is to be deepened below 150-ft. level.

A. B. Woolvin, of New York and Duluth, has secured option on the Byrnes-Coffee claims, and is expected to acquire control shortly.

Rock Rose Mining Co. is shipping a good grade of lead-silver ore to smelter.

Thomas Cruse Development Co. is making regular shipments from above 640-ft. level.

NEVADA

GOODSPRINGS.—Favorable reports have been published regarding the Red Streak Copper, Copper Chief, Copper Peak, and Oro Amigo mines; also at 900 ft. depth in the Yellow Pine.

During 1917 the Yellow Pine Mining Co. produced 20,165 tons of ore, 11,664,820 lb. of zinc, 4,984,338 lb. lead, and 125,246 oz. silver, making a profit of \$653,199. Dividends totaled \$360,000. The cash revenue is \$230,000. The important development of the year was on the 700-ft. level. A number of improvements were made to surface equipment.

JARBIDGE.—Elkoro Mines Co. has started its new 150-ton cyanide mill. Plant is operated by electricity, generated at Thousand Springs. Aerial tram carries ore from mine to mill. Development has been in progress two years, and opened plenty of ore for a long run.

KIMBERLY.—Giroux mill of Consolidated Coppermines resumed ore-dressing last week, after several weeks suspension. Mine developments are reported as encouraging.

LAS VEGAS.—Manganese Association, leasing a large manganese deposit, near here, has, it is reported, closed a contract to supply Saffern & Co. of New York with 90,000 tons. Price on cars in the East is \$42 per ton. Said to be 150,000 tons available.

LOGANDALE.—Cinnabar is reported to have been found 6 miles west of this place in Clark county. Locators were D. A. Potter, Henry Rice Jr., and others. Ore assays up to 10% mercury.

MILL CITY.—Tungsten is being mined from a new area 8 miles west of this place on the S. P. line. Lessees are busy. During February, Friedman extracted ore worth \$30,000; while Forge and Stouk took out \$20,000 in 60 days. Property of Thomas Sutton shows good ore at 100-ft. depth.

PIECHE.—Prince Consolidated in February produced 12,000 tons of ore. The mine is in good shape to continue yielding 400 tons daily. Regular dividends were paid to end of 1917, but were suspended until taxation is decided.

TONOPAH.—Production during week of March 2 was 10,581 tons valued at \$179,877; and last week 8873 tons worth \$150,841.

Tonopah Extension in January yielded 862 oz. gold, 87,321 oz. silver, and profit of \$13,459 from 8873 tons of ore.

PIONEER.—Consolidated Mayflower company has opened a good deal of high-grade ore, and is shipping some to the Mammoth smelter in California. A recent carload assayed \$22 per ton, mostly gold. Part of the mill is operating, and 15 stamps will be dropping in near future.

OKLAHOMA

COMMERCE.—Big Seven Lead & Zinc Mining Co. is constructing surface tram and tunnel to connect its mines with the mill and mines of its Queen City property, recently acquired. This will improve moving ore at less cost.

PIECHE.—Kanoak Metals Co. has two mills operating at

Picher, a third is under construction at Douthat, and a fourth is to be built near Badger. One of the Picher plants treats 450 tons of ore daily. Ore is mined at a depth of 190 ft., and averages 8.2% blende and lead. A. M. Gaines is in charge.

QUAPAW.—Kentex Mining Co. contemplates erection of mining and milling plant costing \$100,000. S. C. Kennedy is manager.

Lucky Joe Mining Co. is erecting a 250-ton mill near Quapaw. J. P. Matthews is manager.

OREGON

Geology of the Oregon Cascades is summarized by Warren DuPre Smith in Bulletin 16 of the University of Oregon, at Eugene. Geological history of California and Oregon are considered to be much the same. In the metamorphic rocks is serpentine, carrying chrome ore, also some nickel and copper. In the younger sediments is a fine diatomaceous earth. The recent gravel areas have yielded some of the best gold by placer operations. These are the most important economic points in the publication.

GOLD HILL.—Decision of considerable importance to miners in this region was given this week at the United States Land Office at Roseburg, in a contest for Government land, between J. H. Beeman and E. J. Jamison. Judgment was in favor of Beeman, the mineral claimant, and against Jamison, the agricultural claimant. Several years ago Jamison located a homestead of 160 acres on Government land, which includes the quarry tract selected for the State limestone plant at Gold Hill. Later, Beeman and others discovered the lime deposits on the homestead, and located three claims of 60 acres thereon; and on the recent application of Jamison for a patent for his homestead, Beeman filed a contest, claiming the land more valuable for mineral than agricultural purposes. The decree gives Jamison a patent for the homestead, saving and excepting the mineral land of 60 acres, which is given to Beeman.

MEFORSD.—Lee Devenport of Portland has arrived here with oil-drilling machinery to exploit the recently reported discovery of asphaltum deposits east of Ashland, in the hills at the head of Antelope valley. It appears that large deposits of high-grade asphaltum have been uncovered in carbonaceous shale, with evidences of petroleum.

UTAH

ALTA.—Cottonwood district continues busy. Columbus Rexall has 800 to 1000 tons of ore broken; Emma is shipping a carload daily; Michigan-Utah is soon to start shipments; while Sells and South Hecla are sending out ore. Snow is deep, but roads are good.

BINGHAM.—Utah Metals & Tunnel Co. has suspended ore shipments until lead prices improve. All properties of this company are opening well.

EURKE.—Railroad may be constructed to West Tintic and Erickson districts. The Salt Lake, Fillmore & Kanosh Railroad has been organized with capital of \$500,000, mostly by Provo people. G. W. Craig of the Salt Lake Route is president. It is intended to build a standard-gauge, single-track line from Lyndyl south-east to Kanosh, by way of Holden, Fillmore, and Meadow, a distance of 50 miles. In addition, a 25-mile branch to north-west of Lyndyl, taking in the West Tintic district. Both of these branches will be valuable feeders for the Salt Lake Route.

DUGWAY.—This district was recently examined by Pierre Peugeot, consulting engineer to the Dugway Smelting Co. Dugway Bertha has 200 tons good ore on dump, and is mining more. Luck Star development is good. Piedmont shows copper in 15 openings; also some bismuth at depth of 220 ft. Hidden Treasure has 6 ft. of 5% copper ore, and can supply 5 tons daily to smelter. Dugway Mining Co. can furnish 10 tons. Belcher claims are considered especially promising.

TINTIC.—Iron Blossom Con. Mining Co. reports for year ended November 30, 1917, ore sales worth \$526,909 on company account and \$67,854 from lessees. Operations cost \$357,874. Dividends absorbed \$259,000. Balance at beginning of year was \$224,315, and ended with \$148,995. Leasing has been adopted for most of the mine, on the following basis:

Value per ton	Royalty, per cent
Up to \$10.....	20
\$10 to \$15.....	25
\$15 to \$20.....	30
\$20 to \$25.....	35
\$25 to \$30.....	40
\$30 and up.....	50

WASHINGTON

CHEWELAH.—Northwest Magnesite Co. has suspended mining and calcining ore indefinitely. About 100 men will be out of work.

KETTLE FALLS.—Ark Mining & Milling Co. of British Columbia has been reorganized as the Ark Mines Co. of Washington to operate the Silver Queen claims three miles south of this place. J. J. Budd is president.

LOON LAKE.—Loon Lake Copper Co. has developed considerable ore to depth of 500 ft., and is to issue bonds for \$40,000 to construct a mill, etc. Flotation and fine grinding machines are to be included. Profit in sight is estimated at \$150,000. C. J. Stone is in charge.

ORVILLE.—Hudson Consolidated Mines Co., formerly Owasco, has made financial arrangement to erect 150-ton ball-mill and flotation plant costing \$75,000. Ore-reserves said to be 50,000 tons of smelting grade, and 100,000 tons for the mill, latter to give \$2 per ton profit. A. E. Wilson is in charge.

REPUBLIC.—Frank Babcock, of Ewan, has purchased the Belcher property here for \$50,000, payable in instalments over a period of two years. Last year the Belcher shipped 3000 tons of low-grade copper-gold ore, carrying 6% copper and \$1 in gold. Some 5000 ft. of development has been done.

WISCONSIN

PLATTEVILLE.—Better conditions prevailed in the zinc region in the first week of March. Although markets were dull, ore production improved, gross yield being 4525 tons, and net to smelters 2200 tons. Increased output, however, is not for ore-dressing plants, and a big reserve is on hand in the field. There has been a falling-off in shipment of high-grade product to smelters. Deliveries of low-grade ore have been slow, and reserves are piling-up. Stocks of lead ore are from 1500 to 2000 tons, only 5 carloads leaving the field during week ended March 5. Demand for pyrite improved. One concern is said to have over 5000 tons on hand. Hercules Mining Co., with capital of \$100,000, has been organized at Cuba City to develop 400 acres on farms 2½ miles from that place. Drills cut high-grade zinc ore. Shaft is being sunk, and mill is to be erected in spring.

WYOMING

LANDER.—Asbestos in considerable quantity has been developed 25 miles south of this place by the American Fireproofing & Mining Co. Seams vary from knife-blade to 1½ in. thick. Two carloads were shipped some time ago. Lack of funds and facilities has hindered operations, according to the secretary, S. E. Collyer.

CANADA

ALBERTA

BANFF.—Silver-lead ore valued at from \$148 to \$182 per ton has been discovered in the Rockies near this place by Michael Penrose, who is employed by the Calgary Copper, Limited. The find is on the site of the deserted camp of Silver City, which,

30 years ago, had a population of 2000 people, most of them prospecting for this same silver vein. The ground now belongs to this company which was granted prospecting and mining rights before the order prohibiting prospecting in the Rocky Mountains Park was issued by the Dominion. This is the first discovery of galena of this kind in Alberta. Already 1000 sacks of ore are stacked at the mouth of the mine awaiting shipment, and the Calgary company is making arrangements for developing the property on a large scale.

BRITISH COLUMBIA

COPPER MOUNTAIN.—The Canada Copper Corporation is driving a tunnel to open ore at a depth of 1000 ft. below the highest outcrop. Work was started in October 1917, and on January 31 the opening was 2067 ft. long. Present advance is 18 ft. daily, including timbering. The tunnel will be connected with the upper workings by a raise 720 ft. long. The smelter at Greenwood is receiving 700 tons of ore daily. On account of coke shortage only one furnace is in blast.

SALMO.—Hudson Bay Zinc Co., on 300-ft. level, has opened ore 40 ft. wide. According to manager, M. W. Bacon, 400,000 tons should be developed.

SLOCAN LAKE.—Eastern British Columbia mining companies are not experiencing any water shortage this year—an unusual condition. As a result, preparations have been made to resume milling at a number of properties. By the end of February nearly every plant near Slocan Lake will be in operation.

ONTARIO

COBALT.—Wetlaufer-Lorrain Silver Mines reports for 1917 that from February 17, 1916, to September 1, 1917, the property was idle, since when the Pittsburg Lorrain Syndicate has been a lessee. No royalties were received. Surplus at end of 1916 was \$129,152, and at end of 1917, \$112,642.

Crown Reserve company may relinquish its interest in the Newray mine at Porcupine.

Nipissing Mines Co. produced in January silver valued at \$307,019. Mills treated 6449 tons of ore, of which 53 tons was high grade. Shipments of bullion during January including custom metal were valued at \$310,881. In December Nipissing produced silver valued at \$340,793 and shipments totaled \$376,433. No new veins were discovered in January. Diamond-drilling is under way in diabase in claim 407.

The Crown Reserve has installed a mining plant on the Walsh property in the Gowganda field, and is conducting extensive exploration. A number of promising veins has been discovered on the surface.

Ore from the Pittsburg-Lorrain mine, in South Lorrain, is being treated at the Wetlaufer mill, now under lease to the company. Cross-cutting on No. 3 and 4 levels is under way.

Sampling of the Hudson Bay has indicated the occurrence of a large quantity of low-grade ore, which, under present conditions, can be profitably treated.

The Mining Corporation of Canada is making good progress with the development of its gold claims in Rickard township. The mining plant has been erected and put in operation. A shaft is being sunk on the main vein, which has been uncovered for a distance of 500 feet.

CONISTON.—Alexo nickel mine at Porquios Junction, 30 miles east of Porcupine, produced 812 tons of ore in January. This was a record output. Mond Nickel Co. treats the ore.

KIRKLAND LAKE.—Companies in this district may have a geological examination made.

Mine managers and officials of Temiskaming & Northern Ontario railroad have conferred on the branch line to be constructed from Swastika to this goldfield.

KOREA

UNSAN.—Oriental Consolidated in October treated 26,174 tons of ore yielding gold valued at \$124,065, of which \$47,790 was profit.

MEXICO

CHIHUAHUA

CHIHUAHUA.—Another effort will be made by the American Smelting & Refining Co. to operate its smelter at Chihuahua, according to advice received at Monterrey by officials of that company. It is stated that a large number of American employees recently assembled at El Paso for the purpose of

NORTH-WEST AND CENTRAL MEXICO

proceeding to Chihuahua to re-open the plant. These men were provided with passports, but their crossing into Mexico has been delayed on account of a revival of bandit conditions immediately to the south of Chihuahua. It is planned, however, to send these men to Chihuahua soon, and it is expected that the smelter will be started early in March. It is stated that an ample supply of coke is on hand to keep the plant running for some time. Ore shipments from the Santa Eulalia and other districts of Chihuahua have been arriving at the smelter for several weeks past. It was the announced intention of the American Smelting & Refining Co. to also re-open its smelter at Velardeña, State of Durango, at the same time as the plant at Chihuahua, but disturbed conditions near Velardeña make that plan practically hopeless, for the present, at least.

Mines Company of America directors met in New York in January to consider re-opening its mines in Chihuahua and Sonora, but took no action.

DURANGO

MAZATLÁN.—Power-plant of National Mines & Smelters Co.,

was dynamited by Villistas on March 4. Two men were killed, but all Americans escaped.

MEXICO

MEXICO CITY.—Recent changes in export duty on ores and metals are of importance, according to a Consular Report to Washington, D. C. On December 13, 1917, it was decided to double export duties on gold and silver, thereby making rates 10% ad valorem on bullion, and 14% ad valorem on ores and concentrates, but these increases were apparently never put in force, as the monthly schedule of taxes for February 1918 shows about the same level as heretofore. On January 22, 1918, however, a decree was issued reducing to 1% ad valorem export duty on zinc in the form of ore, concentrate, or bars, the duty on other ores remaining 3% ad valorem. More recently duty on graphite has been reduced to 1.3% ad valorem. Reduction in duty on zinc was found necessary by reason of decrease in price in the United States. An order had previously been issued to facilitate exportation of zinc before the assay had been completed. By a decree of December 14, 1917, export duties were placed on iron and steel bars, wire, ingots, structural shapes, railway material, beams, and other forms, previously free of duty. At the same time, exportation of iron and steel manufactures, cables, pipe, and machinery was prohibited, except with the permission of the Treasury Department.

Bank of the Republic of Mexico with capital of \$20,000,000 (U. S. currency), which, it is stated, will eventually be raised to \$100,000,000, will open branch in Equitable building, New York, April 1. Under new Mexican currency system it will be only bank permitted to issue paper money, such money to be backed by gold reserves. Dr. Caturegli, American financial agent of Mexico, says statement that Mexico will borrow \$15,000,000 gold is inaccurate. Arrangement provides for payment in gold of purchases of Mexican products, that is, silver, copper, oil, etc.

SONORA

DOUGLAS, ARIZONA.—Mineral exports from Mexico during January totaled 341 carloads, valued at \$2,878,200, compared with 317 in December, valued at \$2,785,000. Of the total of 13,347 tons, the Nacozari district contributed 11,286 tons; El Tigre, 219; Estrella, 782; Promontorio, 299; Archipelago, 104; Belen, 113; Bella Union, 89; and Ultima Chanza, 72 tons. The Jupiter, La Caridad, La Fortuna, San Julian, San Pablo, San Francisco, La Cruz, San Ignacio, Mexico, Las Chispas, Lillie, Santa Rosa, Cuicula, La Reforma, and Esperanza shipped one car each, equal to 383 tons.

Shipments from Nacozari consisted mostly of copper-silver concentrate from the Motezumeta Copper Co., which were sent to the Copper Queen smelter at Douglas.

American Smelting & Refining Co. is operating three smelters in Mexico, namely, at Aguas Calientes, Matehuala, and Monterrey; but only at 35% capacity.

CANANEA.—This centre is busy, and a brief visit reveals the following situation:

Labor situation has been somewhat acute, owing to the large demand for men occasioned by resumption of work by Cananea Consolidated Copper Co., but conditions are rapidly becoming normal, and Mexican labor is flocking to the town.

Greene Cananea—Cananea Consolidated—is operating its smelter and rapidly getting its mines into shape for maximum production.

Democrata company, which has been operating regularly for past four years, is employing 900 men, and producing 900,000 lb. of copper per month. The new De La Vergne powerplant is ready for operation.

Calumet & Sonora company is operating its mine and mill and shipping zinc concentrate to the United States. This company is about to install a new Huff electrostatic plant for separation of zinc from copper ore.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

F. L. SIZER has returned from Merced, California.

GEORGE E. FARISH is here on his way to Salvador.

R. E. ADAMS has returned to El Paso, Texas, from Matehuala, Mexico.

D. C. JACKLING returned to San Francisco to be present at the flotation trial.

D. M. RIORBAN has gone to New York, expecting to return to San Francisco in April.

W. F. B. BERGER, lately in Colorado, has an office in the Balboa Bldg., San Francisco.

H. HAMADA, chief metallurgist of the Kuhara Mining Co., of Japan, is in San Francisco.

R. B. YERXA, metallurgist to the Miami Copper Co., was present at the flotation appeal.

ALBERT BURCH is examining manganese supplies in the West Indies for the U. S. Bureau of Mines.

RICHARD L. GRIDER, of the University of Kansas, is at Rochester, Nevada, examining mines.

ALF. TELLAM and E. C. TEMPLETON have arrived from the Altai, Siberia, on their way to London.

F. E. BROWNE has been appointed to the U. S. Government Smokeless Plants, under D. C. Jackling.

POPE YEATMAN has been commissioned Lieutenant-Colonel in the Engineer Corps of the National Army.

L. B. HARRISON, superintendent of Monterrey smelter of A. S. & R. Co., Mexico, is now at San Antonio, Texas.

C. F. KELLY, vice-president of the Anaconda company, has been elected a director of the Inspiration Consolidated.

JAMES L. BRUCE, manager for Butte & Superior Mining Co., was in San Francisco this week and is now at Los Angeles.

N. BRUCE MACKELVIE, president of the Butte & Superior Mining Co., has been in attendance at the flotation trial in San Francisco.

J. G. DICKENSON, manager of the O'Brien mine, Cobalt, and Miller Lake O'Brien mines, Gowganda, Ontario, has returned to Cobalt from a six weeks visit to the company's properties in Arizona.

GUY C. RIDDELL has returned to New York, after having spent over a year with the Broken Hill Associated Smelters in Australia. He has been appointed special expert on metals by the U. S. Tariff Commission.

Nevada Mine Owners' Association at Reno has elected the following: J. W. HUTCHINSON of Goldfield, president; W. H. BLACKBURN of Tonopah, first vice-president; L. V. JENKINS of McGill, second vice-president; and HENRY M. RIVES, secretary.

W. S. BOYD, formerly superintendent of mines for Ray Consolidated, has been appointed assistant general manager, succeeded as mine superintendent by G. A. SMITH, formerly assistant, his former position in turn being taken by E. A. Thornton.

U. S. CIVIL SERVICE COMMISSION announces open competitive examinations for metallurgical chemists, salaries \$1600 to \$2400 per year, and assistants thereto at \$1000 to \$1600. Applicants should apply at once for Form 1312, stating the title of the examination desired, to the Commission at Washington. On account of the urgent needs of the service, applications will be received until further notice.

AMERICAN CHEMICAL SOCIETY has decided to omit its St. Louis meeting in April. The annual meeting will be held at Cleveland, Ohio, in September.

METAL PRICES

San Francisco, March 12

Aluminum-dust (100-lb lots), per pound	\$1.00
Aluminum-dust (ton lots), per pound	\$0.90
Antimony, cents per pound	15.50
Antimony (wholesale), cents per pound	13.60
Electrolytic copper, cents per pound, in carload lots	23.50
Electrolytic copper, cents per pound, in small quantities	24.67
Dig-lead, cents per pound	9.50
Platinum, soft and hard metal, respectively, per ounce	\$108— 115
Quicksilver, per flask of 75 lb.	\$115
Spelter, cents per pound	9.50
Zinc-dust cents per pound	17.50

Aluminum price has been fixed at a maximum base price of 32c, per lb for lots of 50 tons and over of ingots, 98 to 99% grade. Price is subject to revision June 1.

ORE PRICES

San Francisco, March 12

Antimony, 45% metal, per unit	\$1.10
Chromite, 34 to 40% free SiO ₂ , limit 8%, f.o.b. California, per unit, according to grade	\$0.60— 0.70
Chromite, 40% and over	\$0.90— 1.05
Magnetite, crude, per ton	\$8.00— 10.00
Tungsten, 60% WO ₃ , per unit	\$24.00
Molybdenite, per lb., 85% MoS ₂	\$2.15

Manganese prices quoted by the Miami Metals Co., South Chicago, Illinois, are as follows:

Manganese, %	Cents per unit
37 to 39	79
39 to 41	83
41 to 43	89
43 to 45	91
45 to 47	95
47 to 49	99
49 to 51	103
51 or over	107

These prices are f.o.b. cars South Chicago, and silica content must not exceed 15%. Penalty is 50c. per ton for each per cent silica over 8%, and bonus of 50c. for each under 8%. Settlement based on sample by Utah Ore Purchasing Co. at Murray, Utah.

Fluorspar is scarce at Eastern steel plants, on account of weather, labor, and transportation difficulties at the mines. The mineral is used as flux in basic open-hearth furnaces. Contracts for fluorspar in 1917 were \$3.70 per ton at mines, but those for 1918 have been made at \$2.5, with prompt delivery at present \$28 per ton. Kentucky and Illinois produce most of the ore, but Colorado has good deposits, and some has been mined in Arizona.

Chromite in the East is firm, with business having been done at \$1.50 per unit, delivered New Jersey, for a minimum of 43% Cr₂O₃.

EASTERN METAL MARKET

(By wire from New York)

March 12—Copper is quiet. Lead is steady and firm. Spelter is dull and lower. No quotations for platinum.

Silver in London was dull at end of February, according to Samuel Montagu & Co. The Shanghai exchange was inclined to be steady. Indian currency returns showed a further decrease in silver holdings, and were the lowest since November 11, 1913. Stocks in Shanghai on February 16 were 28,900,000 oz. in bars and 13,000,000 Mexican dollars.

Zinc ore at Joplin is steady at \$50 to \$65 per ton, basis 60% metal.

Eagle-Picher Lead Co. of Joplin, Missouri, reports sale of 250 tons of grade C spelter to Navy Department at 790c. per pound.

Butte & Superior in February produced 6250 tons spelter, 250,000 oz. silver, and made a recovery of 95%.

Spelter stocks in United States are estimated at 70,000 tons, an increase of 10,000 tons compared with February 1.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds

Quick-silver in London is quoted at £20 per flask, equal to \$96.

Wah Chang Mining & Smelting Co., Ltd. a corporation of China, desires to announce that the exclusive right to sell antimony, tin, tungsten, zinc, lead, and other products of the Wah Chang Mining & Smelting Co., Ltd., in the United States has been given the Wah Chang Trading Corporation, a corporation of the State of New York. It is expected that this change will offer opportunities for even better service to its customers.

Eastern Metal Market

New York, March 6.

All markets are bare of important news or features, and are generally quiet.

Copper is still somewhat scarce, but production is increasing. Tin is active for future delivery, but is unobtainable for spot. Lead is fairly active and firm.

Zinc is lifeless and lower.

Antimony is practically unchanged and dull.

Aluminum has been regulated by the Government.

The principle topic in the steel market is the question of a revision of prices after April 1. A meeting of representatives of nearly 75 steel companies was held in New York this last week. It was shown in many cases that costs had advanced to such an extent as to make higher prices necessary, particularly as to plates. It is understood that this was not true of the U. S. Steel Corporation and some of the large independent companies. Cost-sheets are being prepared, and the matter will be discussed at Washington, probably during the third week of March. Pig-Iron output in February was 5000 tons per day in excess of January, or 82,835 tons against 77,799 tons per day in January. It is not expected now that the 1918 output will equal that of 1917.

COPPER

Production figures for February are being watched with interest. Those so far reported show a higher relative output than in January, though this was under the same month a year ago. It is admitted that a scarcity, in this district at least, still exists, though it is not a serious one. It has caused some consumers anxiety recently, but reports are to the effect that no one has suffered. One large mill, which has both Government and other work, is really short of metal. The scarcity is a natural result of railroad congestion, severe winter, and other causes. Sales are being carefully regulated, the big buyer being, of course, the Government and its Allies. Producers are not inclined to commit themselves much beyond their present bookings until the situation is easier. All sales are made at the fixed prices of 23.50c. for wholesale and 24.67½c. for jobbing lots. February exports are estimated at 35,000 tons.

TIN

There is little to say about the tin market. It has been very quiet practically all of the past week, up to yesterday. On that day a fair business was done in futures, consisting of April and May shipments from the East, also in Banca tin. There is no average market quotation on these markets, each sale being a transaction by itself, subject to conditions pertaining to each case. There is no news as to permits or as to control of the market. As a whole the market is practically unchanged. Arrivals up to yesterday, March 5, inclusive, had been 385 tons, with the quantity afloat unreported. There has been but little change in the London market since last week. Yesterday the quotation for spot Straits was £319 5s. per ton, against £319 10s. a week ago.

LEAD

There are no special features. Considerable surprise can be detected in the trade over the Trust's advance in its price a week ago to 7.25c., New York, and satisfactory reasons are not given. It is generally conceded, however, that if the price should advance later to 7.50c. or above, the Government will step in and control the market as in copper. The market has been fairly active during the past week. Inquiry has been good and business has been done at 7.25c., New York, for shipment from the West. Lead for spot shipment has brought

7.50 to 7.75c., New York. All shipments from the West are subject to embargoes, and the buyer must assume the burden in each case. It is up to him to obtain permits.

ZINC

It seems to be impossible for the zinc market to show any signs of life. It has been more or less half dead for the greater part of a year. Production has been growing steadily less, but there still seems to be plenty of zinc to meet the demand, which is really light in proportion to the output. The market during the past week has grown weaker if anything, and prime Western is quoted at 7.62½c., St. Louis, and 7.87½c., New York, for early or March delivery. This has been shaded to 7.60c., St. Louis, on small sales, and it is stated that 7.50c., St. Louis, can be done. The 500 tons of grade C for the Government, referred to in last week's letter, has been awarded at 7.90c., New York basis. Spot zinc, prime Western grade, has sold as high as 8.25c., New York, in the last few days, but not in large quantities. Though considerable is held in New York for export, metal for spot delivery is scarce just now as the result of the railroad congestion. Grade A is quoted at 15c. per pound.

Sheet-zinc is available at the Government price of 15c. per pound, base, but it is a fact that the new list of extras calls for double the extra prices that obtained previously.

ANTIMONY

The market is unchanged at 13.50c., New York, duty paid, for Chinese and Japanese grades for prompt and early delivery, despite the fact that two 25-ton lots recently went at 13.25c., New York. No more seems to be available under 13.50 cents.

ALUMINUM

A fixed price of 32c. per pound has been placed on No. 1 virgin metal, 98 to 99% pure, by agreement between the War Industries Board and the producers. This contrasts with a previous price of 36 to 39c. which has prevailed for some time. The new price is to stand until June 1 and applies to nothing less than 50-ton lots. The status of smaller quantities remains unsettled.

ORES

Antimony: No developments are noted in the market.

Manganese: A new high record has been made in sales of manganese. A lot of high-grade Indian ore went to a large maker of ferro-manganese this week at \$1.35 per unit; the previous high was \$1.30 for this or any other ore. When the writer of these notes questioned about its making the alloy, an official of the Anaconda Copper Mining Co. in New York stated that there was nothing to be said about it at present.

Molybdenite: This is slightly lower at \$2.10 to \$2.15 per pound of MoS_2 in 85 to 90% concentrate. This is nominal, demand having been light.

Tungsten: Business is difficult, due to shipping embargoes, and prices are unchanged at \$20 to \$26 per unit, depending on grades with demand quiet. One dealer reports the placing of a large contract for wolframite at \$24 per unit in 60% concentrate. Ferro-tungsten is unchanged at \$2.25 to \$2.35 per pound of contained tungsten.

COPPER PRODUCTION of nine of the leading American mines—Anaconda, Chino, Inspiration, Miami, Nevada, Old Dominion, Phelps-Dodge, Ray, and Utah—for the first two months of 1918 total 173,707,000 lb., against 187,355,000 lb. in this period of 1917. Reduction is due to Inspiration not being up to capacity since the strike.

Company Reports

ST. JOSEPH LEAD CO.

PROPERTY: lead mines in south-east Missouri, producing over 8000 tons of ore daily.

OPERATING OFFICIALS: C. J. Adam, general manager at mines; W. A. Smith, manager of Herculeanum smelter.

FINANCIAL STATEMENT:

	1917	1916	1915	1914
Income	\$10,130,459	\$8,004,649	\$4,392,360	\$2,427,686
Depletion, etc....	4,520,186	3,330,182		
Charges			902,396	\$80,411

Balance	\$5,610,273	4,674,467	3,489,964	1,547,275
Dividends	3,535,531	1,409,466	854,980	258,391

Surplus	2,074,742	3,265,001	2,634,984	1,288,884
---------------	-----------	-----------	-----------	-----------

*Equal to \$3.98 per share on \$14,094,660 stock (\$10 par), compared with \$3.31 in 1916.

UNITED VERDE COPPER CO.

PROPERTY: copper mine at Jerome, Yavapai county, Arizona.

OPERATING OFFICIALS: C. W. Clark, general manager; R. E. Tally, assistant; T. Taylor, smelter superintendent; C. V. Hopkins, chief engineer.

FINANCIAL STATEMENT: revenue from metal sold was \$15,319,445. Investment account stands at \$12,339,503, a gain of \$4,934,981. Cash at end of 1917 amounted to \$1,958,528, against \$1,771,961 a year ago.

DIVIDENDS: in 1917 were \$17.25 per share, equal to \$5,175,000, against \$13.50 in 1916, \$6 in 1915, \$3.75 in 1914, and \$5.25 in 1913.

PRODUCTION:

	Copper, lb.	Silver, oz.	Gold, oz.
1917	71,726,634	1,223,311	29,230
1916	58,299,573	1,030,850	26,416
1915	45,127,832	902,880	28,221
1914	32,449,116	646,285	21,393
1913	35,333,924	641,626	20,664
1912	31,565,539	484,222	15,082
1911	33,166,987	461,145	15,239

Sales were 51,664,098 lb. copper at 27.30¢ per lb., \$75,451 oz. silver at 80.36¢ per oz., and 22,235 oz. gold at \$20.50 per oz. Remainder of the metal was carried in inventory, a new system for this company.

BRUNSWICK CONSOLIDATED GOLD MINING CO.

PROPERTY: gold mine near Grass Valley, California. In 1917, 440 acres adjoining were acquired, through which the Brunswick vein extends.

OPERATING OFFICIALS: R. Chester Turner, general manager; C. H. Mallen, superintendent.

FINANCIAL STATEMENT: during year ended January 21, 1918, revenue from bullion and concentrate totaled \$182,867. Balance from previous period was \$50,587. Including sundries, total revenue was \$239,185. Expenditure amounted to \$207,729, and balance carried forward was \$31,356.

DIVIDENDS: none was paid in 1917, and total remains at \$203,315, equal to 51¢ per share. Assessments to date amount to \$1.22 per share.

DEVELOPMENT: all work covered 1896 ft. in 1917, the new shaft being sunk 74 ft. This shaft was sunk to 1347 ft., cost being \$68.06 per foot in 1917. On 1300-ft. level gold is unevenly distributed in the east drift. At 1100 ft. the shoot is 700 ft. long, but stops over the western 300 ft. of this level extended only half way to 1000 ft., where the ore was of no value. Most important development was discovery of good ore in the 1100-ft. south cross-cut, being driven to prospect the Matteson

Ranch ground. A new electric hoist is needed for deeper work. Reserves are estimated at 10,000 tons.

PRODUCTION: two stamp-mills crushed 30,805 tons of ore, yielding \$1.965 per ton by amalgamation and 95.3¢ by concentration, a total of \$5.924 per ton, equal to a recovery of 75.8 and 14.6% respectively. Total since 1893 is \$1,765,361.

COSTS: including operating and administration charges, totaled \$6.2616 per ton. Mining accounted for \$1.3171, milling, 91.03¢; new shaft, 16.35¢; repairs, 6.92¢; improvements, 13.29¢; and general, 66.66 cents.

CHIEF CONSOLIDATED MINING CO.

PROPERTY: lead-zinc-gold-silver claims at Eureka, Utah.

OPERATING OFFICIALS: Walter Fitch, general manager, Cecil Fitch, superintendent.

FINANCIAL STATEMENT: during year ended December 31, 1917, ore sales realized \$1,554,714. Balance on hand was \$477,295. Total receipts, including sundries, were \$2,057,811. Expenses were \$1,127,316 for operation, \$134,618 for new property, and \$43,682 for equipment. With \$159,000 of Liberty Bonds disbursements were \$1,385,995. Balance forward to 1918 is \$262,394.

DIVIDENDS: four paid in 1917 totaled \$309,452, making \$925,392 to date.

DEVELOPMENT: new openings totaled 20,276 ft. Between the 600 and 1850-ft. levels, work included development of existing orebodies and searching for others, commonly found in association. Below 1800 ft. is under water-level, and ore mined is rich. New ore-channel on this level steadily yielded lead-carbonate ore. Production in 1917 was principally from 700, 800, 1600, and 1800 feet.

PRODUCTION: shipments amounted to 59,950 tons, averaging 0.153 oz. gold, 25.6 oz. silver, 14.84% lead (11.92% in lead ore), and 20.29% zinc (36.16% in zinc ore). Gross value was \$40.12 per ton. Metal contents were 9175 oz. gold, 1,534,907 oz. silver, 10,816,710 lb. lead, and 690,747 lb. zinc.

COSTS: were \$18.80 per ton at the mine, and \$14.19 for freight, sampling, and smelting, a total of \$32.99. Deducting this from gross value, net profit was \$7.13 per ton.

UNITED VERDE EXTENSION MINING CO.

PROPERTY: copper mine at Jerome, Yavapai county, Arizona.

OPERATING OFFICIALS: George Kingdon, general manager; H. DeWitt Smith, superintendent.

FINANCIAL STATEMENT: past two years compare as follows:

	1917	1916
Gross sales of metal.....	\$14,583,649	\$9,949,919
Other revenue	171,465	31,154

Total	\$14,755,114	\$9,981,073
Expenditures, taxes, etc.....	6,496,997	3,042,872
Dividends	1,680,000	1,050,900
Surplus	6,578,117	5,888,101

DEVELOPMENT: openings totaled 12,206 ft., largely in connection with new shaft and adit. No new orebody was found. Reserves compare as follows

	1917	1916
Ore, tons	885,000	1,000,000
Copper, per cent.	14.5	16.0

PRODUCTION:

Ore, tons	115,064	80,159
Copper, per cent.	27.0	22.7
Silver, ounces	2.89	1.60
Gold, cents per ton.	29	64
Copper sold, pounds	58,239,636	36,402,972
Average price, cents ...	27.034	
Copper on hand, pounds.	20,860,622	
Cost per ton of ore.....	\$32.880	\$29.910
Cost per pound of copper.....	0.058	0.066

Recent Decisions

PLACER CLAIM—KNOWN LODES

Conveyance of a placer claim, under United States Revised Statutes Section 2320, includes all known veins and lodes of quartz within the boundaries of the claim.

Wilbur v. Everhardy (California), 167 Pacific, 861. September 17, 1917.

DUMPING TAILINGS ON ANOTHER'S LAND—LIABILITY

Where the managers in charge of the mining operations of a corporation, with knowledge of plaintiff's objections thereto, dumped tailings on plaintiff's land, they, as well as the corporation, were liable for damages.

Robinson v. Moark-Nemo. Consol. Min. Co. (Missouri), 196 South-Western, 1131. July 2, 1917.

SEVERANCE OF MINERALS—ADVERSE POSSESSION

Oil and gas are included as minerals in a reservation of "all mineral rights" in a deed. Where mineral rights have been severed by deed a possessor of the surface for agricultural purposes can acquire no adverse possession of mineral rights.

Barker v. Campbell-Ratcliff Land Co. (Oklahoma), 167 Pacific, 468. September 18, 1917.

COAL MINE—LIABILITY OF SURFACE OWNER FOR DAMAGE

The owner of the surface of coal lands, the mineral rights to which are owned by another, is liable for damages to that other for making openings in a stream bed which permitted water and sewage to flow into the mine being operated by the other beneath the lands in question for the extraction of coal therefrom.

Sorg v. Frederick (Pennsylvania), 100 Atlantic, 481.

OIL LEASE—VALIDITY OF EXTENSIONS

When a landowner execute an oil and gas lease and later grants two extensions thereon, and while the latter of these two extensions is in full force and effect executes a second lease on the property, the second lessee, if he has actual or constructive knowledge of the extensions of the first lease, acquires no rights under the second one.

Swan v. O'Bar (Oklahoma), 167 Pacific, 420. September 18, 1917.

MINING OPTION—STOCKHOLDERS' CONSPIRACY

A mining company having entered into an option agreement for the purchase of mining claims in Arizona, had difficulty in meeting payments under the option. Thereupon certain stockholders in the company secretly bought up the optionor's title and later entered into a re-organization plan with creditors. Held, no conspiracy to defraud was shown by the above acts of the stockholders, nor could the price fixed in the option contract be taken as any indication of the cash value of the property, since the only obligation upon the optionee was to forfeit payments already made if it desired to abandon the agreement.

Munro v. Smith (Rhode Island), 243 Federal, 654. July 13, 1917.

OIL LEASE—FORFEITURE DENIED

Where three persons execute an oil lease jointly, it cannot be forfeited upon a notice signed by but two of them. Where the lease requires such a notice to include an alternative demand for performance of conditions of which a breach is claimed, a notice to the lessee not containing such alternative demand is fatally defective. Where the lease also requires performance of assessment work on each claim prior to September 1 of each year, or forfeiture as to those claims upon

which such work is not performed, the lease will not be forfeited as to claims for which patents were secured by the lessee because of non-performance of annual labor on the unpatented claims.

Jameson v. Chanslor-Canfield Midway Oil Co. (California), 167 Pacific, 369. September 27, 1917.

MINING TRESPASS—PLAINTIFF'S POSSESSION

An action of trespass for the unlawful mining of coal could not be maintained where the plaintiff had never been in the actual or constructive possession of the surface which was in possession of parties holding adversely, and under whose lease defendant had removed the underlying coal, as plaintiffs, never having severed the coal, were not in constructive possession thereof.

Griffin v. Delaware & Hudson Co. (Pennsylvania), 101 Atlantic, 750.

Book Review

A TEXTBOOK OF INORGANIC CHEMISTRY. Edited by J. Newton Friend. Vol. IV. Aluminum and Its Congeners, Including Rare Earth Metals, by H. F. V. Little. Plates. III. Pp. 485. Name and subject-indexes. J. B. Lippincott Co., Philadelphia, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$5.

This is the third volume, issued to date, of the notable series of textbooks on inorganic chemistry constituting one of Griffin's scientific series. The scheme for a consistent orderly discussion of the subject was evolved by the editor, Dr. Friend, and assignments to specialists were then made. The authors have varied in their rapidity of work, so that the next to the last of the series, Vol. VII, was issued first, this being in 1915. It dealt with the halogens and their allies, and was prepared by Jeffry Martin, and E. A. Dancaster. It is one of the most satisfactory treatises on the halogens that has yet appeared, and is interesting and valuable for study as well as for use as a handbook. Vol. I, which is an introduction to modern inorganic chemistry by J. Newton Friend, H. F. V. Little, and W. E. S. Turner, is an admirable resume of the fundamental principles of chemistry, and is unexcelled as a reference book on the fundamentals of the science. It also deals with the chemistry of helium, neon, argon, krypton, xenon, and niton. It is thoroughly up-to-date in every particular, and the exposition is strikingly lucid and will be appreciated by students. Vol. III, which has now come to hand, also published in 1917, is particularly timely on account of its discussion of aluminum and the relations of this element to modern industry in the production of the metal, and in ceramics. There is also an interesting chapter on the production of ultramarine, which discusses the technique of the subject. In view of the interest in rare metals it is necessary to call attention to the fact that this volume deals with the rare-earth elements, and not with the rarer metals that have recently been arousing so much popular interest in connection with alloys. The elements discussed are gallium, indium, thallium, scandium, cerium, lanthanum, praseodymium, neodymium, samarium, europium, gadolinium, terbium, the yttrium group, and actinium and its disintegration products. The general characteristics, thermochemical properties, and general reactions of all of these metals are given in great detail, and the conditions under which the various salts and acids may be obtained are given with sufficient clearness so that any chemist would be able to obtain satisfactory results. It should also be mentioned that one chapter deals with boron, and that a discussion of the relations of the rare earth metals in the periodic series is given in the form of an introduction. These volumes should constitute part of every chemist's library.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

KRAUT FLOTATION MACHINE

This is an improvement on the well-known 'K & K' flotation machine, which has been on the market for about a year. In that short length of time it has gained a remarkable popularity. The principle employed in this latest type of machine is identical with that in use in the original 'K & K' apparatus,

The essential feature that differentiates this new apparatus from the older type, consists in the fact that it dispenses with the spitzkasten in front of the machine. Instead, there is a bubble-collecting chamber arranged on top, and a series of adjustable skimmers, as shown in the accompanying illustration. By means of these skimmers the bubbles carrying the mineral particles are removed from the rotating pulp almost as fast as they are made, collected in the collecting-chamber until there is a sufficient quantity to fill it to the top, and then made to overflow a discharge lip into a concentrate launder. The pulp entering at the bottom, at one end of the machine, is being rotated continually by the rotor, moving in a helical path toward the tailing-end of the machine, where it is finally discharged at the top of the machine after having surrendered its mineral contents.

The advantage over the previous types of K & K machines consists in the increased efficiency, combined with the reduced floor-space, which is about half that required by the older type, and, further, in the fact that no head-room is lost. On the contrary, head-room is gained, the tailing-discharge being 18 in. above the feed-intake. This renders it possible, when desired, to pass the tailing from one to another machine for re-treatment on the same floor-level. In operation, a distinguishing feature of this apparatus as compared with other flotation machines is, that there is no pulp-level, but at the point of contact with the skimmers there is a mixed zone of mineral carrying bubbles and pulp. As there is no pulp-level to be maintained, no regulation of such a pulp-level is necessary, and therefore it does away with any need of adjustment for accomplishing this object. A simple device at the tailing-end of the machine regulates the tailing-discharge automatically in such a way that it always equals the feed-intake in volume. Another adjustment makes it possible to control the amount of pulp held in the machine at any one time.

The entire mechanism will be built of steel and cast-iron, and will be placed on the market in a short time by the Southwestern Engineering Co. of Los Angeles.

retaining the rotor, consisting essentially of a hollow cylinder, the surface of which is provided with longitudinal riffls and air-spaces between them, through which the air is introduced into the pulp from the atmosphere, this entering as a result of the reduction in static pressure caused by the velocity or motion of a relatively thin layer of pulp adhering to and following the surface of the rotating cylinder. The air is entrapped between the riffls, and a thin film of pulp is drawn over it, causing the formation of bubbles to which the mineral particles adhere.

FLAT WALL-PAPERS now in popular use are composed of non-poisonous pigments and produce a water-proof surface which permits of washing, is impervious to dampness, and resists decay. On their hard non-absorbent surface there is not the slightest foothold for dust or germs. Through the use of flat wall-papers for interior decoration every surface in the home—floors, walls, and ceilings—may be fully exposed to the purify-

IMPROVED K & K FLOTATION MACHINE

ing effects of light, air, and sunshine. For kitchens and baths sanitary gloss paint is preferable, as it is even more easily cleaned. Paints are not only sanitary, but they are in themselves powerful disinfectants. Drying paints give off vapors containing formaldehyde, an antiseptic which is fatal to bacteria. In fact, painting is one of the most efficient means of destroying bacteria in rooms previously occupied by persons with contagious diseases. If the windows are kept closed for a short time after the painting is finished, every portion of the walls and ceiling, and the contents of the room, will be fumigated or disinfected. Government tests of painted and papered surfaces exposed to the same conditions have shown an enormous development of bacteria in wall paper, while the washings from the painted surface showed a practical absence of bacteria. From the standpoint of economy the flat wall-paints should appeal especially to the home owner. Their low cost, their ability to hide surfaces with a few coats, and their large spreading capacity, mean a great saving in first cost, while their exceptional wearing qualities ensure long and economical service. They flow on easily, without showing laps or brush marks. The general adoption of flat finishes in hospitals, hotels, and public buildings to secure effects and sanitation suggests use of these in the home.—Du Pont Magazine.

HELP TRANSPORTATION

The growing difficulties of freight transportation has induced the Associated Business Papers, Inc., New York, through their executive committee, to formulate a plan for definite practical co-operation by shippers to relieve terminal congestion and to keep freight moving. Neither the efficient control of Government bodies, nor the wisdom of the railroad men can solve the whole problem. A large part of the trouble is the local and short-haul difficulty, resting in congestion which extends back into the main arteries of transportation. Business men in all lines of endeavor should realize that they are not merely buyers of transportation, at a price per mile or per ton, but that adequate transportation service is absolutely necessary to the profits of business. At the present time interest charges on goods in transit frequently amount to more than double the cost of the transportation, while the cost of waste, due to inability to secure materials and to ship goods, runs into larger figures.

The Government having now assumed control of the railroads, and Director General McAdoo having surrounded himself with a staff of practical railroad operators; a National Highway Committee having been appointed with Roy D. Chapin, president of the Hudson Motor Car Co., as its head, with the Board of National Waterways Association working with the official committee on this problem, it is our recommendation that the matter will be best served by full co-operation with these governmental bodies. It is time to quit kicking about rules established to clear the tangle, and to co-operate in a whole-hearted and intelligent way.

It is recommended that the shipper should be urged to foster the following:

FOR IMPROVEMENT OF RAILROAD SERVICE

- (1) The provision of adequate rules to secure full efficiency.
- (2) To establish proper charges for freight and demurrage and enforce equitable rules for loading and unloading, shipping and packing.

FOR HIGHWAYS

- (1) Extension of paved highways.
- (2) Provision for keeping them open at all seasons.
- (3) Proper provision for their maintenance.

FOR WATERWAYS

- (1) Construction of barges and small tow-boats to provide for the adequate use of existing highways.

- (2) Provision for putting into shape existing waterways that had been allowed to become obsolete.

- (3) Provision for the extension of these waterways to correlate with the railroad system.

ASSISTING THE RAILROADS

- (1) Co-operate without hesitation; do not object to changes.
- (2) Load and unload promptly; do not wait for a convenient season.
- (3) Load to capacity.
- (4) Do not re-consign en route; decide upon the destination before the goods leave.
- (5) Pack securely and mark plainly.

AIDING THE HIGHWAYS

- (1) Make a survey of all incoming and outgoing freight handled within zones 10, 25, 50, or 75 miles from your city.
- (2) Ship all goods to be delivered within the above zones over the road by motor-trucks.
- (3) Demand that all goods to be shipped to merchants in your city, and originating within the zones mentioned, be delivered by motor-trucks.
- (4) Make a census of all motor-trucks in your town available for this work.
- (5) Take up with your local offices of the national express companies and your local haulage and express concerns as to how far they can extend their present delivery routes.
- (6) Select a committee of the best traffic managers of concerns in your city to lay out a detailed plan to suit your local conditions, and determine upon fair rates to be charged.
- (7) Arrange for a sufficient number of receiving platforms or warehouses where you can use horse wagons and motor-trucks up to 3-ton capacity to deliver and set down goods, leaving for the larger trucks the running between the main points in the zones. Do not try to make the trucks running overland between the main points do pick-ups and deliveries. It cuts down their efficiency and makes the maintenance of schedules impossible.
- (8) Put some trucks in the overland-haul work on definite leaving schedules so that goods can be delivered to the receiving platforms or warehouses in time to make up full loads to any given points.
- (9) Arrange a Return Loads Bureau. Arrange with the local telephone companies to give your regular telephone number to any inquirer asking for the Return Loads Bureau. Post notices in the offices of your merchants that you have established a Return Loads Bureau. Post similar notices in conspicuous places in the smaller towns and cities through which trucks, running to or from your city, will have to pass. This will enable your trucks, and those of private truck contractors, to quickly collect loads.
- (10) Bring pressure to bear upon your mayor and the governor, and then to your highway commissioners, to keep the main highways leading out of your city open during the remaining winter months.
- (11) Bring pressure to bear on the proper authorities to resume construction of main-line highways at the earliest possible moment this spring, and to maintain the roads throughout the year.

PROMOTING WATERWAY EFFICIENCY

- (1) Secure information upon transportation facilities on existing waterways covering short hauls.
- (2) Urge the movement for immediate production of barges for large canals to relieve the freight congestion.
- (3) Take up with the traffic manager of your business, and the traffic expert of the local chamber of commerce, the possibility of the use of waterways for any part of your freight movement, and arrange shipping plans accordingly.

EDITORIAL

WE take pleasure in publishing an article on the fixation of the price of silver by two representative mining engineers, Messrs. Emmet D. Boyle and Whitman Symmes. The senior author is Governor of the State of Nevada, the junior is superintendent of the Union Consolidated and other important mines on the Comstock; both were members of the committee of Western men that went to Washington recently to consult with the Department of the Interior in regard to the very question that they discuss in the article.

OWING to the exigencies of the War the British government has placed an embargo on the use of telegraphic codes. Among these is the code-book of the late Bedford McNeill, our friend and the friend of engineers all over the world. Mrs. McNeill writes to us asking for help in preserving the goodwill of her husband's life-work, and we are glad therefore to make a plea on her behalf to the profession, asking them to keep the code in mind and to use it whenever practicable, both because it is particularly serviceable for its avowed commercial purpose and because it perpetuates the memory of one of the kindest, most loyal-hearted, and most intelligent members of our profession.

NOT the least interesting feature of the recent flotation appeal in San Francisco was the opportunity given for ignorant sensationalism on the part of the daily press. For several days before the hearing our local newspapers had a lot to say about the '\$60,000,000 suit' and 'The Big Fight of the Jackling Interests.' Most of their statements were grossly inaccurate, of course, but when the hearing actually took place not a single reporter was present in the court-room. That, however, did not prevent the newspapers from publishing a description of the proceedings. These descriptions were the "delirious trimmings"—as the old lady phrased it—of journalism. The 'Evening Howl' stated that "a huge working model of the disputed patent had been set up, and the crowded room reeked with acid fumes and other odors incidental to the operation of mining machinery." The laboratory machines in the room were not touched until four days later and no experiments of any kind were made during the hearing. The same scribe asserted that the argument, set for one day, was to "consume several days before a

final decision can be handed down by the judges." The 'Morning Scream' reported that Mr. Williams "brought the gangue into Court for the first time during the session. The gangue is the soil and other non-valuable substances in the mixture of water and ore." The 'gangue' is also a group of ignorant young men that fabricate yarns that would disgrace a school-boy. Not one of the four papers gave the names of the three judges correctly. They all agreed in including Judge Gilbert, whose withdrawal from the hearing was significant. The treatment given by an irresponsible and ignorant press to an event so important and interesting is a striking example of inept journalism, the kind that flourishes under such men as De Young and Hearst.

THE Edisonian method of seeking a solution to a problem is to try everything. For example, when testing metallic salts in an effort to improve the storage battery, he set a corps of chemists to work experimenting with every salt that could be produced economically. Applying this all-inclusive method to the study of flotation likewise may disclose unexpected possibilities. A suggestive illustration is afforded by the results obtained by different experimenters working with alkaline chlorides. Messrs. M. H. Thornberry and H. T. Mann conducted an elaborate investigation at the Missouri School of Mines, employing a long list of chlorides, the results of which have just been published in 'Metallurgical & Chemical Engineering'. Their conclusion was distinctly unfavorable. With common salt the average extraction was 4% lower than without the addition of the reagent, but they followed the usual practice in using oils. Thus the fact was established that metallic chlorides with oils reduced the percentage of recovery, and yielded a leaner concentrate. Independently an experimenter in British Columbia, working close to the sea, and desiring, if possible, to employ sea-water in practical operation, made the discovery that the sea-water alone, without oil, was an efficient flotation agent. His remarkable results were published in our issue of February 2. Following the hint given by sea-water he tried simple solutions of sodium and magnesium chlorides. The common-salt solution, applied to an ore assaying 1.75% copper, yielded a concentrate containing 15.35% copper and left a residue impoverished to 0.07% copper. Plain sea-water, on the

same ore, gave a concentrate assaying 21.61% copper, and a tailing that held only 0.09%. These interesting tests reveal the importance of investigating every possibility, and of ascertaining the effects that may be produced by varying the conditions as well.

AMUSEMENT may be gained from the capitulation of business men, even of men of big business, to the man trained in the principles of business. The principles of business are known in academic circles as economics, and the business man has been accustomed to laugh at this science as 'theory,' just as a certain class of men, still cherishing the traditions of empiricism, have delighted in scoffing at the trained engineer and geologist. It has taken many years to win acknowledgment that the trained engineer has the advantage of working intelligently and taking the shorter cuts to obtain results through applying principles induced from multitudinous observations collected during the course of generations, while the 'rough-neck' blunders as soon as he exceeds the limits of safety that are defined by the scanty teachings of his individual experience. The business man is prone to assume lordly airs of superiority, because he makes a specialty of acquiring money, which gives him power, but the specialist, in the long run, surpasses the amateur in practical performance. The economist, for example, Mr. Irving Fisher of Yale University, would probably make as much money as Mr. Louis F. Swift, of meat-packing fame, should he devote his time and talent to it, and he would probably do it with less irritation to the sense of justice that rises perennially in the workingmen and in the general public despite their long habituation to commercial spoliation. Dr. Fisher, however, is too busy doing better things than the amassing of millions to be lured from his desk. Nevertheless, it is in no spirit of disparagement that we record the appointment, on a substantial salary, of Professor L. H. D. Weld, also of the Department of Economics at Yale, as economic advisor to Swift & Company as soon as it was noised abroad that Mr. Herbert C. Hoover would pay special attention to the economic side of food control and production. This recognition of merit was two-fold: first of all it showed a realization that the mining engineer, trained to do things scientifically, would apply scientific methods in the food administration, and in the second place it was a confession that the business man was weak on the side of the scientific direction of commerce: as long as it was a case of ruthless destruction of weaker competitors, of squeezing exorbitant profits from the public, and of hammering down the cost of labor, the academician could add no strength to his armor, but he needed help in dealing with a man who threatened to regulate industry in accordance with fundamental principles of right and justice. Notwithstanding this precaution, the packers seem to have blundered. The client that does not disclose everything to his attorney is apt to lose his case. The packers surreptitiously tried to defeat the operation of the new

system while employing a scientific economist to adjust them outwardly to its requirements.

IN the article on the Kompelter region appearing in our issue of March 2 two errors that would be detected by a careful reader. In estimating the number of acres to be exhausted in order to produce a given tonnage the words "per annum" were introduced by that little devil of perversity that sits on the index finger of typist or compositor—or author. "Per annum," like the flowers in the spring, "had nothing to do with the case." The other error was the omission of a zero. Obviously, if 200 acres were sold by Mr. McConnell for \$200,000, then the rate was \$1000—not \$100—per acre. Referring to the Indians and their relation to the local mining industry, we are glad to add a further note. Prior to the passage of the Act of Congress of March 2, 1895, the Quapaws in Ottawa county, Oklahoma, held 100,000 acres of land as a 'reservation.' Pursuant to the Act just mentioned 300 Indians were allotted their lands in severalty, each Indian receiving 240 acres, the remainder of the tract being sold and the proceeds divided among the members of the tribe. A few Indians belonging to other tribes received allotments, as did also a number of white men that had been adopted into the Quapaw tribe. By the terms of the Act these Indians received their lands in fee simple, with a restriction upon alienation for a period of 25 years. In accordance with the General Allotment Act of 1887, and later by an enactment made in 1890, all Indians that received lands by allotment became citizens of the United States. The Quapaws could not lease their lands prior to 1897, at which time Congress gave them the right to do so without supervision or control of any kind for a period of three years if for agricultural purposes and for ten years if for mining purposes, but it was provided that if, by reason of age or incompetence, the Indian allottee was unable to manage his land, then the Secretary of the Interior, through the resident Agent, might lease it for him. This is the only supervision that the Government retains over the land holdings of the Indians, but the Quapaws cannot sell their lands without the Government's consent. The Indian agent is Mr. Ira C. Deaver, who lives at Wyandotte, where the Government conducts a free Indian school for the Quapaws and for six other small tribes that have been allotted lands in Ottawa and Delaware counties. The Government, through this Agent, exercises no control over these Indians personally, nor over their property, except as to the restricted Indian lands. Only one-tenth of the Quapaws have been declared incompetent; the others transact their own business and lease their lands as they see fit. The restrictions upon allotted lands will expire in 1921, but the Government reserves the right to extend the period of restriction, if it believe any of the Indians to be incompetent. It is pleasant to note the participation of our aboriginal citizens in the profitable exploitation of at least a part of our mineral resources and to record the act of justice by which this has been accomplished.

The Flotation Appeal

In our last issue we described the hearing before the Court of Appeals in the case of Minerals Separation v. Butte & Superior. The argument lasted one day and immediately afterward Judge Ross returned to Los Angeles, so that the subsequent proceedings did not take place technically before the Court. It appears, however, that the two other judges, who, unlike Judge Ross, did not sit in the Hyde case, and to whom the technology of the flotation process was new, expressed a wish to see the moving-picture demonstration that the Minerals Separation experts had prepared. So, on the Saturday evening following the Friday on which the argument had been heard, an upstairs room in the Rialto theatre was used for the purpose and a number of people were invited, including the two judges who remained in San Francisco and the counsel engaged in the case on both sides. The moving pictures included some of those used in the Miami trial, showing the action of individual bubbles on particles of mineral, oiled and unoled. The making of froth by propeller-mixers, and enlarged views of the structure of froths, were likewise shown, but some of these must have been confusing—to the two learned judges, for example—because the froth pictures showed the effect of currents of air passing upward, although they followed immediately after the pictures of the propeller-mixing, to which they were in no way related. Indeed, to anyone that has seen, for instance, the moving picture of a man coming forward with his own head on a charger, it is not necessary to suggest that a cinematograph does not supply trustworthy evidence on a scientific subject. However, the show was interesting, and it was conducted in such a way as not to offend the opponents of Minerals Separation. The flickering was trying to the eyes and we were glad that the performance was short. On the Monday following, in the morning, a series of experiments was performed in the court-room before Judge Morrow and Judge Hunt. Preceding the demonstration the lawyers engaged in a dispute as to the amount of oral explanation that was to accompany the experiments. Mr. Garrison suggested that, in the absence of Judge Ross, there should be no description or explanation of a controversial kind. Mr. Bull suggested that there should be no repetition of experiments illustrating the prior art, such as had been threshed out and set aside by the Supreme Court. Judge Hunt suggested that as each experiment was made the respective counsel should indicate to what phase of the case it applied. Mr. Garrison contended that to do so would involve controversy. Judge Hunt demurred. Mr. Garrison insisted that it would reopen the argument, now closed. Mr. Sheridan explained what happened before the Supreme Court, which asked for an explanation of parts of the experiments in order to elucidate the issue. Judge Morrow said that, in the absence of Judge Ross, it would be improper to have any argument; counsel might agree to read the description of the experiments as it appeared in the record before the Supreme Court. He had asked about the machines,

which he had seen in the room on the previous Friday, and when he had inquired why they were not used he had been told that there had been no time to do so. "We don't like the Supreme Court to get the best of us on information;" in patent cases, he said, the judges looked at the models left behind after a case had been heard and sometimes they attempted to work the models themselves—or tried to do it, unsuccessfully! Mr. Bull asked if his side might repeat one of the Minerals Separation experiments in a commercial machine, for comparison with the one that the other side made in a special bar-mixer. Messrs. Garrison and Williams protested that the proposed experiment was not in the record. Judge Morrow decided that the experiments must be performed under the limitations shown in the record. Counsel agreed. Appellant was allowed to say that a particular experiment was not made in a commercial machine. Here we may explain that the Butte & Superior people were anxious to show a froth-making experiment in a Janney machine using the coal-oil obtainable in the court-house, having made a test that proved that this mineral oil would make a good froth. The experiments were begun. First those for the Appellant were made by Messrs. Dosenbach and Engelmann, using Butte & Superior ore. They appeared to prove that a mineral-froth could be made first with 0.2% of pine-tar oil, and then with 1.62% of the same oil. Next a mixture containing 18% pine-oil, 12% kerosene, and 70% fuel-oil was used in the proportion of $1\frac{1}{2}\%$ on the ore, in a Janney machine. This oil-mixture is the one used in the Butte & Superior mill. The recovery, according to the record, was 98.09% in a concentrate containing 44.3% zinc. Only three experiments were made by the Appellant, and they seemed to afford the desired demonstration. Then came eight experiments by the Appellees. These were in charge of Messrs. Higgins and Chapman. First they made a vanning test on a batea, to show the principle of concentration by water. Next Carrie Everson's second method was illustrated by vanning a mixture of acidulated water, ore-pulp, and oil (17%). The oil-buoyed pulp overflowed from the batea, leaving a sandy tailing. The third experiment was made in a Kirby machine, to show what an abortive method he described and patented. The fourth showed the agitation-froth process of patent 835,120. It was performed with 0.1% oleic acid on ore from the Black Rock mine of the Butte & Superior company. A slide-Gabbett machine was used. After a good froth had been produced, an addition of oil, to 3.7%, was made in order to produce the Cattermole effect, namely, granulation. The fifth experiment showed the froth-making quality of phenol (carbolic acid) and illustrated patent 962,678, the one for a soluble frothing-agent. The sixth, seventh, and eighth experiments were watched with the keenest interest by all those present because by these experiments the Appellees undertook to prove that kerosene and fuel-oil do not produce a mineral-bearing froth. Several little bar-mixers, such as are used in preparing frothy drinks, were employed. These mixers are operated by a miniature electric motor and provide an in-

tensive stirring. Experiment No. 6 was made with Butte & Superior ore to which sulphuric acid and copper sulphate had been added in the proportions employed in the mill. The mixture was agitated for half a minute; then kerosene, in the proportion of two pounds per ton of ore, was added, and agitation for two minutes followed. The record, which was read by Mr. Williams, stated that no froth, only "three or four bubbles," appeared, but as a matter of fact the experiment, when made on this particular occasion, did show a considerable froth, whereat Judge Morrow cast a quizzical glance at Mr. Williams. Then the experiment was repeated with the addition of a little pine-oil, an increased froth resulting. Experiment No. 7 was of the same kind; a mixture of kerosene and fuel-oil in the proportion of 18 pounds per ton of ore was added to the acidulated ore-pulp and again a distinct black (mineralized) froth was apparent, although the record of the same experiment as made before the Supreme Court stated that only "a few bubbles" were to be seen. The addition of pine-oil, in the proportion of four pounds per ton of ore, was supposed greatly to increase the froth, but as performed on this occasion the increase was not as great as the record suggested. The experiments were too numerous and they must have confused the judges, neither of whom were versed in the technique. The unexpected production of considerable froth when experimenting with mineral oils must have been a disagreeable surprise to the Minerals Separation people. As a matter of fact some varieties of kerosene froth nicely, others do not. It is doubtful whether the failure to demonstrate the non-frothing character of mineral oils will be accepted as evidence by the judges, because they are supposed to decide the appeal on the evidence in the record, and the record says that the experiments yielded no froth. However, the judges will be led to question the value of the experiments as evidence on contentious points. The proceedings of that and the previous day suggested the advisability of having a special judiciary or commission to try patent cases. The controversy over the froth-making qualities of the different oils reminds us that Minerals Separation stumbled upon the fact that a vegetal oil was effective even in minute quantity as against the large quantities of heavy mineral oils used in the prior art, so that, in applying for their patent, they disguised the essential fact by a wide claim covering all oils. They used oleic acid, whereas their predecessors had used heavy petroleum. The factors that make one oil effective and another ineffective for frothing are not yet understood by the experts on either side. We suggested to Mr. Williams that a moving picture of the mineral-bearing froth made by plain seawater would be interesting, to which he replied that the litigation had not yet caught up with that. Of course not; the litigation has always been a whole lap behind, and that is why so much of it has had an air of unreality. The technology of flotation has progressed so rapidly that the records of the various suits have been more curious than informing. The patentees of 835,120 knew precious little about the underlying principles of

the process when they prepared their claims, and that is why they have had so much difficulty in applying them to current practice. We repeat what we have said before, that the opponents of Minerals Separation made a basic blunder in not demonstrating the practicability of the prior art, more particularly the Elmore vacuum method, instead of merely quoting it in rebuttal. The success of flotation in the mill is due largely to manipulative skill such as is covered by no patent and described in no book.

Metal Quotations

On our metal page each week we give quotations for ores and metals. For the former we give nominal prices, but for the latter the exact price. Occasionally we receive complaints—by letter and in person—saying that our quotations for ores are too low, or, for example, manganese, too high. It is most difficult to obtain current prices. Save in a few instances, ore-dealers or brokers hedge around in answering queries concerning prices; some refuse to divulge them. The West is not an extensive market for chrome, magnesite, manganese, molybdenum, tungsten, and other secondary ores, although they are mostly produced here. The markets are in the East, where these minerals are consumed. At the same time, Eastern manufacturers have agents or buyers in the West; but they are unwilling to give prices for publication, fearing perhaps that they might be bound by such, although names are not often published. We are independent of any influence in quoting prices, and will accept any schedule, provided it is from responsible firms. Something in the line of an ore clearing-house is needed in San Francisco, where buyers and producers can meet, also where sellers may ascertain the state of the market. The California Metal Producers' Association might be induced to help in this direction, as the business is important. In any case, it is impossible to give exact prices for ore, this being a matter of negotiation between dealer and producer, depending on analysis, situation of mine, and so forth. While on this subject it is apropos to mention that in the West are many deposits of low-grade chrome and manganese. The dressing of such ores to marketable commodity must be done some day, and it is pleasing to note that a start has been made. At several places in California and Oregon, chrome occurs disseminated as fine or large particles in serpentine. No amount of sorting would make such ore fit for sale, so concentration has been tried. In Canada and New Caledonia this has been done for several years. The same is true of manganese. We have personal knowledge of many Californian deposits high in silica that require dressing. At Crimora, in West Virginia, a large plant is extracting manganese from clay. At Butte, Montana, the Ophir mill of the Butte Copper & Zinc Co is dressing an ore carrying 23% manganese and 40% silica to 36% manganese and 10% silica, at a cost of \$1 per ton of ore treated.

Smelters' Charges

The Editor:

Sir—Your paper has always been progressive in its attitude toward the producer of raw materials and ready to help mend such matters where justice is withheld. We all have noticed that the mining situation, as regards the production of ores, is growing worse rather than better. It was thought the high prices would stimulate production both from the large producers as well as from the larger majority, that is, the small producers, and many are the reasons advanced for these difficulties that have ensued. I wish to bring forward one more, not that it is a new one, but I have not as yet seen it mentioned.

In 1916, the Mineral Farm property which is close to Ouray, Colorado, leased by myself and managed by C. R. Wilfry, a progressive mining engineer of this city, mined and milled 1209 tons of ore having an average assay of gold 0.028 oz., silver 6.31 oz., and lead 6.48%. The concentrate averaged gold 0.068 oz., silver 27.70 oz., lead 30.6% dry, iron 8.2, zinc 3.7, silica 27.8, sulphur 16.5%. The average prices and quotations for the metals were as follows:

Average quotation for silver per ounce, New York, in crude ore, 66½c., and of concentrate 70.406c.; lead per pound in crude ore 6.789c., and in concentrate 7.0206c. The average price paid per ounce for the silver was 95% of the quotation, and for the lead in crude ore 2.982c., and in concentrate 3.135c. These prices for 1916 represent 95% of the silver and 43% of the lead that the consumer paid, out of which we paid all mining charges, freight, and treatment. What becomes of the other 57%? Is it possible for any small producer to be successful on the above percentage of what he produces? I claim it is only possible should he be lucky enough to strike a body of high-grade ore that can be mined as cheaply as the low-grade, and that this percentage will not allow any one sufficient money to continue in the business.

Large mining companies, having extremely favorable contracts with the smelters, or those that are equipped with their own smelting and refining plants, can continue operating.

The prices in 1917 on lead, silver, and zinc ores, as long as the metal content is practically the same as that above given, and the zinc average is at least 40%, are now getting practically 50% of the price the consumer pays. Our Government desires that the mining of metalliferous ores be increased, because of the War, but, since mining expenses as a whole have increased approxi-

mately 67%, how can one do this if there is not something done with the only buyers of the ores to make them give the miner a larger proportion of what the consumer pays for the refined product?

I have taken this matter up with a senator from this State and he has turned over our correspondence to the Mining Bureau and the Attorney General, but there is not much hope that anything will be done unless the mining papers and the mining interests join to compel the authorities at Washington to secure better terms in the only market the producers have, the custom smelters.

H. C. BRANCH.

Ouray, Colorado, March 1.

Flotation Physics

The Editor:

Sir—In his recently published letter, your unknown correspondent, Mr. X, displays a familiarity with physics and electro-statics which is refreshing after reading Mr. Norris's dissertation on Greek history and nominalism. I am reminded by the latter of a conversation I had in Bisbee last summer with one of our American Bolsheviks (an I. W. W.). He summed up the creed of his organization concisely when he said, "If we can't all ride in autos, nobody'll ride in 'em."

To return to Mr. X, he suggests that our inability to float native metals may be due to the ease with which a film of oxide is formed on them. When ores containing sulphide minerals are ground dry, a film of this sort often forms, necessitating the use of more acid than usual. This acid, however, removes the film and allows the mineral to float. I can see no reason why acid should not also remove any such film from native metals. Further, many metals in an extremely fine state of subdivision will float; but to me this means that while the metal displays some adhesion to a bubble, this adhesion is not nearly so great as that of a sulphide mineral, of which much larger particles can be picked up.

I cannot quite agree with Mr. X that the combined charges in a particle of a conductor and in the electrolyte immediately surrounding it will sum up to zero. The phenomenon of electro-phoresis makes it appear that they would add up to a finite quantity in most cases. If the charges in a particle summed up to zero before it entered the electrolyte, the most probable alteration of its condition would be that some of its latent surface-charge would be conducted away to the exterior surface of the liquid, the electric condition of the particle be-

coming similar to that of other portions of the interior of the electrolyte, especially if the conductivity of the particle and the electrolyte were in any way equal. Such an hypothesis might explain the differences in electrophoric polarity I have observed and discussed several times.

I had no intention in my previous letter of implying that these latent surface-charges or other electric properties did not play an important part in flotation; I wished, principally, to draw attention to such portions of Mr. Stevens' argument as I thought were not entirely clear. I am still of the opinion, nevertheless, that until we can explain the failure of Coulomb's law at molecular distances, it is not safe to depend on it in explaining flotation, as the distance between a solid surface and the adjacent molecules in an adhering film is not large as compared with a molecule. There is evidence that there may be an electro-magnetic field associated with even a stationary electric charge, and it is by no means impossible that at close range these magnetic forces entirely supersede electro-static forces. I still intend to discuss at more length the bearings of our knowledge of chemistry on the affinities and adhesions observed in flotation, but have been so far prevented by ill health. Meanwhile I shall take the liberty of asking Mr. X, if he has not already done so, to read Dr. Langmuir's articles, which appeared in the *Journal of the American Chemical Society* for November 1916 and September 1917.

JAMES A. BLOCK.

Phoenix, Arizona, February 26.

Nickel-Copper Steel

The Editor:

Sir—I was much interested in James W. Neill's article on the magnetic separation of Sudbury copper-nickel ores published in your issue of the 23rd instant. It is a puzzle to me where H. P. McIntosh, secretary-treasurer of the Canadian Copper Co., could have got the sample of ore sent to Mr. Neill. At this time, 1891, the C. C. Co. was working three mines, Evans, Stobie, and Copper Cliff, and the ore from these mines, like that from nearly all the others except one, will not act in the way specified by Mr. Neill.

A fairly clean or self-fluxing ore such as is regularly mined in the district consists of pyrrhotite, pentlandite, and chalcopyrite, with 10 to 50% gangue, mostly norite. Such ore when picked fairly free from rock, crushed and separated with a hand magnet, will give a heading carrying the greater part of the iron and sulphur, that is, the pyrrhotite portion, but it will run lower in nickel than the ore before separation. If the ore before separation carries 3 to 4% nickel the magnetic heading will run about 2%, while the non-magnetic tailing will run higher, owing to the fact that the pentlandite is not lifted by a permanent magnet and pentlandite carries over 30% nickel.

For years I was in the Sudbury district and made

magnetic-separation tests on nearly every nickel ore in the district and some from outside, all of which, with one or two exceptions, acted as I state. The exception was ore from a small pocket, long since worked out, which was located between No. 2 mine and the McConnell of the C. C. Co. This ore acted as described by Mr. Neill and I took the mineral to be hazelwoodite. This ore was not touched till several years later than 1891 and it is not likely that Mr. McIntosh ever had a sample of it earlier than 1898. What is more interesting is the statement of Mr. Neill that he made these magnetic tests in 1890 or '91 and applied at that time for a nickel-steel patent based on magnetic separation of the copper-nickel ore. I struck the same idea about 1898 or '99 and was granted Canadian and U. S. patents on the process about 1900.

Edison was the first, to my knowledge, who ever attempted a magnetic separation of the Sudbury ores, but he was working on a separation of copper from nickel, and as he and the aforesaid Mr. McIntosh could not agree on terms, the matter was dropped. Sjöstedt of the Clergue interests was the first to attempt the actual manufacture of nickel-steel from Sudbury ore, but, as he depended on hand-picking to free the nickel ore from copper and gangue, the method failed. Enough ore to keep even a small blast-furnace running that could be successfully handled by this sorting method has not been found in the district. His tests were started about 1899.

In 1907 I suggested my method to Le Grand Smith, then of the Ventura Corporation, and about a year later, in connection with J. D. Hubbard, of the Chicago Exploration Co., they obtained picked ore from the Whistle and Mt. Nickel mines. This ore was mixed, roasted at the Sault plant of the Lake Superior Corporation, smelted into pig-iron in the electric ferro-silicon furnaces of the Electro Metals Co., at Welland, Ontario, then shipped to Syracuse, New York, and made into open-hearth steel by the Halcumb Steel Co. Several tons of this steel was made, and upon actual test it proved better steel than nickel-steel made in the regular way; in fact, it was a great success. But, unfortunately, like many other attempts to get capital interested in such a new and novel enterprise, this one was unfortunate. The method not only saves most of the iron and puts the sulphur in better shape to extract, but it also enables most of the cobalt to be saved—nearly all of which now goes to waste—and also saves the trifling amount of silver and platinum metals contained in the ore, besides saving more nickel and copper, especially on the low-grade ores, than is now recovered.

There are no metallurgical obstacles to the process, every step has been carried out successfully on a working scale, and no royalties stand in the way, for the patents have about expired. Yet more than a thousand tons of the very best iron—carrying no phosphorus—and about the same amount of sulphur, practically free from arsenic, goes to waste every day in the Sudbury district, squandering the resources of the province to no purpose

except to destroy vegetation, irritate the inhabitants, and breed lawsuits.

If there is any business in North America that needs hooverizing, it is the Sudbury nickel industry.

D. P. SHULER.

San Francisco, February 27.

Instruction for Prospectors

The Editor:

Sir—In your issue of the 16th ult., I note you favorably mention the short courses of instruction to prospectors given in the Mackay School of Mines at Reno, Nevada. Also, your comment that "this departure in the teaching of the art of mining is well worthy of commendation."

This well deserved credit to the enterprise of that school is not criticized, but I wonder why you note it as a "departure," for such courses of instruction have been given at the College of Mines in the University of Washington here in Seattle for many years. And by the way, with splendid success. The course has attracted a large number of the more enterprising mine-workmen from Alaska and north-western States who have embraced this opportunity to improve themselves. One of these men is now superintendent of one of the largest mines in Butte. He was a common mine-laborer, who had but limited educational advantages, but with sufficient enterprise to take advantage of this opportunity. The 'short-horns', as they have been affectionately termed at the school, have numbered as many as 100, but I understand the attendance is not more than half that this winter, because of conditions which you will readily understand.

MAURICE D. LEEHEY.

Seattle, March 5.

U. V. X. Bonanza

The Editor:

Sir—I have read with interest your article, 'The Story of the U. V. X. Bonanza,' in your issue of January 12. While, however, having no first-hand knowledge of the Jerome district, and approaching the subject simply from the standpoint of the student, I was struck by an apparent discrepancy between the geology as illustrated in the cross-section and in the accompanying text on page 47. In the cross-section there is certainly a suggestion that the older rocks, including the schist complex and intrusive quartz-porphry and andesite, had been eroded by weathering before the deposition of the sandstone; whereas, in the text, one infers that the quartz-porphry and andesite had been intruded after the deposition of the sandstone and limestone of Paleozoic age. The following quotation is from the article: "On the basement complex, after it had been deposited by weathering, there was deposited in late Cambrian times the sediment that now appears as beds of sandstone.

. . . This series of rocks underwent the movements incidental to the adjustment of the earth's crust. . . . Breaks were followed by intrusions of magma from underneath, forming more dikes and tongues of igneous rock. The substance of these was the felsite and quartz-porphry now exposed at the surface and underground."

I would desire to know which of these interpretations is correct.

A. G. BURROWS.

Toronto, February 26.

[The "more dikes and tongues of igneous rock" that penetrated the sedimentary rocks were later than those that intruded into the basement complex, but the section is wrong because it fails to show the later intrusives that cut through the sandstone and the limestone. We thank Mr. Burrows for drawing attention to the error.—EDITOR.]

Patents

The Editor:

Sir—In your editorials, on various occasions, you have at least implied that valid patents could or should not be obtainable for certain inventions, and I can only conclude that you or I must be laboring under some misapprehension.

The particular inventions referred to are those in which a minute quantity of oil is claimed in flotation, another in which, in the manufacture of electrolytic zinc, the use of manganese is claimed, and in a third case you doubt whether the use of sea-water in flotation is patentable. I do not profess to know the details of any of these processes and I can only deal with principles, but in my opinion, the validity of patents in each of these cases is unquestionable.

If it is the case that a minute quantity of oil gives a better result than a larger quantity, there certainly is discovery, and if a minute quantity had not previously been used by others, it would seem to me to be illogical to consider a patent for this discovery to be invalid. Any one who objects is quite at liberty to use the larger quantity of oil to which he had before been accustomed.

The second case is that in which you question the validity of a patent for the use of manganese in the electrolytic production of zinc, because some ores have already some manganese in their composition. I have not read the patent specification of this invention, but I have at times read various accounts of this process, which I hear is likely to revolutionize the zinc industry. My recollection is that the presence of manganese has certain peculiar and valuable effects, without which the electrolytic process for zinc had previously not been commercially feasible. If the patentee of this process has drawn his patent specification wisely, he will have claimed the use of manganese in the solution which he electrolyses, and then it will not matter to him from whence it is derived, whether it be from the ore or not. Quite apart from this, provided it can be proved that previous inventions were failures commercially, through

want of the knowledge of the functions of this manganese, the inventor is entitled to a valid patent.

Many efforts had previously been made, I understand, to electrolyze zinc, and it is rather unfair to the patentee that others should make use of his discovery and defraud him of his just rights, with the excuse that they cannot help this ingredient being present in their ores. It is common knowledge in this district that the company with the large mine to which you referred knew that they had manganese in their ores before they made their contract with the patentee, and after they thought they had learned from him all the details, they coolly threw him over. Conduct of this nature cannot be too strongly animadverted and I hope the offenders may be brought to book.

In the case of your doubt as to whether the use of sea-water in flotation can form the subject of a valid patent, again I should say, certainly, if it can be proved that no one was in the habit of previously using sea-water for that purpose. It is certain that had it been known that sea-water is efficacious, as you anticipate it may be, in flotation, some one or other would be using it to escape the rigid and onerous terms of the Minerals Separation Co. If it was not known previously, then the only recourse open to those who wish to make use of the discovery is to recognize the patentee and pay up.

I would like it to be distinctly understood that I have no practical acquaintance with any of the processes I have dealt with, and that I have only looked at the matter from what I consider to be a fair and commonsense viewpoint.

R. J. MUNDELL.

Vancouver, March 4.

Gold and Silver Standards

The Editor:

Sir—I have read with interest your editorial on 'Gold, Silver, and Credits' and your correspondents' letters in this connection. The subject of credit is at all times an obscure one and especially so now. Any bank-note makes inflation, and even the ordinary bank deposit and the individual check, which has a restricted circulation, is a species of inflated currency. For some reason or other, gold has been the standard of value for centuries. Now, the exchange-value of gold has been decreasing for some twenty years and there are minor fluctuations that do our nation harm. Quite likely the scientific unit is an honest day's labor of the unskilled laborer and the effort exerted in a given period by a given number of laborers and their equivalent in skilled laborers in the finding of gold mines and the winning of gold can be translated into gold. Thus it may be said that in this manner society gets its standard of value—gold—in an equivalent of men-days. Now here steps in applied science. Improvements in mining, in metallurgy, in geology have all tremendously cheapened gold production and measured in man-days gold is now far cheaper than in 1890. Moreover, banking facilities have been greatly improved and the flow of

money is so much faster that we have secondary inflation and expansion as a result.

Practically, a man wants money for its purchasing power. Therefore, if the dollar varies continually in purchasing power, it is like a yard-stick with a tremendous coefficient of expansion. Imagine the confusion resulting if women had to buy a yard of cloth for 75 cents on a warm day while on a cold day they would get only 30 inches. Yet just the same thing may occur with the monetary standard in a year's time. And much of the financial and industrial confusion can be laid to the varying intrinsic value of gold and the varying volume of credit based thereon, which causes the extrinsic value to vary.

Economists have long advocated a 'multiple' standard. Recently Professor Irving Fisher has been advocating as a standard of value a "full market-basket", which contains the average expenditure in goods of the average family, and that wages be paid, not in terms of dollars but in so many dollars as corrected by the price of commodities in the "full market-basket." Now, if it be true that we are drifting into a period of paternalism, and as paternalism reduces to a minimum unhealthy fluctuations in price, caused by sharp operations of the law of supply and demand by sharp people, some such scheme as Professor Fisher's might be made practical as a remedy for an unscientific and fluctuating standard of value.

Certain changes in society are sure to come. The evidence for this is the surprising number of conservative men who are discussing economic changes of a most astonishing character. When such men talk about things that a few years ago would have appalled them, it is certain that some of the schemes of the theoretical man and the visionary will be reduced to a working basis. Personally, I feel that we shall stop long before we reach a state of socialism or collective ownership and that we shall make popular certain old-fashioned virtues that were existent before the great influx of riches and ease, perfectly naturally, engendered in even the better class of men craft, cunning, and greed. Applied science has changed our life; science our ways of thinking. But human traits change very little in five hundred years. So, social changes may basically be not so radical as many people believe.

WOOLSEY MCA. JOHNSON.

New York, March 4.

PRIMARY aluminum made in the United States in 1917 was valued at \$45,882,000, an increase of \$11,982,000 over the value of that made in 1916. This increase appears to be due chiefly to an increase in the quantity of metal produced, but in part to an increase in the price of the metal.

ADVICES from official sources in Washington raise a doubt as to the availability of sufficient ammonia for refrigeration and ice-manufacture next summer. Consumers of ammonia will do well to give early consideration to the problem of obtaining the needed supply.

An American Policy Regarding Silver

By EMMET D. BOYLE and WHITMAN SYMMES

The situation of silver is paradoxical. The principal financial interests of the world contend that it is merely a commodity, and should be treated as such. When, however, China wanted to adopt a gold standard of coinage, pressure was brought to bear to compel her to retain silver as her money-metal. While vigorously advancing the doctrine that it is a mere commodity, these same financial interests deny to silver the right of free flowage in the markets of the world and they regulate it with monopolies, embargoes, and banking restrictions for the very reason that it is a money-metal.

In order to understand the silver situation it is necessary to appreciate how the interests involved are lined up. Silver production is an American industry. The principal Canadian and Mexican mines are owned in the United States. The British empire, except the Cobalt district, is not an important producer of silver. From the commodity standpoint, therefore, it is to the interest of the British to supply their requirements at as low a price as possible, and it is to the interest of the American producers to sell it for as high a price as possible.

Furthermore, in regard to its use as a money-metal, the British ideas are directly opposed to the American interests. Our economists have generally held that we are best off when the people with whom we deal are prosperous and have a large purchasing power. Great Britain, on the other hand, still clings to her old notion that it is better to keep the standard of silver as low as possible, in order that the British pound may buy goods in silver countries at comparatively low prices. The British think only of their own purchases, whereas it is American policy to consider the purchasing power of China and other nations with whom we desire to work up reciprocal trade.

Great Britain is the principal purchaser of silver, which she ships to India, 'the sink of the precious metals,' where it is used for coinage, for personal and other ornaments, and for hoarding; and she ships it also for distribution in the Orient through her marvelous system of exchange-banks. By maintaining a low price of silver Britain is able to purchase her Oriental goods at a more favorable rate of exchange.

The price of silver for the entire world is fixed in London by a group of four brokers known as the 'fixing board'. They operate under ancient Crown patents, a relic of medieval institutions, and all other people are prohibited from dealing in silver. There are no opening or closing bids, or high, low, or closing sales. One price is agreed upon for that particular day, and all silver changes hands at the price fixed.

Having fixed the price that their clients in London are

willing to pay, the brokers who compose the 'fixing board' monopoly generally telegraph to New York and make their purchases. The New York price follows the London price, less the cost of transportation, insurance, assay, and abrasion. Transportation is 2%, insurance has recently been 4%, assay is one shilling per bar, and abrasion is figured at one-fifth of 1%. The London price is in pence per troy ounce 925 fine, whereas the New York price is in cents per troy ounce 999 fine. The purchaser pays the London brokers' commission, which is one-eighth of 1%.

The only real rival to London as a silver-trading centre is San Francisco. In spite of the manifold controls that London exercises on the silver market through the fixing board, the Indian government, and the British-Oriental exchange-banks, silver continually finds its way from San Francisco to the Chinese market through non-British institutions. Moderate amounts of silver can always be sold in San Francisco for more than the London-made New York price, and occasionally, as has happened recently, San Francisco becomes a silver market all by itself.

To show how London is able to control the price of silver, a single instance will suffice. Last September the New York quotation was \$1.09½ and silver was being sold in large quantities at \$1.15¾. Great Britain then placed an embargo upon shipments of silver into and out of India, and allowed it to be handled only by the Indian mint. At that time there were orders on the New York market for ten million dollars worth of silver for shipment to the Orient. About two million dollars worth had been purchased when the British Oriental banks suddenly withdrew all exchange on New York. The purchasers were thus left with no way to pay for the silver already bought, so that they were forced to throw it back upon the market. These sales, the cancellation of the Chinese demand, and the closing of the Indian market, united to force the price down to 84½ cents.

More recently the United States was considering the payment of \$40,000,000 in silver to Japan for ships, but in order to hold the price down, Great Britain devised a way to cut out this demand. The British government borrowed 80,000,000 yen from Japan, and then applied this Japanese credit in New York as payment on one of her American loans. The net result is that the United States pays forty millions of the British loan instead of paying that amount to Japan, and Britain owes Japan forty millions instead of the United States owing it.

Great Britain desires to continue in control of the silver market for the following reasons:

First, to get cheap silver for her coinage in India, and

for other uses there. She has fixed the gold-exchange value of the Indian rupee corresponding to a silver value of 94.37c. per troy ounce, and by getting silver for less than that price the Indian mint has made a seignorage profit of \$51,000,000. If silver goes above that price, the Indian mint must lose, instead of profiting by its coinage, and if bullion were allowed to be shipped out of India a price above about \$1 per ounce would cover the costs of transportation, insurance, refining, and exchange, and would cause the rupee to disappear from circulation. It may be remarked that the Indian silver rupee is now also circulated in Mesopotamia and Egypt.

Second, to maintain a low price and therefore a favorable rate of exchange for her purposes in China. The Chinese tael is not a Government coin, but merely a weight of silver, and is equivalent to 1.2 troy ounces 931.5 fine. Britain would rather buy eight taels worth of goods in China for a pound sterling than only three taels worth.

Third, to control the Oriental trade. By being on the inside of the silver market Britain has been able to operate to the advantage of her own interests, and to the disadvantage of her rivals. The fluctuations in the price of silver may more than offset a fair commercial profit. One who has not actually lived in the Orient has little conception of the vast amount of daily speculation in silver and exchange. It is not only a common form of gambling, but it is a necessary part of every commercial transaction with a gold-standard country. With the British in control of the silver market, American firms have about as much chance to compete with the British as a lamb has to survive on Wall Street. This means that American firms must confine themselves to American specialties. Otherwise, sooner or later, the insiders will win.

Prior to our Civil War, the American tonnage on the oceans was almost as great as the British, and the Americans were a considerable factor in the Chinese trade. The last of the great American firms in China was Russell & Company of Canton, and they had a large number of steamers in the Chinese coastwise trade. About twenty years ago they sold their fleet and retired from business. On being asked the reason for this their manager replied, "If I were to name *one* reason I would say that it was the difficulty of handling the silver exchange." We have seen the price of silver fluctuate by 24% in the last few months, and the effect on a company that, for example, is handling a million dollars worth of silk and guesses wrong on the silver market needs no comment.

Fourth, to make profits from the Oriental exchange. All of the British Oriental banks are known as exchange-banks, and expect to make their principal profit, not from deposits and loans, but from exchange transactions. In an uncertain market naturally the charges are all the higher. Not long ago the price asked for exchange from New York to India was so great that Williams, Wignore & Co. refused to pay it. They found it profitable to

charter a ship and transport their own silver to India.

We should have an American policy in regard to silver, for the following reasons: First, to obtain an adequate remuneration for American labor and American investment, and for the wasting of our natural resources. It can be pointed out here that, in spite of the increased price for silver during the past year, profits have not increased, and the production of the State of Nevada in 1917 was 2,443,000 oz. less than in 1916.

Second, for the development and continued existence of an Oriental trade. As matters now stand it would appear to be necessary to establish efficient American banking agencies throughout the Orient, but if the price of silver is stabilized Americans could then safely use the established British banks until such time as American trade was developed to larger proportions.

The effect of a good and stable price for silver acts both directly and indirectly to assist the government of a silver-standard country. Last September, when silver was \$1.10 per ounce, the following letter was mailed to the London 'Times' from its special correspondent at Peking. "The advance in the price of silver, and the consequent rise in exchange have revolutionized the financial position of the government of China. The dollar today is practically worth double the average value before the War. Thus China, in meeting her heavy foreign obligations, has to provide only half the number of dollars that were previously needed. Meantime the salt revenue is greater than it has even been, while the maritime customs revenue, in spite of the restriction upon trade, maintains itself in a manner that is remarkable. The position is well illustrated by the circumstance that whereas the customs revenue used to be insufficient by some £1,000,000 annually to meet the Boxer indemnity and other payments secured on it, it is now carrying all these liabilities, together with the whole of the interest on the Reorganization Loan of £25,000,000, and up to the end of July there was, in addition, a surplus of about £2,000,000 available to the Government. There is, in fact, every reasonable chance that China, during the next two years, will have enough surplus funds to pay off outstanding debts, to redeem paper, and to standardize her silver coinage without borrowing a penny from abroad."

Last September Sir Rufus Isaacs, now Lord Reading, headed a mysterious mission to Washington. Thereupon the silver market became paralyzed. It was announced in Parliament that the British government was negotiating with the United States government for our entire output of silver. A little later it was rumored in London that the deal had been consummated, and that Lord Reading, who upon his return was rewarded with an earldom (the only Hebrew except Benjamin Disraeli ever to attain that dignity) had been thus honored because of his successful deal at Washington. Such, however, does not appear to be the fact, and it is much to be hoped that nothing of that sort will ever happen. We should maintain a distinctive American policy in regard

to silver, one that is in accord with our democratic principles. We should help Great Britain in every possible way in this war, but it is not necessary for us to assist her in maintaining a monopolistic relic of the special privileges of the Middle Ages such as the London 'fixing board.' Neither is it necessary for us to discriminate against our own silver producers and to subscribe to the doctrine of cheap silver which she so stubbornly adheres to.

We should fix a fair price for silver and we should stabilize that price. The natural demand for it is admittedly far in excess of any possible production, now or in the immediate future. There is at present no natural difficulty in evidence. India is prosperous and will absorb all the silver that is allowed to go thither. A fair price for silver will make China more prosperous, and the more prosperous it becomes the more silver it will want. The Chinese government voted to coin 150,000,000 oz. of silver, but has never been able to make the purchase. Of the entire world's production of 150,000,000 or more, only 110,000,000 oz. ever gets into the markets of the world. In the United States alone we use for the arts about 22,000,000 oz. of new silver per year. The amount of money involved in stabilizing the price, even under adverse conditions in the distant future, would never be great as compared with the results achieved. At present no money is required for that purpose, but the price of silver is 'stabilized' downward by various restrictions on its use. A fair price will do justice to our silver miners, encourage the development of business, and increase the purchasing power of the foreign nations with whom we desire in the future to deal. A stable price will decrease wasteful speculation and lay a safe foundation for our merchants during that critical time in the future when they are getting established in business with the silver-standard countries.

Our present one thought is the Great War. It may be said that the future for silver should wait. But war conditions and the consequent tremendous demand for silver have made the question a very present and a very live issue. The decision as to our policy should be made now.

THE EUREKA LILY MINE, in the Tintic district, Utah, a neighbor of the Tintic Standard on its western side, is getting ready for development immediately. A drift is being driven from the 1400-ft. level of the present shaft. The Eureka Bullion Mining Co. has a shaft already completed to the 600-ft. level. A hoist sufficient for work to a depth of 1000 ft. has been installed. The Iron King Mining Co. has resumed development, after having been idle for several years. Machinery is being placed for sinking a shaft to connect with the long tunnel that was completed some years ago. When this is finished the shaft will be below the tunnel-level and in the underlying limestone. At the Zuma property a winze started from the 500-ft. level has been sunk to a depth of 80 ft. It is proposed to continue driving on the 600-ft. level. New equipment has been ordered for the property.

Coal in Alaska

Acting under the Alaskan Coal Leasing law, the Interior Department is endeavoring as rapidly as possible to develop the coal resources of that country, with the idea that whatever production is obtained soon will not only be of valuable aid to Alaska but will also be a factor in winning the War. With a production of 50,000 tons in 1917 from the Matanuska field and the prospect that this output will be doubled this year, Secretary of the Interior Lane recently announced that 19,000 acres of coal land in the Nenana field are now ready for lease under the provisions of the leasing law. The coal land, which constitutes the most accessible part of the surveyed lands of the Nenana field, extend from the Nenana river up the valley of Lignite creek for 12 miles. The mouth of the creek is on the approved survey route of the Government railroad under construction between Fairbanks and Seward. The Alaskan Engineering Commission expects to complete the road from the Tanana river to these lands during the next summer and in this way furnish transportation for coal for barge-shipment to Fairbanks and other river towns. The Commission will also build a branch road up Lignite creek to bring the coal from the mines. The coal occurs in several thick beds, is easily mined, and is a lignite of fair grade. It is probable that it will be used chiefly for railroad, river-boat, and domestic fuel. This coal land is divided into 23 leasing blocks of 10 to 1664 acres. Applications to lease may be filed with the Commissioner of the General Land Office, Washington, up to March 1, 1918, or during the period of advertisement of the applications filed up to that date, which will be for a period of 30 days, beginning March 4, 1918. Applications may be filed for a single block, or for two or more contiguous blocks, the total area in a single lease not to be over 2560 acres.

OIL conservation has led to an investigation of water-power resources in the Pacific Coast States, and the following table shows present development of this source of power:

State	Minimum potential water-power	Practical development under present conditions	Installed capacity in operation
Arizona	893,000	280,000	33,700
California	3,424,000	1,100,000	731,000
Nevada	172,000	20,000	13,500
Oregon	3,148,000	950,000	176,800
Washington	4,928,000	1,200,000	333,600
Total	12,565,000	3,550,000	1,288,600

Steam-power installations in the Western States total 1,729,600 hp., of which nearly 50% is in California.

LATITUDE and longitude of nearly all important points in the United States can be ascertained with exactitude from Bulletins 216, 245, 310, 440, and 496 of the U. S. Geological Survey, to which the Director has again called particular attention.

Potash Prospects in Montana

By O. W. FREEMAN

It is believed that lakes have been located in central Montana which contain enough potash to make its extraction profitable at present prices. The gently rolling surface of the Great Plains east of the Rocky Mountains in Montana is broken by several small mountain uplifts. North of the Missouri river are the Bearpaw and Little Rocky mountains. South of the Missouri are the Highwood, Moceasin, Judith, Little Belt, Big Snowy, and other groups. The Bearpaw and Highwood mountains are mostly composed of lava flows. The others have been formed largely by folding, accompanied by laccolithic intrusions. A large number of dikes and several laccoliths are found in and near the Highwood mountains. These rocks have been studied in detail by L. V. Pirsson (U. S. G. S. Bulletin 237). He gives a considerable number of analyses of the igneous rocks, which he classifies as fergusonite (leucite), shonkinite, missourite, highwoodite, and others. Most of the analyses show that a high percentage of potash is present in these rocks; many average over 8% potash, while some contain as much as 11%. Pirsson estimates that the original intrusive magma contained 6.1% K_2O , which was increased in certain rocks by differentiation. Should methods be perfected to extract potash from complex silicates these rocks would prove a valuable resource. High-potash rocks also occur in the Judith, Bearpaw, and Little Rocky mountains.

The slow disintegration and decomposition of the high-potash rocks would liberate large amounts of it in soluble potash. It is believed that flood-waters would dissolve much of this potash, along with other alkaline salts, and carry them to undrained lakes and waterholes where they would be concentrated. Several lakes occur north of the Highwood mountains and close to the small towns of Geraldine, Montague, and Square Butte. These towns are stations on the Chicago, Milwaukee & St. Paul railroad, between Great Falls and Lewistown. The lakes cover a total area of many square miles, and are nearly all close to the railroad. The bedrock in this part of Montana is the Colorado shale, of Cretaceous age, which is impervious to water, and as the lakes have no outlet they disappear only by evaporation. Hence there has been a considerable concentration of alkaline salts. Some of the salts have been deposited as white incrustations around the lakes and in low areas that are covered temporarily by flood-water, but it is questionable if such deposits are of commercial importance. The water of several of the lakes has been analyzed. Some of the analyses are said to show over 7% potash in the alkaline salts of the lakes. Sodium chloride and sulphates are the most common salts present. It is doubtful if the salts that impregnate the soil about the lakes contain as much potash as the lakes themselves. Insufficient data have been secured to show whether the extraction of the potash

will be commercially profitable, but it is believed, by those who have investigated the matter, that there is enough potash in several of the lakes to permit its recovery at a profit, at least while the present high prices continue. Leases have been applied for that cover many thousand acres of Government land, including both the lakes and the soil impregnated with alkaline salts. Great Falls and Lewistown men are chiefly interested. Several sections of State land have also been leased. Development work will be continued, and if the results are favorable it is hoped to erect a plant near Geraldine for the extraction of potash next summer.

It is probable that a thorough testing of lakes elsewhere in Montana, especially in the northern part of the State, between the Milk and Missouri rivers, would show the presence of potash. It is doubtful if the potash content in any of the lakes of central Montana is high enough to make its extraction profitable at the low prices existing before the War, but it is thought that the industry offers a good chance for profits at the present time.

Handling Gasoline for a Mine Engine

Special care must be taken in handling gasoline. Most engines as purchased have fixed tanks into which the gasoline must be poured from the container in which it is brought into the mine. This arrangement is bad. More accidents with gasoline engines have resulted from a man carrying a naked light or smoking while filling such fixed tanks than from any other cause. In drawing gasoline, or in pouring it from one container into another, static electricity may be generated. It has been shown by experiments that unless the containers are grounded and are in electrical connection with each other, the accumulated electricity may discharge by a spark sufficiently strong to ignite the gasoline vapors. The use of portable tanks will entirely eliminate this danger. At the filling station the tanks should be connected electrically in order to prevent such accumulations. Cans with handles of wood or any other insulating material should never be used for handling gasoline. If a hose with a metal nozzle is used, a bare copper wire inside the hose and soldered to the nozzle and to the tank-connection will complete the circuit. If a can and a funnel are used, they may be attached to the tank with light copper or brass chain. The safest method of handling the gasoline for an underground engine is in a portable fuel tank. After the tank is filled on the surface, and all openings are closed, it is carried into the mine and connected directly to the fuel-line of the engine to serve as the fuel-supply tank. With this system it is not necessary to pour the gasoline from one vessel into another in the mine.—U. S. Bureau of Mines, Tech. Paper 174.

GOLD holdings of the United States on February 1, 1918, amounted to \$3,038,545,652, compared with \$2,912,465,116 a year ago. On August 1, 1914, holdings were \$1,887,270,664.

Drawing Pillars in Metal Mines

By W. R. CRANE

Constructive ingenuity coupled with experience has solved many of the difficult problems encountered in

veins is commonly spoken of as 'lifting' or 'picking up bottoms,' and consists in cutting out the ore in small

sections and the placing of stulls or square-sets as rapidly as possible. A filling of waste is not absolutely necessary provided the stopes above are not filled or are only partly filled. With filled stopes considerably more care is necessary and consequently more skill is required, although, as previously pointed out, the prime requisite is rapid and continuous work, when pillar-drawing is once under way.

FIG. 1. REMOVING ARCH-PILLARS UNDER FILLED STOPES, AUSTRALIAN PRACTICE.

metal mining, and not the least important of such problems is that of pillar-drawing.

The method of procedure adopted varies, of necessity, with the method of mining or stoping employed, as, for instance, where the ore is mined by ordinary overhand or underhand stoping methods and supports; or where caving is applied in the preliminary method of ore extraction. In order to provide against falls and therefore to make the workings as safe as possible during the mining of the pillars, it is desirable that the stopes should be filled with waste, which is added to as rapidly as space permits following the systematic removal of the pillars.

The essential considerations in the drawing of pillars regardless of how accomplished are: speed, continuous operation, systematic handling of ore and waste, and safety to men and mine.

Brief descriptions are given herewith of the drawings of the two principal forms of pillars, namely, the lateral pillars or the large unmined portions of ore temporarily left for protection between stopes and consequently running parallel with them and transversely across the lode or orebody, and top and bottom pillars or arch and floor pillars situated at the top and bottom of stopes.

While there has been a large number of methods devised to meet different conditions of occurrence of ore and methods of mining, yet in this connection only those methods are discussed that illustrate successful pillar-drawing under normal conditions and adapted to narrow and moderately wide veins and to filling and caving methods.

The usual operation of mining arch-pillars in narrow

FIG. 2. PILLAR-DRAWING BY CAVING, BRADEN COPPER MINE

A method of removing arch-pillars that has been employed with considerable success in the Australian mines may be used to illustrate such work as applied to moderately narrow veins. A stope having been worked out and filled with waste to within 10 or 15 ft. of the level above, the work of removing the remaining ore or the arch-pillar is begun. Winzes are sunk through the pillar from the level and a drift is run on top of the waste uncovering the waste-chutes previously used in drawing off ore from the stope. The drift is next enlarged laterally until the walls of the vein are reached and such supports as are needed are placed. Sections of the pillars ranging in length from 25 to 50 ft. and extending from hanging to foot-wall are thus blocked out. Beginning at one end of a section or block of ore, it is removed by retreating, but care must be taken not to undermine the sets in the level above. This is accomplished by placing two large timbers or draw-bars under the caps of the sets and supporting them with posts that stand on unmined ore at either end, or after the work has got well under way, one post will be placed on ore, the other on the waste-filling. See Fig. 1.

The sills of the undermined sets are held in place by chains until supplementary sills and braces in the nature of stulls can be placed. Filling is then stowed in the excavated space and held in place by stulls and lagging giving final and complete support to the sets. Successive sections are thus mined, the supporting draw-bars advanced and sills caught-up, and filling introduced; the advance being rapid, sure, and safe. Failure to properly catch-up the sills may result in a collapse of the sets and a consequent run of waste-filling from the stope above. The level would then be permanently closed and considerable ore lost by crushing of the arch-pillar; there would also be danger of a cave starting, which might seriously disturb the workings.

The problem of pillar-drawing in the Braden copper mine, in Chile, has been successfully solved by the adoption of a novel method, which is, however, little more than the caving system adapted to the mining of pillars.¹ The stopes in the Fortuna orebody of the Braden mines have lengths of 131 to 361 ft. and widths of 20 to 33 ft., while the intermediate pillars are 26 to 40 ft. wide. The vertical height of stopes is about 300 ft. The stopes stand full of broken ore until such time as the 'reserve' can be safely drawn upon. See Fig. 2. It has been calculated that two-thirds of the output of the mine must ultimately come from the drawing of pillars, and consequently the method adopted must meet the requirements of regular production and low cost, and at the same time not endanger the mine through collapse of the workings either in pillars or stopes.

Experience seemed to indicate the desirability of depending upon hanging-wall pressure to break up the ore and cause it to move to its point of delivery after the preparatory work has been done by means of large blasts

or a series of blasts. Dilution of pillar-ore through mixing with broken cap-rock, were the pillars to be left standing until the ore in the stopes is first drawn, was the deciding factor in the choice of method of drawing pillars finally adopted.

The stopes are extended to the desired height and left full of broken ore; the intermediate pillars are then attacked. The first operation is the opening of stopes on both hanging and foot-wall sides of the pillars, which are carried to the top of the finished stopes or at least one-half their height. The stopes are worked from the upper of two drifts run through the centre of the base of a pillar, connection between the drifts being made by vertical chutes, which are made funnel-shaped at the top. Space is provided in the pillar-stoppe for the miners by drawing off the surplus ore through the chutes. On the completion of the pillar-stoppe the pillar is almost entirely surrounded laterally by broken ore, and the unmined block of ore stands upon a base of limited extent, which is also perforated by drifts and chutes.

Beginning at the top of each chute, wide cross-cuts are driven across the pillar, the object being to determine the width of the pillar. The pillar is then honey-combed by broken-sloped chutes, which zigzag back and forth across the pillar from hanging to foot-wall. Further, small cross-cuts are driven across the pillar from stope to stope, thus giving access to a large part of the block of ore. The ore from the preliminary work of raising and cross-cutting is handled through the same passages that serve as manways. Sub-levels are also driven at more or less regular intervals throughout the height of the pillar, the first being spaced at a distance of about 16 ft. above the second of the two bottom drifts, and serves as a basis for the work of caving the pillar.

The preliminary work of driving, raising, and cross-cutting having been completed, the bottom of the first sub-level is attacked at regular spaced intervals and shallow pits are sunk. In the walls of the pits, as well as the sides and tops of the first sub-level and the lower raises and cross-cuts, numerous holes are drilled and charged with dynamite, which when fired shatters the base of the pillar causing it to settle and thus start the caving of the whole block of ore. The pressure of the hanging wall and the broken ore in the stopes acting together cause the pillar to disintegrate, and when the ore is drawn off through the chutes below, that in the pillar and the stopes mingle and move downward together and comparatively free of waste. Care must be taken in driving the cross-cuts and other passages that might come in contact with the broken ore in the stopes, otherwise danger to the miners is almost sure to result from running ground. Further, in order to ensure against mixing of ore, it has been found necessary to draw off the ore regularly and uniformly, and by so doing the subsidence of the cap and the holding back of the waste is handled to the best advantage.

An interesting method of drawing pillars is now in common use in the iron mines of our northern States

¹'Pillar Caving at the Braden Mines,' by J. D. Tallant, 'Teniente Topics,' June 1916, No. 6.

and in Canada. This is a combination of sub-level mining, pillar-drawing, and caving.

The lode at the Magpie mine, Michipicotan, Canada,² varies from 25 to 62 ft. in width, which variation is shown in Fig. 3. The method of development and working is given in both section and plan, Fig. 3 and 4. In the lower left-hand part of the plan the general method of procedure in opening up the block of ore to be stoped is shown; in the lower right-hand portion of the plan, the development work has been completed and stoping begun; while in the upper portions of the plan the stores are in various stages of exhaustion.

In the working-stopes the blocks of ore are subdivided into horizontal layers by sub-levels, which presents points of attack in the breaking of ore; the working face of each sub-level is carried in advance of the one directly

²'Block-Caving and Substopping,' by F. C. Roberts, 'Mines & Minerals,' June 1912, p. 674. 'Mining Methods at the Magpie Iron Mine, Canada,' by A. Hasselbring, Canadian Mining Institute, Bulletin, March 1917, p. 261.

FIG. 4. PLAN OF STOPES IN MAGPIE MINE

above, thus giving a bracketed effect to the stope-faces. The blocks of ore are then mined first by advancing with the sub-levels, following which the pillars are mined by retreating, but each working-face is protected by the projecting back of ore above. The ends of the pillars are drilled and blasted by holes placed vertically in both the roofs and floors of the sub-levels, the broken ore falling freely to the floor-pillars below, in which block-holes and funnel-shaped chutes are provided for the prompt and efficient handling of the ore. The miners are also able to retreat into the sub-levels should there be indications of serious falls.

As the work of mining the pillars proceeds, it is obvious that in the course of time the floor-pillars of the upper levels will lose their support through the removal of the arch-pillars and consequent abandonment of the levels below, and furthermore they become weakened by the constant fall of ore from the elevated stope-faces, which with the weight of broken ore will cause them to crush and collapse, ultimately falling to the bottom of the next lower stope-floor.

FIG. 3. PILLAR-DRAWING AT MAGPIE MINE

FIG. 5. DRAWING PILLARS UNDER FILLED STOPES

The first operation in pillar-drawing in this method is accomplished by overhand and underhand stoping, gravity giving assistance in breaking down the ore. The second operation consists in mining the floor-pillar by caving. Both are done at slight expense and with a high degree of safety and efficiency.

The drawing of pillars in massive deposits, particularly where the conditions of the ore and wall-rock are poor and bad, presents difficulties not ordinarily encountered, yet even under the most adverse conditions a large proportion of extraction from the pillars is possible. A good illustration of such work is to be found in the iron mines of the North as in Michigan and Minnesota.³ The work of mining is accomplished by overhand stoping and filling with waste commonly known as back-filling. See Fig. 5. On carrying a stope to a height that has been found by experience to be safe, the unmined portion of ore left standing or the arch-pillar is attacked next to one wall, preferably the foot-wall, and a break-through formed, whereupon the waste in the stope above runs into the lower stope until checked by filling the available space. By proper care in placing the breaking-down shots the back of ore is caused to cave and fall, being pushed forward along the stope by the downward movement of the incoming waste. Ordinarily the arch-pillar may be reduced to a thickness of 10 to 12 ft. or less by the usual work of overhand stoping, so that the work of breaking down the pillar is comparatively easy and when once begun may continue with little or no further effort except the removal of the broken ore, which gives room for the introduction of more waste from above. While there are possibilities of danger from the extensive crushing of the pillars and the loss of ore, yet with the exercise of proper care a large part of the ore can be removed with comparative safety to the miners and mine.

Necessity for the conservation of the ore supply even in the low-grade deposits has been responsible for the careful consideration of means to that end and the methods cited are typical of the work that is being done to bring about such results.

Quicksilver in 1917

The domestic output of quicksilver in 1917, according to statistics compiled by H. D. McCaskey, of the U. S. Geological Survey, was 36,351 flasks of 75 lb. each, valued at the average quoted market price at San Francisco (\$106.12 per flask) at about \$3,857,000. The output was the greatest since 1883. The production in 1916 was 29,932 flasks. The productive States were California, Texas, Nevada, Oregon, and Arizona. The output of California in 1917 was 24,251 flasks, against 21,045 flasks in 1916. Quicksilver prospecting and mining, stimulated by war-demands, have been active. In 1917 the Abbott mine became a producer, with prospects

of a considerable increase in 1918. The Helen mine continued production, and the Sulphur Bank made gains that are likely to be continued in 1918. The Big Injun was a new producer. The Patriquin continued production, and the output of the Bella Union and La Joya showed considerable gain. The New Idria yielded slightly more than in 1916 and remained the largest producer in America. The Cambria was idle but the Oceanic increased its output. The New Almaden and New Guadalupe both showed material gains. The St. Johns again made a large output. The Culver Baer, Great Eastern, Cloverdale, and Socrates all made gains, those of the first three being notably large.

The output of Texas was 10,759 flasks against 6306 flasks in 1916, and the increased production is credited to the Chisos, Big Bend, Mariposa, and Chisohm, in the order named. Further increase may be expected from the Terlingua district, which was long ago put on the map by these mines.

The production of Nevada decreased from 2198 flasks in 1916 to 916 flasks in 1917, the decrease having been due in part to loss of the Goldbanks plant by fire and in part to decreased production from the Lone district. Properties near Mina made notable increases, especially the Red Devils or Farnham and Drew properties. In Arizona and Oregon combined the production was 422 flasks in 1917 against 383 flasks from these States and Washington combined in 1916.

The market prices of quicksilver quoted in San Francisco increased from an average of \$81 per flask in January to \$126.25 in February, but declined to \$113.75 in March, \$114.50 in April, \$104 in May, and \$85 in June. In July the average rose to \$102 and in August to \$115, falling in September to \$112 and in October to \$102, rising again in November to \$102.50 and in December to \$115. The average for the year was \$106.12, but producers received, as usual, considerably less for metal sold at the mines. The high prices were due to greatly increased war-demands, principally for making fulminate for explosives, antifouling paint for ship bottoms, drugs, and storage batteries, and for amalgamating gold and silver ores, but were due also to the large increase of exports over imports. The exports of quicksilver for the first ten months of 1917 were 10,222 flasks, against 8880 flasks for the entire year 1916, and the imports were 4491 flasks for the first 9 months of 1917, against 5659 flasks for all of 1916.

Most of the output continues to come from properties that were producing before the War, but part of it comes from old surface material, for new development work and furnace construction require time and money, and quicksilver deposits, unlike the larger deposits of the more common metals, are not readily measurable in a quantitative way. Uncertainty as to war-demands and post-war markets and prices have prevented extensive financing of an industry in which there had been little profit for decades before the War. Some improvement in the treatment of low-grade ores is indicated.

³'Iron Mining in Minnesota,' by C. E. van Barneveld, Fig. 126.

Minerals Separation v. Butte & Superior

PART OF BRIEF FOR PLAINTIFF-APPELLEE

. Appellant's contention of non-infringement includes (and stands or falls with) the proposition of law that the patent in suit, as interpreted by the Supreme Court decision, covers and includes *every oil or oily liquid that has a preferential affinity for metalliferous matter over gangue*.

That this *must be* Appellant's contention is evident from the fact that Appellant's procedure since January 7, 1917, involves every ingredient, step, operation and result, that its earlier (and admittedly infringing) procedure involved (including the use of a small fraction of 1% of an oily liquid—pine oil—that does the work of the process), and in addition it involves the use of a large fraction of 1% of an oily liquid—petroleum—that does not, and cannot, do the work of the process, the two fractions when added together equalling 1% on the ore or more.

That this *is* Appellant's contention appears on page 44 of its brief:

"Hence we see that any oily liquid having a *preferential affinity for metalliferous matter over gangue* is included within the term 'oily liquid' in the claim. Since there is no question but that petroleum has such *preferential affinity*, and the court below has in terms so found, there can be no question but that they are included within the term 'oily liquid' contained in the claims." (Italics theirs.)

This construction of the patent is arrived at by mistaken emphasis upon an incidental thing and an entire failure to recognize the essential thing.

It is conceded by both parties and found by the court below that all oils possess the characteristic of preferential affinity for metalliferous matter over gangue. Comparatively few oils, however, possess the characteristic of producing a mineral-carrying froth. The soul of the invention of the process in suit resides in using an oil having the characteristic of producing a mineral-carrying froth; incidentally such oil will exhibit the characteristic common to all oils, of preferential affinity for metalliferous matter over gangue.

To construe the patent as if the only thing sought for in the oil is its preferential affinity for metalliferous matter over gangue is to specify a characteristic which is common to all oils and therefore does not serve to distinguish the oil required; and it overlooks that which does distinguish the oil required and specifies its essential characteristic, namely, its capacity to produce a mineral-carrying froth.

One has but to read the claims and the specification to demonstrate this, viz.

(Claims 1, 2, and 3):

"agitating the mixture until the oil-coated mineral matter forms into a froth,"

(Claims 5, 6, and 7):

"agitating the mixture until the oleic acid has been brought into efficient contact with the mineral AND has formed a froth therewith."

(Claim 12):

"agitating the mixture to cause the oil-coated mineral to form a froth,"

(Claims 9, 10, and 11):

"agitating the mixture to form a froth" [limited by disclaimer to the same mineral-carrying froth as the other claims].

It will thus be seen that the explicit requirement of every claim is that the oil or oily liquid in addition to coating the mineral particles must do the fundamentally essential thing, i. e., it must cause the oil-coated mineral particles to form into a froth.

This it does by reason of its mineral-froth-forming capacity or characteristic.

If the oil fails in this respect the process does not proceed.

If it is incapable of fulfilling this office—if it is lacking in this characteristic or power—it is not the oil or oily liquid of the claims.

The specification is equally explicit.

It sets out the discovery, the mode of operation, and the result, all as centering in the froth or scum thus constituted by the air-bubbles and their adhering oil-coated mineral particles.

And the Supreme Court decision, in upholding the patent as valid and to that end defining the process and pointing out its novelty over the prior art, specifies even more emphatically the operation of mineral-froth-formation, including the formation of a multitude of air cells, the adherence of the oil-coated mineral particles to them, the lifting of the latter by the former, and their accumulation as a floating froth, and specifies this froth as the result obtained by the process and describes it as consisting of air-bubbles modified by only a trace of oil in their films and carrying in mechanical suspension in their films a very high percentage of the mineral content of the ore.

Oils may have different characteristics. For example, preferential affinity for metalliferous matter over gangue, lifting force in water, stickiness, and, in the case of the process in suit, the modifying action which results in persistent mineral-holding-froth formation. One characteristic may be utilized in one process and another in another process.

The characteristic or power of oil to form a persistent

mineral-carrying air-bubble froth was first disclosed by the patentees here, and is the distinctive feature of Appellees' process, and is the only explanation that has been made by anyone of the process as used by Appellant.

By the very necessity of the case the patent is limited to such an oil or oily liquid as will do that thing and excludes every oil and oily liquid that will not do that thing.

And the Supreme Court so confines the patent by explicit and authoritative interpretation.

This is in epitome the prescription of the patent:

Given ore, water, acid, heat, and agitation nothing results.

Given ore, water, acid, heat, oil, and agitation nothing may result or something may result. If the oil is an oil that, like kerosene or fuel-oil, does not have the characteristic that produces mineral-carrying froth, nothing will result. If it is an oil that, like oleic acid or pine-oil, does have that characteristic, an air-bubble froth will result in which the bubble-films are modified by the minute amount of oil in them and hold or carry a very high percentage of the metalliferous matter of the ore. If the ore or the oil are new and untried a simple preliminary test, says the patent, must be made to determine whether the oily substance is suitable under those conditions in the respect of yielding the proportion of froth or scum desired, namely: a froth or scum carrying a large proportion of the mineral present.

That this description and prescription are sufficient the Supreme Court has already held.

And this inclusion of every oil or oily liquid that will do this work and exclusion of every oil or oily liquid that will not do this work, is imported into all of the claims, as is manifest on the face of those claims as pointed out above and on the face of the disclaimer with respect to claims 9, 10, and 11.

Appellant's brief seeks to escape the fatal force of this situation by misrepresenting Appellees' position.

It asserts by assumption that Appellees' position is that this fuel-oil and kerosene in Appellant's process is wholly inactive, wholly inert, for any purpose, does not take "any active part in the process," is used "only as a diluent to increase the bulk of oil."

This misrepresents Appellees' position. Appellees' position is this: These oils do not possess the capacity to produce mineral-bearing froth and it is immaterial therefore on a question of infringement whether they are inactive or active, beneficial or detrimental, in other regards. Whatever action ensues from their use is incidental merely, and is negligible and immaterial on the question of infringement.

They may stabilize the froth, they may tend to prevent metal dropping out of the froth or perform some other incidental thing; but it is purely incidental. They do not cause the process to work, and therefore they are not the "oily liquid" of the patent.

If the terms of the claims are to be construed by the real substance of the invention—if a given ingredient is

to be tested by the real work that it does in the process, or by its capacity to do, or not to do, that work—if the claims in their use of the terms of the art are to be intelligently understood and applied from the standpoint of the end and purpose in view, the function and operation to be performed, the results to be obtained—then the oil or oily liquid of the claims is to be interpreted and construed as such an oil or oily liquid as will do the essential work of the process, as will function and operate in the way specified in the patent, and in the claims themselves, and as will obtain the results defined in the Supreme Court decision, and to which, as that decision holds, the patent must be confined.

When you have once so construed the claims, when you have once so determined, as you must, that no oil or oily liquid is the oil or oily liquid of the claims that does not, and cannot, function and operate, and produce the result, there set out, it only remains in any particular case to determine whether the oil or oily liquid in question does in fact so function or operate and bring about the result. On this question of fact in the case of the fuel-oil and kerosene used as Appellant uses them the findings of the court below are clear and specific and certain, and they were based upon what was practically the concurring testimony of both sides.

And when Appellant contends that an oil or an oily liquid that will not produce the results obtained by the process is nevertheless the oil or oily liquid of the claims because it has a preferential affinity for metalliferous matter, it flies in the face of the Supreme Court decision which holds that the patent "MUST BE CONFINED" to the obtaining of those results.

* * * * *

The claims of the patent in suit, so far as the use of oil or oily liquid is concerned, define clearly, distinctly, and imperatively what must be used, i. e., an oil that is capable of producing a mineral-froth under the conditions of its use—and for the purposes of the only question of infringement presented in this suit, we may deal with the patent just as if it were restricted in terms to a fraction of 1% of such an oil upon the ore.

To determine infringement, therefore, is a perfectly simple matter and requires only the consideration of a fact. The only fact (if the procedure of the patent is otherwise used) that needs to be considered is, how much mineral-froth-forming oil is being used to form the froth. When the investigation discloses that the quantity of mineral-froth-forming oil is a fraction of 1% on the ore and that the results specified by the patent and the decision are obtained, infringement exists even on the strictest and narrowest construction of the claims. The infringer, upon this state of facts, can no more successfully resist the charge of infringement by saying, "But I also used other oils making in the aggregate of all kinds of oil more than a fraction of 1% on the ore," than if he should say, "In addition to the fraction of 1% of mineral-froth-forming oil which I used, I also used some

acids or some solids or liquids of various kinds and with various names and functions."

It is impossible to add apples and pears and get an aggregate of apples.

It is utterly immaterial upon the issue of infringement in this case (even assuming the narrowest construction of the claims) what non-frothing oils or what other things are used, if the user employs the procedure of the patent in suit and in that procedure uses a fraction of 1% of mineral-froth-forming oil, and obtains the results specified in the decision.

The Appellant is in just this position, and the whole situation on the issue of infringement is luminously clear.

The Findings of Fact Made by the Court Below on the Issue of Infringement

The Court below, facing all the witnesses who testified on the facts, and personally viewing the many experiments and tests that were made in court during the progress of the trial, and viewing the two processes in the mill (Appellant's and Appellees') on the last day of the trial, the one at the Appellant's mill and the other at the Timber Butte mill (one of Appellees' licensees) found the following facts:

that

"The larger part of the oil used by the defendant and all in excess of a fraction of one per cent on the ore, if not inert is ineffective, wasted, and injurious to the process and results";

that the petroleum-oils which constituted a large part of the oils

"seemed generally ineffective by the evidence of both parties";

that these petroleum-oils

"are ineffective to operate the process and that is because they have not the quality that contributes to bubble-making. * * * With these ineffective oils agitation will not produce froth and so there is no flotation of the metallic particles"; that

"Defendant uses the patent process, uses plaintiffs' invention of ore concentration by air-bubble flotation, uses the same elements in the same combination in the same way with the same function to the same, but poorer results"; that

"The addition of the excess oil no more adds to or changes the process, no more avoids infringement than would the addition of milk or other useless substance not a part of the process";

and that the excess oil was added

"merely to avoid the patent."

The Evidence

These findings of fact by the court below were based upon credible testimony of reputable witnesses produced by both parties—practical experts in this art such as Mr. Greninger, Mr. Chapman, Mr. Higgins, and Mr. Wiggin for Appellees, who not only testified to their

observations and opinions, but some of them made practical demonstrations of the facts in court; also Mr. Engelmann of the Ray Consolidated Company, a practical expert in this art produced by Appellant, who testified to mill-tests,* and Professors Bancroft, Taggart, and Beach, scientists produced by Appellant, and Messrs. Wilding and Wilkinson, practical experts who interpreted for the Court Appellant's tabulated statement and monthly reports as to its procedures both before and after January 7, 1917.

Mr. Higgins for Appellees demonstrated by a test carried on in open court that a mixture of fuel-oil and kerosene (two of the three components of Appellant's mixture) in an amount aggregating 18 lb. to the ton (fairly typical of Appellant's mixture), when added to a mixture of ore, water, and acid, would not upon agitation produce a mineral-carrying froth or effectuate any ore concentration whatever, but that when to that mixture of ore, water, acid, and 18 lb. of fuel-oil and kerosene, 4 lb. of pine-oil per ton of ore was added and the same identical agitation repeated, a copious mineral-carrying froth was produced, and ore concentration was effected. Mr. Higgins made a similar demonstration, trying first 2 lb. of kerosene with ore, water, and acid, which upon agitation gave nothing whatever in the way of a metal-carrying froth, and to which he then added 2 lb. of pine-oil per ton of ore and repeated agitation, whereupon a good mineral-carrying froth was produced.

Some of Appellant's witnesses testified to sporadic mill-operations said to be with petroleum alone, but they were discredited and the operations shown not to have been with petroleum alone. Janney admits knowing many oils that will not froth and another class that will froth and make the bubbles stable. Professor Bancroft, one of Appellant's scientific witnesses, repeatedly says that kerosene is not a frothing-oil and selects it as the typical non-frothing oil, and says of Appellant's mixture that it contains (1) the non-frothing viscous oil, fuel-oil (2) kerosene, which he had selected as the typical non-frothing oil, and (3) pine-oil which is a frothing-oil.

Appellant's brief apparently seeks to suggest, by italicizing the words 'kerosene' and 'alone' in the phrase "kerosene acid sludge alone" that the Anaconda company as Appellees' licensee sometimes uses kerosene alone in its great flotation operations. Kerosene acid sludge is not kerosene at all, but a by-product of the refining of kerosene, and it contains no kerosene. Mr. Wiggin says also (and this may help explain where some of the large amount of inert and useless petroleum-oil goes to in Appellant's process) that the Anaconda company has found that aluminous clay material in the copper slime probably absorbs some of the oil used, rendering that much of the oil useless for flotation, this explaining why it is found necessary to use more oil with the copper slime. Appellees' witnesses speak of the great excess of clay-

*"We tried at different times to run on straight fuel-oil, but we could never maintain metallurgical results."

gangue slime in Appellant's ore and of the probably large absorption of fuel-oil and kerosene thereby, and the reports of Appellant's mill superintendent show that of every 26.37 lb. of oil added in the demonstration mill run on April 29, 1917, more than 10 lb. were found running to waste in the tailing, where, of course, the proportion of gangue is large.

That the Appellant's procedure since January 7, 1917, is substantially the same process, proceeding by the same identical operation to the same identical result—the metal-carrying froth—is testified to positively by the practical experts Greninger, Chapman, and Higgins, produced by Appellees, and counsel for Defendant below stated that it had been satisfactorily proven by his witnesses that the same results are obtained with over 1% as with under 1% of oil and the operations of Defendant demonstrated this. He particularly referred to his witnesses, Professors Bancroft, Sadtler, Taggart, and Beach.

Appellant's brief cites no evidence or opinion to the contrary, and the Appellant in its brief here seeks the benefit of an argument to escape conviction of infringement by intimating or suggesting that it obtained by its operations a different result from that obtained by the process in suit. It cites no evidence to sustain this argument. It points out no difference whatever between the principle and mode of action and operation of the process as carried out after January 7, 1917, and as carried out for five years before that date, nor any difference whatever in the product of the process, the resulting froth-concentrate. The argument, therefore, not only lacks any basis in fact to support it but is in direct opposition to the testimony of the witnesses on both sides. The whole effort of the Defendant in the court below was directed at proving that the results obtained by large quantities of oil in the aggregate above 1% were identical with the results obtained by quantities below 1%, and its counsel urgently insisted there that the Defendant had established this fact.

However effective the argument now made might have been, if the facts of the case had supported it, it is utterly futile because the facts do not support it but on the contrary destroy it.

The case is well within the rule that was stated in the opinion in Butte & Superior Copper Co. against Clark-Montana Realty Co. and Elm Orlu Mining Co., filed at this term by this court.

"There are several assignments of error to the findings of fact, * * * The Appellant does not assert that the findings of fact are unsupported by competent evidence, he contends that they are contrary to the weight of the evidence. The trial court made its findings upon an evidently careful and painstaking investigation of the testimony and the exhibits, and after a personal inspection of the mining properties. We have examined the record sufficiently to see that the findings are all supported by the credible testimony of reputable witnesses. Upon settled principles which this court has always rec-

ognized, findings so made upon conflicting testimony are conclusive upon this appeal."

We have on the facts here a perfectly clear case of a user of the exact process of the patent in suit who seeks to escape the charge of infringement by adding thereto something other and different that does not go to the heart of the operation or change its substance or change the kind of product or result obtained. Under the law this does not relieve such user of the charge of infringement. There is no real dispute on the facts, and they are the sole determining test of infringement. The facts demonstrate infringement from January 7, 1917, to the time of trial.

The fuel-oil and the kerosene which, when employed in minute proportions in conjunction with minute proportions of a mineral-froth-forming oil and with a soluble frothing agent of the 1910 patent, sometimes benefit the result by preventing the dropping of some larger mineral particles out of the froth and by steadying and stabilizing the froth, may in the uselessly excessive quantities employed by Appellant effect that same benefit, or it may not. The weight of evidence is that it does not. But even if it does, that benefit does not change the process in its substance and does not change the results obtained in kind.

It is worse than foolish to say, as Appellant's brief says, that the result is different because the Appellant's profits are being reduced at the rate of \$1,000,000 per year, with the intimation that that was the sort of result the Supreme Court referred to in its decision. This is foolish because there was no ore concentration process known to the prior art by which any profit at all could be made except water concentration (and that did not involve oil) and the Elmore bulk-oil process (which required ton for ton of oil and ore and which even Defendant's witnesses all differentiate), and perhaps Cattermole (which recovered the metal and could only recover the metal by sinking it). The Supreme Court could not by any possibility have had any increase of commercial profits in mind as the "results obtained" to which it says the patent must be confined. And the argument is worse than foolish in that it discloses the emptiness of Appellant's armory of argument to support its contention of non-infringement.

It is also a simple begging of the whole question to say that the Appellant's froth-concentrate has contained more oil since January 7, 1917, than it did before, because the very question is whether the presence of the alien oil in the froth-concentrate that gets there from the operation makes that froth-concentrate any different in kind, or the operation by which it was produced any different in kind, and the evidence on both sides is that it does not.

It is idle too to argue that Appellant's froth has more oil in it since January 7, 1917, than before, and that that was the distinction the Supreme Court made between Appellees' froth and the prior art; for that was not the distinction the Supreme Court made. The Supreme

Court did not find in the prior art a froth the air-bubbles of which carried a large proportion of the metalliferous content of the ore and in addition a *large quantity of oil* from which it differentiated Appellees' froth merely by the *lesser quantity of oil* in it. That was emphatically not the situation. The Supreme Court found a broad novelty in Appellees' froth which it defined, as we elsewhere point out, and Appellant's froth since January 7, 1917, is as much that novel froth in kind as was Appellant's froth prior to that date.

* * * * *

Validity

The second question to be decided is:

"Has the Appellant proved the existence of any state of the prior art substantially different from that which was passed upon by the Supreme Court in the Hyde case?"

The answer is that it has not. The contrary answer (if a contrary answer be intended) is not urged in Appellant's brief with insistence or any indication of conviction.

The California Journal of Technology is the only document of the prior art that was not before the Supreme Court, but Appellant's brief does not even mention it. It appeared for the first time in the Miami case and was dismissed by Judge Bradford as discussing laboratory tests that far from suggesting the possibility of the invention pointed to an opposite conclusion. It was dismissed by the Circuit Court of Appeals in that case with a mere mention, and was dismissed by the court below in this case as detailing a "suggestive but rather misleading and abandoned experiment."

The new evidence mentioned in Appellant's brief at pages 63 to 71 does not relate to the prior art. The mill-operations there referred to with quantities of oil above 1% did not any one of them separately or altogether reproduce any process of the prior art. Those procedures only employed what Appellant's brief repeatedly terms "prior-art quantities of oil" (an ingeniously misleading expression) in subsequent-art procedures. As matter of fact every such mill-operation without exception included a soluble frothing-agent in the mixture employed, thereby utilizing an invention that was not made until 1909 or thereabouts, and every such operation employed a fierceness and violence of agitation that were undreamed of in the prior art, and every such operation employed a Janney machine, which gives a peculiar kind, as well as an extreme degree, of agitation, and which was not devised until 1913 or thereabouts. Similarly all of those operations employed as the main ingredient of the oil-mixture certain petroleum products that Dosenbach and Janney after two or three years of investigation (beginning in 1913 or 1914), during which thousands of oils and oil mixtures were tested, had discovered to be inactive in this process and yet not destructive of it. Such operations cannot possibly cast any light on the prior art.

The new evidence as to the enormously extending use and utility of the process since the testimony in the

Hyde case was taken, the new evidence as to the subsequent surprising discovery that a material which went completely into solution in the water and remained there and could not and did not coat the mineral particles yet caused a similar air selection and separation and lift and produced a similar mineral-carrying air-froth, and the new evidence of scientific men as to the philosophy of the process, all tend most strongly to confirm and emphasize the Supreme Court's conclusion of fact that a new operation and result was in fact obtained, and to confirm and emphasize the Supreme Court's discriminating definition of that operation and result as an air separation and lift and a modified air-bubble holding or carrying of the mineral matter in a froth that persisted long enough for convenient separation.

The argument made before the Supreme Court by counsel for Appellees here, and which is quoted on pages 64 to 68 of Appellant's brief, was an argument addressed in part to the use of a mineral-froth-forming oil of the patent in suit in proportions greater than 1% on the ore (in procedures which Appellees' counsel contended and their witnesses testified *did not represent the prior art*) and that argument is just as sound on the record in the case at bar as it was on the record in the Hyde case, for in this respect there is no testimony in the case at bar additional to that in the Hyde case. That testimony shows the failure that ensued when Mr. Higgins attempted to employ cotton-seed oil (a mineral-froth-forming oil of the patent) in an amount equal to 3.6% on the ore in a miniature plant, and the failure that ensued when Mr. Chapman put through the same operation in a full-sized plant with 1.8% of oleic acid. Appellant in its brief asserts that these operations were successful metallurgically and bases his whole argument upon that assertion. As the assertion is absolutely unjustified by the evidence, the argument based upon it utterly falls. Both operations were abject failures and entirely justified what was said of them in argument by counsel for plaintiffs in the Hyde case. The proper deduction from the results of these operations establishes the soundness of Appellees' position that, so far as the evidence showed in the Hyde case and shows here, the use of more than a fraction of 1% of an "oil of the patent" has not succeeded in the mill.

The evidence in the case at bar does not in the slightest degree disprove what these experiments established, for not a single one of the mill-operations testified to or proved in the case at bar with quantities of total oil at or above 1% on the ore, as we have already said, employed more than a fraction of 1% of mineral-froth-forming oil. The oils that were in fact employed in quantities greater than a fraction of 1% on the ore were alien oils that would not alone and of themselves and without the presence of a frothing-oil of the patent in suit or a soluble frothing-agent of the 1910 patent, in any proportion or quantity, large or small, effectuate the operation or bring about the result of the patent in suit. This new evidence therefore confirms the evidence on which the Supreme Court decision was based.

Placer Platinum

Platinum, osmium, iridium, palladium, ruthenium, and rhodium form a group of closely related metals, which are generally found as native metals more or less alloyed with each other. They are rarer than gold, and some of them, especially platinum, iridium, and palladium, are now more valuable and in greater demand than gold. Because of their difficult solubility, their fusibility only at very high temperatures, and their extreme hardness, they are especially suitable for use in the chemical and electrical industries. One of its most important present uses is in making sulphuric acid, for through catalytic action it brings about the combination of materials required to form that acid, which is needed for making fertilizers and explosives and is thus essential to sustain the feeding and fighting powers of our Nation.

Under normal conditions the United States requires about 165,000 oz. of the platinum metals per year. It produces only a few thousand ounces and is meeting increasing difficulties in importing sufficient quantities. In this emergency we find that we have not utilized all our natural resources and that we have lacked the imagination to foresee the value of some of these resources. Henry G. Hanks, a former State mineralogist of California, as far back as 1884 made the following statement: "If the miners could be persuaded to collect the platinum minerals an industry might be established of considerable importance. There is no reason why platinum should not be manufactured in San Francisco and the American demand in part or wholly supplied by this State."

A comprehensive survey of our platinum resources was begun by the U. S. Geological Survey during the field season of 1917, the work in California being done in co-operation with the California State Mining Bureau.

The problem of increasing the production of the platinum metals is closely involved in the production of placer gold. The modern dredge, which is capable of handling as much as 200,000 cu. yd. of gravel per month, has become a highly efficient tool, but it is capable of still further improvement. If the gravel is clean and comparatively free from sediment, the dredge recovers most of the gold and platinum from the gravel that is handled, but if a large amount of fine mud or sediment is mixed with the gravel, it is not so effective. Over 30 dredges were at work in 1916, in California and Oregon, and during that year 710 oz. of crude platinum was produced. By careful experiment one dredge operator estimated that his dredge has been losing $4\frac{1}{2}$ oz. of platinum per month. More efficient methods may yield some increase in the quantity of platinum recovered.

Old stream channels buried beneath the lava on the western slopes of the Sierra Nevada formed the feeders of the gravels in the areas along the foothills that are now being dredged. These buried channels are mined

by driving or tunneling under the lavas, bringing the gravels to the surface, and recovering the placer gold. Some of these old channels carry considerable platinum aside from the gold, and at a few places attempts are being made to mine them more extensively.

The hydraulic mines in northern California and southern Oregon are producing some platinum along with the gold. The proportion of the value of the platinum to that of the gold produced at some of these mines is about 1 to 20. Unmined gravel deposits along streams in this area contain platinum and should yield a considerable quantity of the platinum metals. The main problem at most of these deposits is to get sufficient water for mining. Large reserves of the platinum metals are probably locked up in these gravels, to be recovered when the cost of mining is reduced by more favorable conditions.

The beach sands along the coast of Oregon and California have long yielded gold and platinum. The sands mined include not only those of the present beaches, but of old beaches that now stand about 200 ft. higher. The sands of the present beaches were in places so rich that in the early days they caused one of the great stampedes recorded in the history of California. The problem of mining the black sands of the beaches has been an alluring one, and many attempts have been made to mine on a large scale. A successful method must be based on a thorough prospecting of the material, which varies in richness not only vertically, but horizontally.

No reliable method has yet been found to handle these beach sands, though during the season of 1917 preparations were being made at several places for working them on a large scale.

Some platinum is recovered by small sluicing operations that are in progress near the headwaters of many streams, where the gravels are shallow and where the gold and platinum are close to their source in the bed-rock. The platinum metals are generally supposed to be derived from the serpentine that occurs in many areas in northern California and southern Oregon. Wherever platinum seems to have been traced nearly to its source this rock is found. A roughness of the platinum and in some specimens a black or brownish coating, which is apparently iron oxide, indicates proximity to its source, but it has not yet been traced directly to the serpentine, although it is probably derived from this rock. Streams that drain areas of serpentine would seem to be particularly favorable for prospecting. At no place are the platinum metals concentrated in large quantities. Being rarer than gold, they are harder to find than gold. Iridium is in great demand, and the fact that it forms 10 to 40% of the platinum metals in nearly all the placer deposits in the United States is a special incentive to the search for more. The elimination of litigation and the equitable settlement of questions regarding surface rights and underground rights in drift mining and regarding the distribution of water for irrigation, power plants, and mining might also increase the output.

Potosi Mines, Santa Eulalia

*The mines of the Chihuahua Mining Co., and of its predecessor, the Potosi Mining Co., constitute part of the central group of the Santa Eulalia district, Chihuahua, Mexico. The important mines belonging to this company are the Santo Domingo, Potosi, Santa Rita, Fortuna, Coronel, Zubiate, and Leonidas. As their ores, the same as those of the great majority of this district, are present in the form of mantos and in caves, the latter being locally called *abras*, and as the mineralization frequently extends to the surface, it is logical that the early miners should have explored these deposits from adits, but even in times past, they were beginning to search for the deeper-seated orebodies. In 1888 development was undertaken by means of a central shaft, which penetrated to a depth of 150 metres, and which in that period was considered a notable work for Mexico. Another was sunk on the Santa Rita 370 metres deep, and another on the Coronel, 240 metres deep. The Potosi Mining Co. has developed its property by means of two shafts, one 550 and the other 370 metres in depth. All of these shafts are well made and well timbered. The mechanical equipment is on the highest plane of modern progress, and is manned entirely by Mexican mechanics. It also has a pumping plant established near Tabaloapam, which takes water from a well on the banks of the river Chuvisear. The water is pumped through a pipe-line 19 km. long, and is used for steam generation at the plant of the company, and also constitutes the supply for the workmen and for the town of Santa Eulalia. They have constructed, and have succeeded in maintaining, even through the recent years of trouble, a narrow-gauge railroad, which gives them an independent outlet to the old Robinson plant, where connection is made with the Central Railroad. The sampling of the ore is done at this point, where the cargo is broken. The Chihuahua Mining Co. from 1894 to 1896 operated a smelter at the Robinson Hacienda, in which were smelted, during that period, 28,555 tons of lead ore, from which was recovered 3768 tons of pig-lead and 529,450 oz. silver. The mines of this concern have been exploited at all times in the most active manner, and although it has always been necessary to do a great deal of development work, they maintained a minimum production of 300 tons daily in the earlier years of the enterprise, which has risen during the years of bonanza, until today the output reaches 800 tons per diem. Such a production gives one an idea of the large reserves of ore available, and it is interesting to note that the deposits are of remarkable uniformity, both vertically and horizontally, the diamond-drill having shown an uninterrupted persistence of pay-ore to a vertical depth of more than 800 metres, and extending over an area more than 70 metres in diameter without finding the limits of the deposit. The metallic content of the ore in the upper zone has been greater than that on the lower

levels although the diminution in value with depth has not been great. Neither has there been a complete change in character of the ore, the carbonate of lead predominating along with oxides of iron, although sulphides are becoming more abundant. As has been indicated, there exist, in all the levels of the mines, immense caverns, which possess irregular forms, and have at times surprising dimensions. For example, one cavern measured 200 metres long by 15 wide. In its upper part it was covered by a crust of carbonate of lead containing also nodules of galena. The iron was oxidized and the silver existed in the form of chlorides, bromides, and native metal. The floor of the majority of these caverns is formed of masses of ore fallen from the roof, although in some cases the floor is practically clean, while the walls are covered with crystals of calcite and gypsum. The ore in these caves is generally so soft that it is possible to bar it down, rarely requiring the use of dynamite. The cost of mining under these conditions falls below 12¢ per ton. Formerly it was the custom to begin the workings in the arch of the caverns, throwing down first the 'despegue,' that is, the crust of ore which covered it, by means of a system of scaffolding, but the cost of timber necessary for these structures was so great that they frequently omitted this precaution, trusting to the strength of the walls, with the result of detaching large slabs from the walls and precipitating the workmen to the bottom. It is said that thousands of men have lost their lives in this way.

In addition to the deposits in the form of mantos and in caverns, the mine of Santo Domingo also has a contact vein between the beds of limestone and a dacite dike, which traverses this property as well as the adjacent mines to the north and south. Also in the Potosi mine there exist deposits of zinc blende and calamine of such size that they have been able to mine 400 tons per diem of this kind of ore. These deposits are found in the upper levels chiefly, where they were first discovered, but they also extend to the lowest workings of the mine.

THE IRON ORE mined in the United States in 1917 amounted to about 75,324,000 gross tons, compared with 75,167,672 tons in 1916, an increase of 0.2% only. The shipments from the mines in 1917 are estimated at 75,649,000 tons, valued at \$236,178,000, compared with 77,870,553 tons, valued at \$181,902,277 in 1916. The general average value of the ore per ton at the mines for the whole United States was therefore \$3.12 in 1917, as compared with \$2.34 in 1916. The stocks of iron ore at the mines apparently decreased from 10,876,352 gross tons in 1916 to 10,560,000 tons in 1917.

GOLD consumed in the industrial arts of the country during 1916 was valued at \$51,061,187, according to the director of the U. S. Mint, of which \$41,120,149 was new material. As the United States production of gold during that period was \$92,590,300, the industrial consumption of fresh material amounted to 44% of the production.

*Abstract: Boletín Minero, Oct. 1917.

Concentrates

TIMBER-MEN in mines, to be safe from falls of ground, should do their special framing under timbered ground, not ahead of it.

JEWELRY demand in India is such that since the War started 20,000,000 sovereigns (\$4.80 each) have been melted to supply the gold needed in manufacture.

GOOD WIRE-ROPE LUBRICANT not only oils the wires, and thereby reduces the action of friction, but it also protects the rope from action of acids and other injurious elements.

WASTE ROCK, unless resting against strong barriers, is not an effective support for stopes dipping over 33 degrees; but below that it is quite effective. This is South African experience.

SILVER is mainly a by-product, and the greatest factor in its production is high prices for the base metals associated with it, rather than an increase in the price of the precious metal itself.

SILICA-GRAPHITE PAINT coated on the interior of steam-boiler drums prevents pitting and formation of scale. A little flake graphite added occasionally with the feed-water is also beneficial.

MIGRATORY NATURE of labor is illustrated by the fact that at the Hollinger gold mine, in 1917, there were taken on 2700 men and paid-off 2600 men. An average of 1045 were employed in all departments.

MANGANESE is a beneficial impurity in zinc ores treated by electrolytic methods. It oxidizes the iron, and is re-oxidized in the electrolytic cell. When re-oxidized it is again available to oxidize the iron, in fact, it acts as a catalytic agent.

HIGH COPPER CONTENT (0.86%) of medium-carbon (0.38%) steel renders the metal superior in strength, hardness, and shock resistance to that containing 0.03% copper. Behavior of copper-steel resembles that of nickel-steel.

CONCRETE made in cold weather should be heated during mixing. On subway work in New York, when the temperature is from zero to 20 or 30° above, a blast of distillate or gasoline is directed into the mixing machine. The subsequent 'mix' flows out warm, and sets slowly in the forms, not having a chance to freeze.

MOLYBDENITE occurs with copper at a depth of 620 ft. in the United Arizona company's mine, 32 miles south-east of Jerome, in the Copper Creek district. The mineral is found as kidneys, 4 to 18 inches thick, and assays from 2 to 30% MoS₂. A sample of this ore at this office

shows massive chalcopyrite with molybdenite on parting planes.

TRINITROTOLUOL is very stable and ignites only at high temperatures, and even then it does not explode. It does not freeze, as does nitro-glycerine, and has many advantages on the side of safety and convenience. When used alone it produces large quantities of carbon monoxide; but this can be entirely prevented by combination with other chemicals, such as ammonium nitrate, if these are added in proper proportion to produce complete combustion.

SIMPLE TEST for nitrate deposits, according to B. H. Bennetts of Tacoma, Washington, is to take about one gramme of the substance to be tried, put in test-tube or other container, add a little water, about as much lye (caustic soda) as will go on the end of a pocket-knife, boil, and smell. If no odor of ammonia is apparent, add a small piece of metallic aluminum and boil. If the material contains any nitrates the odor of ammonia will be evident in a few minutes.

PRECAUTIONS to take against misfired holes are: (1) careful handling and storage of fuse; (2) careful storage of detonators in a dry place and not to keep them too long in the mine; (3) care in capping the fuses to see that no sawdust remains in the cap; (4) fasten the primer cartridge to the fuse; and (5) in blasting in wet places grease the fuse, especially at the junction of the cap, tie the paper of the cartridge tightly to the fuse, and grease the connection.

SUB-ARTESIAN WATER, amounting to 1,000,000 gal. daily, is flowing in the Edna May gold mine, Western Australia. The veins and country rock are almost impervious to water. The water met with comes from fissures caused by intrusion of many granite dikes, is under considerable pressure—80 lb. at depth of 300 ft.—and is probably derived from rain on the granitic rocks that surround the district. In the Deep Levels mine adjoining, the cracks made by the dikes and carrying the water were sealed by the cement method.

MINING methods in New York City—in new subways—vary considerably. In the sand and gravel strata, close timbering is necessary, with half sets. In hard-pan—gravel and clayey matter—a shield is used, this being pushed ahead as excavation proceeds. In rock—a schistogneiss—ordinary drilling and blasting methods are in vogue. Mining in the city is of far greater extent than generally thought, and by the end of 1918 there will be 308 miles of subways. This does not involve excavating a small tunnel, but one the full width of a street and often wider. At the same time traffic on surface must not be interfered with by underground work. Eventually there will be 600 miles of underground lines, costing \$400,000,000 in all.

THE MINING SUMMARY

NEW YORK

Financial Situation.—Sale of Chilean Nitrate Deposits; a Review of the Industry.

In view of the unsettled international situation, and prophecies of disaster from a certain section of the press if Japan were to take a more active charge of Allied interests in the Orient, the general condition may be described as one of nervous indecision. Trading in stocks and securities has been reduced in volume and Japanese bonds, in particular, have sagged. Bank clearings show an increase of about 10% over the same week last year, and this may be taken as an indication that general business expansion is taking place. The ultimate topic of conversation in financial circles is the next Liberty Loan, what rate of interest it will bear, and date of maturity. New York is vitally interested, and realizes that the success of the next issue may again be decided by the support given here. It is now known that the City came forward at the last, when the rest of the country had practically ceased subscribing to the second issue, and made its total up to \$1,413,045,800, thus assuring the success of the loan. It is generally anticipated that the next issue will bear interest at 4½%; this would seem inevitable. Present market prices of the last issue indicate that buyers have already lost an equivalent to twelve months interest in depreciation. The comparatively ready sale of these bonds at par has demonstrated the patriotism of millions of subscribers, but subsequent issues must be placed at higher interest rates, and the question of increased cost to the country must be recognized. A loan that could be successfully floated at 3% would solve many a financial problem; and there is no question that this could be done with comparative ease by an issue of premium-drawing bonds. If the prejudices of the few against anything in the nature of a lottery could be subordinated to the fact that an immense saving to the country would result, the issue would soon be an accomplished fact. Consider the salient features: The loan would be subscribed with only a small proportion of the wastage of labor and money now needed to make such an issue a success. With an issue of \$5,000,000,000 in 30-year bonds the saving in interest, with the rate reduced from 4½ to 3%, would amount to \$75,000,000 per annum. If \$25,000,000 of this were spent in premiums, to be drawn annually or semi-annually, there would be a net saving of \$50,000,000 per year, or \$1,500,000,000 during the life of the loan, in addition to the saving on interest and principal on bonds which may draw premiums. This scheme has been ably championed by J. W. Harriman, president of the Harriman National Bank. The figures are incontestable, and the arguments unassailable. Critics are silent. The appeal to human nature, and the recognition of the fact that even the remotest prospect of a prize will invariably insure the success of any loaning operation, will ultimately be recognized as a factor in national financing, and the premium bond will then come to stay.

The Chargé D'Affaires for Chile advertises in New York papers the sale by auction, on August 10 next, of 9,906,402,-886 metric quintals of nitrate land in Chile. Fourteen lots will be offered to comprise this total, and the Government

places a minimum reserve price varying from 10 to 25 centavos per quintal, averaging 23 centavos. The metric quintal is taken to equal 100 kilogrammes. Payment is to be made in gold at a standard rate of exchange of 18 pence (36 cents) per peso. The figures of 'caliche' reserves in the various plots are stated with a precision that questions verisimilitude and invites suspicion, but intending buyers may rest assured that this is merely the result of arithmetical exactness in the multiplication of approximate estimates. Those who are aware of the methods adopted in estimating the nitrate content of such ground know that the resulting figures are only approximate. As a matter of fact such estimates are a good guide to the probable quantity of caliche available, but nothing more. As regards actual nitrate content, this may be roughly estimated by considering the minimum reserve price put on the particular lot, and may vary according to the proximity of the deposit with reference to existing or future railroads. Water supply is also a factor in the estimation of market value of caliche ground. To the uninitiated, the Chilean government's method of disposing of its properties may seem strange but, nevertheless, the scheme has its good points. Intending purchasers know precisely what they are buying. The deposits are all on the surface or near it, and can be sampled cheaply with comparative ease. Checks made on the calculated contents of a lot by independent engineers will usually show that the official figures under-estimate the amount of caliche available. Such figures do not include any allowance for possible or probable deposits that may be found at depth; but should such developments occur the new reserves would become the property of the owner. Such prospects are, however, remote. If successful, the sale in August will dispose of about a billion tons of caliche. This figure suggests that some more ambitious scheme for the treatment of this material might be considered. As a preliminary it may be said that among engineers the general impression is that the proposed plant to extract nitrogen from the air, which has been under consideration for so long, will not rival or interfere with the Chilean industry in any way. The cost of producing artificial nitrate will always be high. If cheap power is available it might well be used for purposes of manufacture of material that cannot be cheaply produced from natural deposits. The cost of Chilean nitrate may be lessened in spite of frequent assertions to the contrary. A recent contributor to the Mining and Scientific Press, in disagreeing with this view, cited the high fuel expense necessarily involved in treatment of caliche. A parallel assumption might well be made with reference to coal requirements for New York City, but recent investigations have shown that the abolition of all the small plants and establishment of a few central power and heating stations would result in the saving of several million tons of coal annually. The same argument applies to caliche treatment. To the visiting engineer nothing in the whole scheme of operations appears so absurd and illogical as the entire lack of any idea of centralization. 'Ofcnas' under the same control, and even within half of one another, operate independently in every way. There is an unnecessary multiplication of general expenses, a waste of fuel, and an absence of any co-

ordination in research work that is lamentable. If the billion tons of caliche land now for sale contained but a fraction of its value in metal of almost any kind, the question of a plant of adequate size would receive immediate consideration. Chile has not received the attention it deserves from big corporations interested in nitrate; and yet nothing is more certain than that there will always be a brisk demand for Chilean nitrate at a reasonable price. One plant built on common-sense lines and operated on an approximate tonnage of caliche, certainly not less than 5000 tons per day and preferably twice this amount, would demonstrate that the economical production of artificial nitrate is out of the question until the existing natural deposits have been worked out; and this will take many years. The technological problems involved in the treatment of caliche and production of high-grade nitrate are almost negligible, although variation in composition may involve minor modifications in method in different localities. Problems to be solved to ensure a satisfactory recovery are entirely of a mechanical nature, and are far from insuperable. Lack of co-ordinated research by practical engineers is mainly responsible for the lack of progress; and a hesitancy on the part of the more conservative owners to install modern equipment is excusable and may be attributed, in no small measure, to the dubious results obtained from the installation of an up-to-date equipment of questionable applicability in the nitrate industry. Progress has also been seriously hindered by the autocratic control of all filtration patents, through an apparently weak spot in Chilean patent law, for the purpose of suppressing competition. If metallurgical engineers, who have proved their ability in those industries where wet metallurgical practice has been revolutionized by new methods in the treatment and mechanical handling of slime, could co-operate with the chemical engineers of the Chilean 'pampa' the result would be satisfactory to all concerned. At present the rival camps are far apart. The chemists hold somewhat aloof and adopt a superior and mysterious attitude, which creates the impression that the publication of some new, certain, and infallible process is imminent. The metallurgists have failed in not treating the problem from the broad engineering standpoint, and by insisting that its solution lay only in the adoption of some patented machine rather than by a modification in method in conjunction with the use of modern appliances. The writer of these notes is conversant with the subject, having been recently in Chile.

CRIPPLE CREEK, COLORADO

Myron Stratton Home Corporation.—Leasing Activities.

Cripple Creek mining companies paid \$61,103 in dividends to the Myron Stratton Home Corporation during 1917, according to annual statement of the McMahon Audit Co. to the trustees. Portland company paid on 504,333 shares owned by the Corporation \$60,520. The stock is valued at \$756,499. Granite company paid \$430, and Isabella company \$153. Stratton Cripple Creek Mining & Development Co.'s report shows total receipts of \$32,585, of which \$26,598 was paid by lessees as royalties. Total assets of the Myron Stratton corporation are given at \$7,590,342, an increase over those of 1916 by \$188,605.

Four mining properties on eastern slope of Ironclad hill were loading ore by team on February 9 for consignment to the Golden Cycle mill at Colorado Springs. Shippers were Jerry Johnson, operated by Cripple Creek Deep Leasing Co.; Forest Queen, by Edwin Gaylord; Pride of Cripple Creek and W. P. H., operated by lessees.

United Gold Mines Co.'s leased properties in February yielded 2000 tons of ore worth \$40,000 gross. Producers were the Trail, Bull Hill, 1435 tons; W. P. H., Ironclad

hill, 315 tons; Montrose, Ironclad hill, 35 tons; Bonanza, Battle mountain, 105 tons; and Damon mine dump, Ironclad hill, 105 tons.

Lessees of the Elkton Mining & Milling Co.—four sets—produced 600 tons, averaging 1 oz. per ton, during February. Company is now driving on Raven vein from 1100-ft. level of the main shaft, through undeveloped territory to the north.

Index mine, on Gold hill, owned by Index Gold Mines Co. and under lease and bond to El Paso Extension company, will commence shipping during the coming week.

Komat Leasing Co. has resumed operations at Victor mine, Bull Cliffs, this district. Property is owned by Smith-Moffat Mines Co., whose management has modified terms in the new lease.

Teams have been busy every day this week on the clean-up shipment of Elmer Smith from the Howard shaft of the Mary McKinney mine on Gold hill. He recently sold the lease to the Victory Gold Mining Co., of which H. J. Newton, of Denver, is president.

Golden Cycle Mining & Reduction Co. paid dividend of 3c. per share, or \$45,000, on March 10. This is the third monthly distribution for present year.

Rose Nicol Gold Mining Co.'s shares have been in demand the past week, 51,000 selling on March 9 at 8½c. each. A year ago they were quoted at 4c. or under. Rose Nicol is under lease to Camp Bird Mining, Leasing & Power Co. Ore has been opened on the 800-ft. level, as well as in the Roosevelt tunnel at a depth of 2100 ft. in Rose Nicol ground. Rose Nicol adjoins Portland company's Battle Mountain estate.

PLATTEVILLE, WISCONSIN

Conditions Early in March.—Ore Ranges.—New Companies at Benton and Cuba.

Operating conditions in the zinc region were better during the first half of March, enabling an output of 9756 tons of mine ore and 4841 tons to smelters. Local refiners received larger quantities of raw ore for dressing to 60%. Lead ore in reserve is 2000 tons, and producers are selling 200 tons per week, apparently by agreement. Iron pyrite shipments have increased from 500 to 1000 tons weekly. Roads did not improve much, and a storm on March 10 put numbers of plants out of commission.

Two great zinc-ore ranges traverse this field, one running from Highland on the north to a point south of the Mineral Point Zinc Works, the other crosses this near Linden, going almost north and south to the Mississippi river south of Galena, Illinois. South of Platteville, the geographical centre of the field, there are no great districts until Benton is reached. Geologists have long contended that a big connecting range occurs in this long stretch of practically undeveloped ground, and many hold that a 'mother lode' will be found along LaFevre River valley east of Cuba. Others contend that the connection will be found south and west of Platteville. Some excellent deposits of zinc have been found east of Cuba, but within the past year several rich strikes have been made that rather confirm the theories of those partial to future development of the Cuba district. The Hercules Mining Co. is one lucky in this respect. Another is the Connecting Link Mining Co., also in this neighborhood; and the C. S. & H. Mining Co. is working profitably on considerable ore, although of low grade. The Baxter and Raisbeck mines here 10 years ago were rich producers, and farther west was the Board of Trade company. An adjoining lease known as the Little Dick was necessary to complete this company's holdings, but the management was unable to negotiate a deal, and when the line was reached the Board of Trade company

stopped work, and sold its big equipment. The range continues into the Little Dick land, which has also remained idle since that time, and attempts are being made to renew operations in this area.

Benton.—Frontier Mining Co. of Indianapolis, operating zinc-ore producers in this district, has been one of the most consistent dividend-paying companies in this field. The Calvert, Bearcat, Middle, Burr, Bull Moose, and Grotkin mines have a combined weekly output of 800 tons of 36 to 42% zinc concentrate. On Hirds No. 1 and 2 are extensive deposits of low-grade ore not being mined because of unfavorable markets. This company is developing a number of new producers in the Galena district. A report issued recently by James H. Billingsley, president of the Frontier company, shows that the labor situation is good, some attention has been given to road building, insuring open highways at all seasons of the year regardless of weather, and powder and steel have doubled in price, with hoisting cable impossible to obtain. On March 10 there was 1500 tons of zinc ore in bins at the various mines piled up on account of weather. Company employs 350 men, operates its own boarding-houses, and displays unusual solicitude for the welfare of its employees in reading and club-rooms. Sales of zinc ore are made under contract, mainly to Graselli Chemical Company.

Cuba City.—This district, better known for large shipments of high-grade refinery ore made for several years—output of National Separators & Zinc Concentrating Co. of New York—is becoming the centre of extensive developments that have great possibilities for production of mine ore. The last concern to start here is the Hercules Mining Co. of Wisconsin, with a capital of \$100,000. Officers are prominent men of Dubuque, Iowa. The president is H. H. Busch. The general manager is Harry Seemiller, and underground manager is Robert Fox. Leases obtained on the Duncan and Scott farms comprise 400 acres of valuable mineral lands two miles east of Cuba City. Other leases have been secured for later development. On the Scott farm several borings made recently are all satisfactory, showing rich zinc with much lead ore. A two-compartment shaft is down 60 ft. Ore will be raised by April 1. Power-plant has been provided and a 100-ton mill will be built.

DENVER, COLORADO

Possibilities of Developing Oil-Shale Deposits.

Oil-shale possibilities in this State are discussed by Victor A. Alderson in 'Rocky Mountain News' of March 10, although he mainly reviews work done on Scotch shales and report of David T. Day of U. S. Geological Survey on Colorado and Utah deposits. The following conclusions are deemed conservative by Mr. Alderson: (1) Production of crude oil alone from shale cannot now compete commercially with oil from flowing wells. However, the increased demand for oil, decreasing production, and steadily enhanced price on one hand will be met by an almost inexhaustible supply of oil-shale, cheap mining, improved method of distillation, and valuable by-products, which will undoubtedly, in the near future, make the oil-shale industry a strong competitor of the flowing well, and in the by no means distant future its successor. (2) Oil-shale industry is not in ordinary parlance a poor man's game. The technical and chemical problems are numerous, and require high scientific ability for their solution. (3) A plant of 500-ton daily capacity is as small as can be operated permanently and successfully, as profits will depend chiefly in large tonnage handled. In this respect oil-shale industry bears same relation to oil that Utah Copper and other great copper mines bear to copper mines in general. (4) An investment of \$150,000 is as small as can be safely counted

on to make a single project successful. (5) Labor is cheaper in Scotland than in the United States. The Scotch shale produces more ammonium sulphate than Colorado shale—all other elements that enter are distinctly in favor of Colorado shale. (6) Favorable features in oil-shale industry in Colorado are: (a) enormous extent of deposits; (b) great thickness both of medium and high-grade shale; (c) horizontal positions of strata and their height above the level of creeks, a combination, that affords cheap mining; (d) adequate water supply for condensing and cooling-systems of both distilling and refining plants; (e) accessibility and nearness to railroads and markets; (f) richness of the shale.

ROCHESTER, NEVADA

New Tungsten District.—Nevada Packard and Rochester Mines Companies.

Mill City.—This district is fast becoming a leading tungsten producer in the country. Over 100 tons of ore, containing from 1½ to 3% WO₃ is being shipped daily. Output is increasing rapidly. L. A. Friedman's claims are the principal producers, shipping 75 tons daily. A compressor

MAP SHOWING SITUATION OF MILL CITY, NEVADA,
THE NEW TUNGSTEN DISTRICT

was installed last month. The Sutton group, which was the first producer, is also putting in a compressor. It is stated that the option recently taken on the Copley, Gavin, and McFarlane claims, involving \$75,000, was for W. J. Loring of San Francisco. Mines are only a short distance from Mill City station on Southern Pacific railroad. Ore is sent to a concentrating plant at Toulon. Treatment and shipping costs are about \$18 per ton.

Packard.—Nevada Packard Mines Co. is treating 100 tons of \$8 ore daily. Mill additions are complete and an extraction of over 91% is being made. Two-compartment winze has been started from the mill adit-level.

Rochester.—Rochester Mines Co. is treating 190 tons daily, yielding \$65,000 monthly.

Lower Rochester.—Buck and Charley company is making regular shipments of silver-gold ore to Kennett smelter, California. Occasional lots are sent from the Octopus and Flunkey claims to same smelter.

REVIEW OF MINING

ALASKA

Juneau.—Alaska Gold Mines in February produced 140,305 tons of ore assaying 93.4c. per ton. Extraction was 79.76%. January results were 179,300 tons of 90.3c. ore, and 77.85% recovery.

Kennebecott.—Kennebecott Copper Corporation produced 5,888,000 lb. during February. A year ago yield was 7,990,000 lb., and two years ago 9,750,000 pounds.

ARIZONA

Ajo.—New Cornelia in February produced 3,606,000 lb. copper, of which 2,522,000 lb. was in electrolytic cathodes, 538,000 lb. in cement metal, and 546,000 lb. in smelting ore.

Bisbee.—Shattuck-Arizona in February produced 854,042 lb. copper, 66,765 lb. lead, 6590 oz. silver, and 73 oz. gold.

Calumet & Arizona in February yielded 2,900,000 lb. copper, against 4,748,000 in January.

Calumet & Arizona company's central three-compartment shaft has been sunk to 600-ft. level, from which total openings amount to 2500 ft. In No. 1 cross-cut low-grade ore has been cut. Water-courses have been opened recently and will be followed.

Recently opened good ore on 1450-ft. level of the Denn-Arizona is said to be improving. Reports of a merger of this and Shattuck company are denied.

Boreas property has been shipping regularly, and developments of the last week have been encouraging to lessees.

Chloride.—Hackberry Consolidated's shaft is down 700 ft. on incline, to be sunk to 1000 ft. Vein is being followed. Company contemplates erecting a mill to treat its lead-zinc ore.

Clifton.—Shannon Copper Co. produced 788,000 lb. metal in February, against 792,000 lb. in January.

Constellation.—Arizona Copper Belt Mining Co., operating in Black Rock district of Yavapai county, is opening ground at 300 ft. depth. Some good copper-silver-gold ore has been exposed. W. J. Diltney is president.

Globe.—Gibson Consolidated Copper Co.'s new mill is being designed by H. K. Burch. Ore shipments are over 200 tons per month. F. F. Towle is manager.

Jerome.—Mineralization is much heavier in drift No. 14 on 700-ft. level of Verde Combination, considerable pyrite appearing in the schist-porphry contact. A winze has just been started from bottom of No. 13.

Pittsburgh-Jerome announces that encouraging showing of chalcopryrite in quartz, some 90 ft. long, has been opened on 900-ft. level.

Shea Copper Co. has opened silver ore containing 40 oz. per ton on the 360-ft. level.

Mayer.—R. C. Houston has opened rich silver ore on Pine creek in the Turkey Creek district. So far \$2000 has been extracted.

C. Peck silver mine, in Mayer district, has been acquired

by W. W. Williams of El Paso. Dump contains 200,000 tons of high-grade ore. This is to be treated and mine reopened.

Metcalf.—Arizona Copper Co. produced 3,600,000 lb. in February, against 2,500,000 lb. in January. Operations have not reached normal capacity since the strike. In February 1916 output was 4,600,000 pounds.

Miami.—Porphyry Copper Co. has cut a station at 500 ft. depth and is cross-cutting, while at 600 ft. a station is being cut, preparatory to driving south to Live Oak ground.

At a cost of \$40,000 Inspiration Consolidated is installing an automatic block system throughout its mines. Every entrance to ore-haulage drifts will be protected by semaphores and lights, as well as every short section of the main track. The change is expected to speed up ore movement, as well as improve safety conditions.

Oatman.—Cross-cutting from 500-ft. level of Aztec in search of faulted vein of Tom Reed, has, it is reported, cut a new orebody 87 ft. wide, averaging \$25 per ton.

Fifty-one feet of \$15 ore is said to have been opened in eastern part of the Gold Road mine.

Cross-cut on 965-ft. level of the United Eastern is now in ore 20 ft., being similar to that on 665-ft. level. Company pays 50c. per share on March 26, equal to \$68,150.

Gold Ore reports that cross-cut on 650-ft. level has opened 10 ft. of \$25 ore.

Prescott.—Shannon Copper Co. paid \$125,000 for Yeager Canyon mine, it is announced. Engineers state that the mine is opening well and has good possibilities. While under option \$75,000 was spent in development and sufficient ore is opened to pay purchase price. Depth is 1100 feet.

Tucson.—Extension of El Paso & Southwestern railroad from Tucson to Mesa and Clarkdale, behind which is D. C. Jackling and others, is reported as likely to be started soon.

Wenden.—Activities in Bill Williams, Cunningham Pass, Sunset, and Wenden districts of Yuma county include early installation of machinery at Cactus Queen; commencement of work on manganese deposits a few miles up Bill Williams river from Cactus Queen; opening 2 ft. of rich copper-gold ore by Black Giant Mines Co., shaft-sinking, and recent erection of compressor and engine; lessees near Black Giant property are shipping regularly; and resumption of work at the Wenden copper mine. Cunningham Pass district is said to be suitable for lessees.

CALIFORNIA

Amador City.—Bunker Hill shaft is to be sunk several hundred feet deeper, in hope of developing better-grade ore. Assessment of 10c. per share has been levied to finance the work.

Arbun.—Large deposit of chrome has been discovered on ranch of Ivan H. Parker, 8 miles from here. A company is being formed to develop it.

Baxter.—Mohave United M. & M. Co., operating in San

Bernardino county near the Nevada border, reports that Eastern people have agreed to finance it. Several hundred feet of preliminary work has been done, also churn-drilling to 300 ft. Average assays of ore opened are 7% copper and fair gold and silver contents. Machinery is to be ordered at an early date. P. H. Lietzow is manager.

Bishop.—Cooper Shapley and associates of Bishop are arranging for building a concentrator at tungsten mines near Round Valley, 12 miles from Bishop. A large deposit of medium-grade ore has been developed. Some difficulty is experienced in securing equipment.

Copper City.—Shasta Belmont company is completing arrangements for early ore shipments. Road will be improved from mine to Heroult, and additional equipment installed. Ore assaying 7% copper has been opened in lower adit.

Etna Mills.—Stamp-mill at Blue Jeans mine is nearly complete. Considerable ore is said to be ready for treatment.

Forest.—A 400-ft. drainage-adit has been completed at North Fork mine. Driving proceeds steadily on fair-grade quartz. George F. Stone, the manager, is looking for a vein believed to occur deeper. Development of ore-shoot lately found near shaft will soon be started.

Happy Camp.—Platinum production of placer companies operating on Klamath and Salmon rivers is reported to be increasing.

Klamath River Dredging Co., working at Walkers bar since 1915, has acquired additional ground adjoining.

Orleans Bar.—Placer operations in this Siskiyou county district will be reduced this season owing to light snowfall in mountains. Marcussen, Reynolds Creek, and Bonaly properties are hydraulicking.

Oroville.—Western Ore Co., operating chrome claims at Lime Saddle, near here, is to erect a concentrating plant at an early date.

Redding.—Bully Hill copper mines and the 15-mile Sacramento Valley & Eastern R. R. are reported to have been sold. Property has been leased to Walter Arnstein from General Electric Co. Ore is shipped regularly to the smelter at Kennett.

Trinity Center.—Estabrook Gold Dredging Co. has erected a saw-mill on Rancheria creek to cut 1,500,000 ft. of timber for its No. 2 dredge. This boat will have a hull 70 by 155 ft. Buckets are to be of 20 cu. ft. capacity. Machinery will weigh 1500 tons.

Weaverville.—Lagrange company has plenty of water for hydraulicking, keeping three giants busy day and night. Returns from this property in recent years are as follows:

Year	Gold, etc.	Opera- tions	Interest, etc.	Dividends	Less
1916	... \$41,148	\$76,097	\$21,361	\$56,310
1915	... 55,062	81,879	24,978	51,795
1914	... 83,627	108,435	18,764	43,572
1913	... 122,957	100,882	12,207	\$67,500	57,632
1912	... 151,443	96,556	17,845	52,500	15,458

COLORADO

Canyon City.—Zinc-oxide plant has recently been erected here under supervision of A. B. Augustine, who constructed a similar one at Leadville.

Central City.—Mines on Quartz hill may be drained and re-opened if local capital is procurable. The Miners' Association is considering the project.

Cripple Creek.—Cresson Consolidated reports a profit of \$48,702 for January. Cash on hand, plus 25 cars of ore in

transit, amounts to \$1,067,357. Usual monthly dividend of 10c. was paid. Ore-reserves on February 1 were valued at \$3,271,962. Ore shipped was rather poor in January. New orebody on No. 10 level is good, grab-samples assaying \$40 per ton. Diamond-drilling in No. 8 shows 88 ft. of \$23 ore.

Isabella Mines Co. reports 15 sets of lessees mining on Bull hill. Of these leases, nine are operated on the split-check system, one on royalty basis, and five on dumps. All lessees are doing well.

Georgetown.—Urad mine in Dally district is producing molybdenite. Forty men are employed in mine. Aerial tram 2400 ft. long carries ore to 200-ton mill. Dressing consists of ball-milling and flotation apparatus.

Leadville.—Western Zinc Oxide Co.'s plant has been operating at full capacity, 50 tons daily, for several months. There is good demand for its product by paint and rubber manufacturers. Carbonate ore is treated in the plant. J. B. McDonald is manager.

May Queen Leasing Co has blocked out a good deal of 24% zinc carbonate ore, shipping 25 tons daily to the Western Zinc Oxide plant.

Pingrey Mines Co. is busy opening its molybdenite deposit at Climax, in charge of O. A. King. Ore averages 1% MoS₂.

IDAHO

Adair.—Richmond M. & R. Co. reports for 1917 that shipments totaled 7766 tons of ore, assaying 6.17% copper, and 0.156 oz. gold per ton. Receipts were \$292,117, less \$110,650 for freight and smelting. Labor and supplies cost \$84,231, leaving profit of \$97,235. Dividends amounted to \$84,000. On 150 and 280-ft. levels ore carries 6% copper. B. N. Sharp is manager.

Elk City.—Rich gold-silver-copper-lead ore has been opened at depth of 100 ft. in Billie Boise mine, 14 miles south of Buffalo Hump, in central Idaho. Mine is under lease to George Bancroft of Denver, Colorado.

Hailey.—Federal Mining & Smelting Co.'s North Star mill is being overhauled. In its Independence mill, a mile from the North Star, considerable 8% lead and 20-oz. silver ore has been developed.

Kellogg.—Pine Creek railroad construction is to be resumed by the O.-W. R. & N. Co. Suspension was due to difference between contractors and railroad company.

Mullan.—Federal Mining & Smelting Co. is treating 1000 tons of ore daily at its Morning mill. Mace No. 6 adit will be started again in April or May, and may be extended 1700 ft., giving a depth of 1200 to 1500 feet.

Consolidated Interstate-Callahan Mining Co. in last quarter of 1917 shipped 2299 tons of crude zinc ore and treated 31,115 tons locally. Total metal contents were 11,968,100 lb. zinc and 2,398,607 lb. lead. Costs amounted to \$7.30 per ton. Profit was \$233,083, less \$41,158 for improvements. On No. 8 level, 7 ft. of ore assays 36.3% zinc. This was opened 120 feet.

Murray.—Miners Smelting & Refining Co. is reported as having been formed to build plant on Coeur d'Alene lake, Idaho, according to C. T. Kennan of Murray. Share-holders are to be owners of mines supplying ore to smelter. Reduction will be done at cost. All persons and mining companies owning mining claims or lands in Idaho, Oregon, Washington, Montana, and British Columbia may be shareholders in the company.

Yukon Gold Co.'s dredge on Prichard creek is working 24 hours daily. Bedrock is 30 ft. deep. Boulders have given no trouble, neither has cold weather. A. D. Hughes is manager.

MICHIGAN

Houghton.—Copper is accumulating in yards and docks due to shortage of freight-cars. Said to be enough metal to load three steamers. Navigation opens late in April.

South Lake Mining Co. reports for 1917 that income amounted to \$118,824, of which \$94,049 was from sale of copper. Expenses were \$203,539, \$195,850 being for mining. Excess of liabilities over assets is \$97,076, against \$2212 excess of assets a year previous. From May 1916 to December 1917, mill treated 68,388 tons of ore, yielding 754,433 lb. copper, equal to 11.03 lb. per ton. In December average was 14.5 lb., and in January 16 lb. Area of 166 acres adjoining on north is to be acquired for \$90,000. To pay for this and other indebtedness stock has been offered to shareholders at \$2 each.

MISSOURI

Granby.—M. K. & T. Mining Co., with C. A. Davis in charge, has resumed ore-dressing at its 500-ton mill, which has been closed by bad weather. Ore is mined at a depth of 240 feet.

Joplin.—Production of Missouri-Kansas-Oklahoma region last week was 6249 tons blende, 155 tons calamine, and 1077 tons lead, averaging \$53, \$35, and \$86 per ton, respectively. Total value was \$492,243, making \$2,613,155 for 10 weeks.

Neck City Mining Co. has been organized with capital of 1500 shares at \$100 par by B. C. Burgess and others of Joplin.

Hill Lead & Zinc Co. has been organized with capital of 300 shares at \$100 par by H. B. Wolcott and others of Joplin.

Seneca.—Considerable activity in this part of Newton county. Okmulgee Mining Co. has an 800-acre lease of Brown land, and is to drill it. J. H. McBrayer is in charge.

Silver Crown Mining Co., in charge of J. W. Thomas, is to start work here; also the Seneca Fault Mining Co., J. R. Case, superintendent.

Wentworth.—Zinc concentrate production of Georgette M. Co.'s two mines is 50 tons daily, rivaling all others in the Joplin district. Ore carries 7 to 20% blende. O. B. Henry is manager.

MONTANA

Butte.—Revival of Butte Metal Mine Workers' Union is being advanced by T. Campbell and W. F. Dunn, two strike leaders.

Butte-Copper Czar Mining Co. held its annual meeting on March 7. New York people have financed company, taking option on 80% of shares. Sunflower and Mayflower claims adjoining were purchased, making property 42 acres. Cross-cut is being driven at 300 ft. and shaft may be sunk to 500 ft. Morton Webber is consulting engineer.

Ore-reserves in Butte Copper & Zinc Co.'s mine, leased to Anaconda company are as under:

	Zinc ore	Manganese ore
Developed, tons	140,300	30,000
Zinc, per cent.	16.6
Lead, per cent.	6.9
Silver, ounces	8.5
Manganese, per cent.	38
Probable, tons	243,000	900,000
Zinc, per cent.	15
Lead, per cent.	5
Silver, ounces	6
Manganese, per cent.	38

Butte Copper & Zinc Co. has closed contracts with U. S.

Steel Corporation and others for 5000 tons of manganese ore. This is rhodocrosite, carrying 37% Mn and 7% SiO₂.

Elm Orlu Mining Co.'s suit for injunction restraining Butte & Superior Mining Co. from extracting ore from Rainbow vein in Black Rock claim of latter may be heard about middle of May.

Libby.—Rose Consolidated has increased capital to \$200,000, shares 10c. par. Ball-mill is to be added to 10 stamps. Reserves above add between No. 1 and 2 shafts are 3500 tons, assaying \$9 gold per ton. H. H. Phipps is president, and A. I. Goodell manager.

Marysville.—Barnes-King company has opened rich gold ore in its Gloster mine, hitherto producing only low-grade material.

St. Louis company is developing Drum Lummon ground to supply a 25-stamp mill.

Saltese.—Tarbox Mining Co. is to erect a 300-ton mill in the summer, according to manager, Richard Daxon. On 800-ft. level of mine over 700 ft. of openings have been made. Property has been examined by J. F. Davey, who reports that with proper equipment profits should be made. Water-power is also to be utilized. Ore carries lead and zinc.

Warm Springs.—Mountain States company has repaired its 250-ft. shaft to depth of 50 ft., and is installing machinery.

Frank Willard group is showing 4 ft. of lead-silver-zinc ore at depth of 100 feet.

Wolf Creek.—Rich silver ore is being sacked for shipment at Silver mine. Ore was found at 250-ft. depth. Extent of ore-shoot has not been determined.

NEVADA

Battle Mountain.—C. W. Burge states that San Francisco capital will erect a smelter and concentrator at this place to treat custom ore. Forty acres has been selected for site, and work is to be started within 60 days.

Gold Top Mining Co., in charge of J. J. Graf, is to install a compressor and machine-drills. A 36-ton ball-mill is crushing gold ore, but copper has been developed in promising quantities.

Goldfield.—Conferences have been held during past week by Florence Goldfield and Red Hills-Florence companies, relative to title to rich vein lately opened by latter at a depth of 400 ft. A survey of the workings was made, E. A. Byler representing the Florence, and J. B. Witt, of the Goldfield Consolidated, the Red Hills-Florence interests. It is reported the latter company has offered to purchase the Florence mine.

Jumbo Junior winze is down 80 ft. below 880-ft. level. Ore is from 18 to 24 in. wide, assaying \$100 per ton.

Ingalls mine in Tule canyon is shipping 50 tons of ore to smelter. Lessees estimate value to be \$300 per ton, mostly in silver.

Luning.—Operators are increasing the study of geological conditions here, in order that useless exploration may be eliminated. In 1917, about 25,000 tons of ore was shipped from this district, mostly mined by lessees. The Calavada is down 1200 ft., and is the deepest here.

R. B. Todd Mining Company's financial statement for period May 12 to December 31, 1917, shows receipts amounting to \$5451. Of this, \$746 was from ore production, balance from treasury shares, etc. Expenditure at mine was \$1365. Production cost \$511.

Luning-Idaho Mining Co.'s report for period September 1, 1916, to end of 1917 has been issued. Receipts totaled \$24,506, of which \$19,442 was from treasury stock. Ex-

penditure at the mine amounted to \$15,879, \$10,557 being for labor. The Hahn adit was extended 340 ft., and laterals driven over 200 ft. Leached formation and some sulphides were passed through, but the adit is not deep enough to enter the sulphide zone. Indications are encouraging. The Erickson adit is in 170 ft. in leached vein matter, but with considerable oxide ore. No. 1 Stockham adit was driven 143 ft., mostly in oxide ore, with stringers of rich sulphide ore. This is the best exposure on the property. Development is to be continued and treatment plant erected.

Wall Street mine in New York canyon is producing 30 tons of shipping ore daily, and employing over 75 men.

Mina.—Western Silver Mines Co. has prepared plans for first unit of 500-ton mill. Ore carries gold, silver, and lead. Development aggregates 6000 ft. Reserves are estimated as 200,000 tons. Directors are Utah people. Benjamin F. Tibby of Salt Lake City is consulting engineer.

Old Candelaria silver mine has been acquired by Frank Manson of Western Ore Purchasing Co. from W. S. Chafey. If machinery can be found a 150-ton mill is to be erected.

Nelson.—Techatticup company recently won in a dispute with Colorado-Nevada Mining & Milling Co. in Las Vegas Court over the right to use water in El Dorado canyon. The Colorado company has appealed on grounds of new evidence. On the basis of plenty of water. Techatticup is preparing for custom work and a two-compartment ore-bin of 150-ton capacity will be ready in a month.

Crown Queen mine has recently been sampled and examined preparatory to resuming under the same management as Techatticup. Crown Queen was shut-down June 30, 1916, on account of poor ore.

Cashman, Crozier, and Irwin have just completed operations on their claim where \$1500 ore was found for a time.

Allard's lease on Carnation mine is preparing for larger output. Tube-mill and centrifugal amalgamator are to be installed to treat high-grade ore.

Rand Mine & Milling Co. has shut-down its stamp-mill, due to lack of water, but is mining a small quantity of ore.

Pioche.—In suit of Virginia Louise Mining Co. v. Prince Consolidated Mining & Smelting Co., claiming damages for

examination involved interesting points, such as sampling, weight of ore in place, value, and bad faith. The Judge concluded in part. "I find that the taking of ore from the Virginia Louise ground was in accordance with the attitude of the management of the Prince Consolidated company, in difference of the rights of the smaller company, reckless disregard of the directors and stockholders of that company, an arbitrary and somewhat overhearing attitude toward it. A company the size and importance of the Prince should have kept a surveyor on duty when its work was near the line of its neighbor, and its failure to do that is in itself evidence of the disregard of its neighbor's rights, otherwise abundantly shown."

Combined Metals Co. is to start flotation plant leased from Amalgamated Pioche company. E. H. Snyder is in charge.

Tonopah.—Tonopah Mining Co. is sending dump ore to its plant at Millers and mine ore to the Belmont mill at Tonopah.

Cash Boy Consolidated development in winze below 1600 ft. is attracting attention. Vein is 5 ft. wide of good shipping grade.

In Gold Mountain and Gold Reef districts, 6 miles south of Tonopah, the Tonopah Divide has opened ore for 60 ft. at depth of 270 ft. Adjoining on south, Tonopah Gold Zone is to resume development. Adjoining latter is the Tonopah Gold Reef, which is considered to have a chance to get the Divide vein. Owners of the Divide have arranged to acquire adjoining property.

Production of district last week was 10,669 tons of ore valued at \$181,373, a considerable gain over previous week. Some February outputs are as follows:

Mine	Tons	Silver, oz.	Gold, oz.	Profit
Belmont	9,290	126,056	1,274	\$67,633
Jim Butler	1,860	13,071
Tonopah Mining	14,520	108,954	1,157	30,175

Tonopah Extension continues development of Murray vein on 1680-ft. level, where it was found last week.

Ohio vein in West End mine is 15 to 22 ft. wide, and grows in importance.

Virginia City.—Orebody discovered on 2300-ft. level of Union Con. three months ago has been cut at 2500 ft. It is same width as on 2300 and 2400-ft. levels, averaging \$30 per ton. Production is \$50,000 per month. Monthly dividend of 5c. per share will be paid April 1. Cross-cutting of vein from drift on 2500-ft. level has commenced.

Milling ore has been exposed at three points on the 2000-ft. level of the Con. Virginia. South of the 'Fair Jim' stope a promising vein is under development, and farther west a parallel vein is yielding ore at two points. Product is treated in Mexican mill, averaging \$18 to \$20 per ton. Output is to be increased. At present all ore is trammed to Union shaft from 2500-ft. level by compressed-air locomotives, but connections are being established that will permit delivery from 2000-ft. workings, where compressed-air locomotives are also in use.

Thompson.—Mason Valley smelter is reducing 1600 tons of ore daily, both furnaces in operation. Manager expects to be able to smelt 1800 tons per day in near future. Heavy shipments are coming from the Mason Valley, Bluestone, Nevada Douglas, and some small properties. Nevada Douglas contributed 2050 tons weekly and will soon increase this amount. Of the ore shipped, 40% assays 2.5 to 8.5% copper. Abundant coke supply has been secured for smelter.

Yerington.—Range of low hills west of Yerington is full of prospectors, and several leasing companies are producing steadily. Most of the ore is of shipping grade.

trespass, Judge M. R. Averill of District Court decided that generally the facts were as stated in complaint, and awarded plaintiff \$27,334.38. At one time Virginia Louise was controlled by Prince Consolidated. Latter admitted mining 1000 tons of ore, but former claimed about 1100 tons. The

NEW MEXICO

Mogollon.—Erection of main mill building of Socorro plant is under way. Building material is all on the ground and deliveries of machinery have started.

Oaks Co. is installing compressor at Deep Down mine. Meanwhile development is confined to No. 3 level.

Mogollon Mines Co. is increasing output. Custom ore is being refused, due to company's own requirements.

Examinations have been made of Enterprise mine at Cooney. It is understood that this property is to be opened.

OKLAHOMA

Galena.—Pumping operations in north-east Oklahoma field has practically drained ground as far north as Galena. Deep work—285 ft.—in the Wayland mine exposed a water-course and rich zinc ore but no water had passed through for some time. L. H. Phillips of Joplin is manager.

Miami.—Property alleged to be worth \$5,000,000 is subject of suit between N. S. Sherman and others and the Emma Gordon Mining, National Mining, and others. Fraud and collusion are charged, and an injunction against transfer of land is asked the court.

Picher.—Concentrate production of all districts last week totaled 3675 tons blende and 552 tons lead, valued at \$239,278.

Tri-State Mine Safety and Sanitation Association, organized here some months ago, is gaining in importance. Richard Jenkins, a well-known operator at Webb City, Missouri, was recently appointed assistant secretary.

Southeast Missouri Mining Corporation has put down 31 drill-holes to depth of 185 ft., exposing ore 35 ft. thick. Two shafts are being sunk. A 300-ton mill will be completed early in June. O. C. Whitener is president.

Picher-Oklahoma Mining Co. is to erect an 800-ton mill. R. P. McReynolds is general manager.

OREGON

Ashland.—M. G. Womack, H. H. McCarthy, and Carl Jeschke, of Medford, are developing a promising asbestos deposit in Siskiyou mountains south of Ashland, which is within 5 miles of shipping. Samples show a high-grade long-fibre asbestos.

Grants Pass.—Contract has been let for erection of reduction-plant at Alameda copper-gold mine on Rogue river, 27 miles below Grants Pass. Concentrator is to be 200-ton capacity, and blast-furnace of 150-ton capacity. Cost will total \$200,000. About 500 hp. will be required to operate machinery, which will be furnished by the local electric power company. Alameda mine is said to be better developed than any mine in southern Oregon; due partly to its favorable situation, being in a narrow canyon of the river, giving a natural transverse section of lode to depth of 500 ft. Development consists of 8000 ft. of underground working, consisting of 5 levels, supplemented by a 500-ft. vertical shaft. These open ore for 1000 ft. horizontally and 800 ft. vertically. Reserves are estimated to be worth \$6,000,000.

SOUTH DAKOTA

Deadwood.—Gold Reward company has installed a new 100-ton Portland filter. It is used for preliminary wash of the 'blue' sulphide ore before cyaniding. Cake from filter is mixed with oxidized ore and treated by cyanide. Results are satisfactory.

Lead.—Homestake high-pressure air-compressor has been changed to electric drive, and changes from steam are also being made at Brig hoist. Other equipment will be motor driven as soon as possible. A 90-ft. raise has been started

at Ellison hoist. This will have a diameter of 30 ft., lined with concrete. When completed it will be used for coal storage. The bin is connected with a lower tunnel by a chute, and coal will be transported to the central steam plant by means of conveyor-belt.

Homestake Mining Co. pays 50c. per share on March 25.

TEXAS

Benjamin.—Brazos-Wichita Copper Co., which has been conducting extensive development in this copper area, exposing a large quantity of high-grade ore, has let the contract for the construction of a smelter at Benjamin. It has been known for over 50 years that copper existed here. Metal is in the form of nodules, ranging in size from a pea to a hen's egg, found in layers in clay formation. Separation of metal from clay has been one of the most difficult problems. From time to time during many years, efforts have been made to develop this deposit. In the early 'eighties several shafts were sunk and open-cuts made, by which considerable copper ore was obtained, but the long overland haul necessary to get the ore to market made the venture a failure. In ravines and water-courses that traverse the area there were found in earlier days great piles of the copper nodules that had been separated from the clay. Several hundred tons of this copper was removed from the accumulated deposits and hauled long distances to the nearest railroad for shipment. Besides the Brazos-Wichita company, there are several other concerns operating in this part of Texas.

UTAH

Alta.—In original suit of Monetaire Mining Co. v. Columbus-Rexall Consolidated Mines Co. asking permission to use 1200-ft. level of defendant in order to reach part of its property, Monetaire company lost. In recent appeal, the Monetaire is entitled to use the level, and a new trial was ordered. Right of eminent domain was the deciding factor in the judgment.

American Fork.—All the old officers of the Pacific Gold M. & M. Co. were re-elected recently. J. L. Craig is president, James Chipman Jr., vice-president and treasurer, H. C. Johnson secretary, with A. B. Stevenson and A. K. Thornton additional directors. From February to April 1917, the mine was leased to the Fissures Exploration Co., and from that time to June 1919, by the American Fork Exploration Co. If \$50,000 is not paid in royalties or otherwise by this date, the lease extends for 5 years more. So far the Pacific company has received \$12,300, \$3363 of which was paid during the past 11 months. Weather and strikes hindered operations during the period. Above the adit-level are 7 months' ore-reserves for the 150-ton mill.

Cisco.—Utah Placer Mining Co. is to resume work at its Beaght claim, 22 miles from this place. Plant is capable of treating 125 yards of gravel daily at cost of 24c. per yard. Gold content is said to vary from 75c. to \$1 per yard.

Eureka.—Black Jack claims of Empire company are encouraging, as at depth of 1800 ft. a 3-ft. vein of good copper ore was cut recently.

Eureka King company has suspended work until more money is secured.

Gold Hill.—Western Utah Copper Co., operating in Deep Creek district, held its annual meeting at Salt Lake City on February 21. J. E. Bergh was selected as general manager. During 9 months ended December 31, 1917, metal yield was 70 oz. gold, 150,767 oz. silver, 371,418 lb. lead, and 1,710,984 lb. copper. One dividend of 7½c. per share, equal to \$37,500, was paid on February 15, 1918. Shipments are now 200 tons daily.

Pole Star Copper Co. has opened shipping ore at depth of 300 ft. This has aroused interest in the district.

Park City.—Ore and concentrate shipments during February amounted to 7250 tons, against 10,547 tons in January. Weather was mostly responsible for the shrinkage. Silver King Coalition sent out 1896 tons, Ontario Silver, 1933; Judge M. & S., 1058; and Silver King Con., 796 tons.

Daly-West Mining Co.'s control has passed to Judge Mining & Smelting Co. Better results are expected from new management. No dividends paid since 1913.

Tintic.—Ore production of the district during February amounted to 16,400 tons from Eureka district, 7000 tons from Mammoth district, and 5600 tons from Silver City. Tintic Milling Co. at Silver City received over 5000 tons.

Tintic Coalition mine is to be re-opened at an early date, Frank Thornburg having secured money for this.

Tintic-Delaware is preparing its mine for steady production when roads are passable. Good lead-silver ore is ready for extraction. Andrew Madsen is superintendent.

WASHINGTON

Metalline.—Lead & Zinc Co.'s 175-ton mill, etc., is to be sold by auction on March 28 to satisfy creditors who claim \$139,179.

Northport.—Electric Point Mining Co. is to erect an aerial tram of 20-ton hourly capacity costing \$40,000. This will connect the main shaft and the road at Leadpoint, 2½ miles apart. Shaft is now 700 ft. deep. Roy A. Young is manager.

CANADA

British Columbia

Ainsworth.—No. 3 adit of Florence Mining Co. shows 300 ft. of ore, 100 ft. of which assays high in lead and silver. This is at depth of 700 ft. Mill is treating 100 tons per shift. F. R. Wolfe is president.

Britannia Beach.—Howe Sound Co. has declared initial quarterly dividend of 5%, payable April 15, amounting to \$100,000. Company controls Britannia Copper Mining Company.

Kaslo.—Manganese deposits of A. G. Larson of Spokane and A. J. Curle of Kaslo have been sold to Seattle people, probably the Pacific Coast Steel Corporation, for \$160,000. One deposit contains, as far as opened, 9500 tons of 43% ore.

Nelson.—Consolidated Mining & Smelting Co. may erect a concentrating plant here, according to a U. S. Consular report, February 14.

Silverton.—Standard Silver-Lead company has cut several feet of good ore between No. 5 and 6 adits, at depth of 1000 feet.

MEXICO

Jalisco

Ameca.—Magistral Mining Co. has resumed operations, and is treating 100 tons of ore daily. Mill includes Marcy ball-mill, 3 K. & K. flotation machines, Dorr thickener, etc. Ore carries chalcopryite.

Etzatlán.—Amparo Mining Co. continues regular operations and is treating 10,000 tons of silver-gold ore monthly. Tests with flotation have been satisfactory.

Magdalena.—Cinco Minas Co. is treating 500 tons of ore daily. Little time has been lost by the revolution.

Sonora

Cananea.—Greene-Cananea produced 3,960,000 lb. copper in February, against 3,130,000 lb. in January, 1,650,000 lb. in December, and 5,100,000 lb. a year ago.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

W. B. Fisher is at Austin, Nevada.

W. J. Loring is at Mill City, Nevada.

Bulkeley Wells is at Picher, Oklahoma.

J. B. Tyrrell has returned from London to Toronto.

E. Jacobs has gone from Victoria, B. C., to Seattle.

W. de L. Benedict has arrived here from New York.

J. D. Hubbard has returned to Paradise, Butte county.

W. B. Devereux Jr. is Captain of Aeronautics, U. S. Army.

E. J. Atckison has returned to California from the Amparo mine, in Jalisco, Mexico.

L. E. Grant, assistant manager for the Braden Copper Co., has returned to Sewell, Chile.

R. N. Bell, Mine Inspector for the State of Idaho, is visiting the Oklahoma zinc region.

W. B. Ingalls has been re-elected president of the Mining and Metallurgical Society of America.

John F. Coats, mining engineer to the Granby Consolidated company, is here from Vancouver.

Samuel H. Dolbear has been summoned to Washington for consultation with the War Industries Board.

George H. Short, representing the Grasselli Chemical Co., is investigating the chrome deposits of California.

Frank W. Spear, of Las Vegas, Nevada, who is interested in the Chicago-Nevada Eldorado Co., is at Chicago.

Curtis H. Lindley has gone to Washington to argue the Jim Butler v. West End case before the Supreme Court.

Clyde M. Becker has enlisted as Army Y. M. C. A. Secretary for home service with headquarters at Camp Cody.

Charles Wright has been appointed manager of the Keweenaw copper mine, Houghton, in place of William Uren.

Charles R. Van Hise represented the University of Wisconsin at the semi-centenary of the University of California.

L. D. Ricketts is attending the semi-centenary of the University of California as a representative of Princeton University.

James Park, professor of mining in the University of Otago, New Zealand, is examining molybdenite properties in Queensland, Australia.

T. T. Read, of the New Jersey Zinc Co., is going to Washington to work in a newly-organized planning division of the Ordnance Department.

A. B. Richmond will take charge of the Reiniger-Freeman operations at San Xavier, Arizona, succeeding Robert J. Ward, who is now foreman.

W. J. Turner, smelter superintendent for the Braden Copper Co., Chile, has joined the American army. W. L. Stevens is now acting superintendent.

Gomer P. Jones, resident manager for the Hedley Gold Mining Co., has returned to Hedley, after undergoing a successful operation at Vancouver, B. C.

W. Sinclair Brown, metallurgist to the Redjang Leborg company in Sumatra, passed through San Francisco on his way to Glasgow, to engage in patriotic service.

Will H. Coghill, of the U. S. Bureau of Mines, will deliver a series of lectures on the 'Molecular Physics of Flotation' from March 25 to 29 inclusive at 4 p.m. each day in the College of Mining of the University of California.

F. A. Fahrenwald, consulting mining engineer and metallurgist, of Cleveland, Ohio, will be in the West from about March 25 to May 10, two weeks in New Mexico and Arizona, two in California and Nevada, and the remainder of the period in the North-West.

THE METAL MARKET

METAL PRICES

San Francisco, March 19

Aluminum-dust (100-lb. lots), cents per pound.....	90
Aluminum-dust (ton lots), cents per pound.....	80
Antimony, cents per pound.....	13 1/2
Antimony (wholesale), cents per pound.....	13 1/2
Electrolytic copper, cents per pound, in carload lots.....	23 1/2
Electrolytic copper, cents per pound, in small quantities.....	24 1/2
Pig-lead, cents per pound.....	7 1/2
Platinum, soft and hard metal, respectively, per ounce.....	\$108—116
Quicksilver, per flask of 75 lb.....	\$115
Spelter, cents per pound.....	10
Zinc-dust, cents per pound.....	17 1/2

ORE PRICES

San Francisco, March 19

Antimony, 45% metal, per unit.....	\$1.10
Chrome, 34 to 40%, f.o.b. California, cents per unit.....	60—70
Chrome, 40% and over, cents per unit.....	90—105
Magnetite, crude, per ton.....	88—10
Manganese, 40%, f.o.b. Chicago, cents per unit.....	83
Tungsten, 60% WO ₃ , per unit.....	\$24
Molybdenite, per lb., 85% MoS ₂	\$2.15

The tungsten market is quiet, due to transportation difficulties.

Above quotation for molybdenite is only nominal, as the principal buyers are out of the market. Japanese is being offered at large concessions.

Calced magnesite is quoted at \$35 per ton, f.o.b. shipping point

Refractory ore and brick market is discussed in 'The Iron Age' of March 7. Price of magnesite brick has been reduced from \$135 to \$125 per ton, due to better railroad conditions. Chrome situation is considered serious, owing to shortage of ore and winter affecting mining operations.

Wolfram prices in Australia are \$12.60 per unit for 65% ore, as fixed by the Commonwealth government.

EASTERN METAL MARKET

(By wire from New York)

March 18.—Copper is dull and easier. Spelter is inactive and weak. There are no quotations for platinum.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver

Date	1916	1917	1918	Average week ending
Jan. 13.....	86.50			86.62
" 14.....	86.50			85.93
" 15.....	86.50			85.48

Apr.	64.37	72.51	
May	74.27	74.61	
June	63.04	76.44	

Currency reform of China consists of two main parts: (1) unification of silver currency, and (2) redemption of depreciated notes. Fineness, weight, and form of silver coins are to be uniform, and any coins in circulation will be withdrawn and re-coined. Silver subsidiary coins to replace the small ones now in use are to be made. To do this a large sum of money must be borrowed. The 'Far Eastern Review' hopes to see currency reform at no distant date.

COPPER

Prices of electrolytic in New York, in cents per pound

Date	1916	1917	1918	Average week ending
Jan. 13.....	23.50			23.50
" 14.....	23.50			23.50

May	30.02	31.69	
June	27.47	32.57	

Nichols Copper Co., which has a great refinery at Laurel Hill, New York, is reported to have increased refining charges 33 1/2%.

Australian copper production is to be bought by the British Ministry of Munitions to June 30, 1918. Sum involved will be \$2,150,000. Maximum quantity to be delivered under this contract is 20,000 tons, and the minimum 15,000 tons. Price for electrolytic and Wallaroo copper is \$108 per ton (23.1 cents per lb.), and \$106 (22.7 cents per lb.) for other brands, f.o.b. Sydney. Copper Producers Association accepted the offer on February 6.

LEAD

Lead is quoted in cents per pound, New York delivery.

Date	1916	1917	1918	Average week ending
Jan. 13.....	7.25			7.00
" 14.....	7.25			7.00
" 15.....	7.25			7.08
" 16.....	7.25			7.10

TIN

Prices in New York, in cents per pound.

Date	1916	1917	1918	Average week ending
Jan. 13.....	41.76	44.10	85.13	7.87
" 14.....	42.60	51.47	85.00	8.00
" 15.....	50.50	54.27		8.32
" 16.....	51.49	55.63		8.32
" 17 Sunday.....				8.32
" 18.....	49.10	63.21		8.32
" 19.....	42.07	61.93		8.32

Tin imports to February 28 amounted to 7740 tons, compared with 10,023 tons in the two months of 1917. Straits shipments fell off 2531 tons, and from Banks and Biliton 1260 tons.

Tin business of Hongkong in 1917 was briefly as follows: Stocks on hand, at beginning, 3600 tons; stocks at close, 1500 tons; exports to China and Japan, 1500 tons; to Europe, 2000 tons; to United States, 7138 tons. Of course this great port is only a transfer point for tin, none being produced there.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date	1916	1917	1918	Average week ending
Jan. 13.....	115.00			110.00
" 14.....	115.00			110.00
" 15.....	115.00			110.00
" 16.....	115.00			110.00
" 17 Sunday.....				110.00
" 18.....	115.00			110.00
" 19.....	115.00			110.00

Monthly averages	1916	1917	1918
Jan.	22.00	81.00	128.00
Feb.	295.00	126.25	118.00
Mar.	219.00	113.75	
Apr.	141.00	114.50	
May	90.00	104.00	
June	74.70	85.50	

Mexican virgin metal is readily obtainable at \$115 per flask, ex warehouse, New York.

Eastern Metal Market

New York, March 13.

There has been little change in the general condition of the markets since a week ago; they are all practically devoid of interest and are inactive, excepting tin.

Higher fixed prices for copper are being urged.

Tin is in good demand for future delivery, but spot metal is still unobtainable.

Lead is less active, but the tone is firm.

Zinc is lifeless and weaker.

Antimony is lower.

The absorbing topic in steel circles is the revision of the fixed price-schedule due April 1. On Wednesday, March 20, a conference on this matter will take place in Washington between steel-makers and the War Industries Board. The diverse interests of the small producers, who must have a high price, and the largest integrated companies, who can go on the present basis, are now sharply accentuated. Pig-iron and steel output is increasing, due to more favorable weather; but the 1918 production will probably not equal that of 1917. Government requirements for the last half of 1918 are developing. For shell-steel probably 2,500,000 tons is the estimated need, compared with 1,500,000 tons in the first half. The Government also soon will buy 150,000 cars and 2500 locomotives.

COPPER

The principal topic in copper circles is the recognition that a strong attempt is on foot to advance the present Government price of copper of 23.50c. to at least 25c. per lb. by June 1, when the present arrangement expires, or before if possible. It is contended that costs of production have advanced in many departments several cents per pound, and to maintain top production a higher price for the metal is necessary. Opinion among dealers in New York varies, some agreeing that a re-adjustment is necessary, others contending that it is not, and that it would be unfair. Transportation conditions are better everywhere, and it is estimated that the output of the smelters by the end of March will be at the rate of 200,000,000 lb. per month. Added to this is the fact that imports of raw metal are increasing; those for 1918 will probably approximate 23,000 to 25,000 tons per month, contrasted with 20,000 tons per month in 1917. The Mexican output will probably be large, as well as that from other foreign sources. The fixed prices in the London market continue unchanged at £125 for spot electrolytic, and £121 for futures, which have ruled many months. Copper exports for February, to the 20th, were 18,834 tons, so far reported.

TIN

There has been a good demand during the past week for tin for future delivery but spot metal of all grades is as scarce as ever. For futures, sellers have been few and some have withdrawn from the market entirely. The result has been that buyers have bid up the market on themselves so that future shipment from the East has sold as high as 75c. per lb. In the last few days there have been no offers of future Straits tin from England. Some buyers have desired to purchase, but there have been no sellers. An unusual condition developed yesterday (March 12) which, in the memory of a large dealer in New York, has never occurred before, namely, it was impossible on that day to obtain a price of Straits tin for any position. There exists now an annoying delay in cablegrams, which is interfering with business. It takes four days to send a message over and get a reply. Arrivals to March 12, inclusive, were 997 tons. On

that day the quantity afloat was reported as 6300 tons. The London market is higher than last week. Spot Straits was quoted yesterday at £322 10s., against £319 per ton a week ago.

LEAD

There is little to say about the lead market. The tone is firm and steady, but demand has lessened considerably. There has been no change in prices. Lead for early delivery is held at 7.25c., New York, by both the American Smelting & Refining Co. and by independents. The St. Louis price is 7.10c. per lb. There is very little demand for spot lead, even less than a week ago. One dealer reports no demand at all, while another sold spot lead at 7.87½c., New York, in the last day or two. The spot market is quoted at 7.50 to 7.75c., New York. Transportation conditions are much better, this being one cause of the easier market. The trade as a whole is 'watchfully waiting', and exhibiting no anxiety.

ZINC

The only strong feature of the zinc market is the demand for grade A. This is considerable, for it is the principal kind of metal that the Government needs for munitions. The supply of this is now about balanced by the demand. While the output is large, this has been partly because of the re-distilling of lower grades, such as prime Western. A scarcity of grade A is not unlikely before long, on account of probable large Government munition orders in the near future. The price for grade A is fixed at 12c. per lb. So far as prime Western is concerned the market is flat, despite the estimate and probability that smelters' output has declined to 50% of capacity. Demand continues light. Sales have comprised only small lots here and there. Some of them have gone at as low as 7.50c., St. Louis, or 7.75c., New York, which seems to be the market for early delivery. Part of the sales at this low level have been for cash, which, however, is not customary. Some producers and dealers refuse to quote under 7.62½c., or even 7.75c., St. Louis. Sheet-zinc is quoted at the official price of 15c. per pound.

ANTIMONY

The market is quiet, demand outside the Government being negligible. The metal has sold during the past week at 13.25c., New York, duty paid, which seems to be the present level.

ALUMINUM

Since the Government price was fixed last week at 32c. per lb. for No. 1 virgin metal 98 to 99% pure, for 50-ton lots, there have been no developments. Quotations for smaller lots are unobtainable in the absence of official news.

ORES

Antimony: Buyers would pay about \$1.75 per unit, but there is not much ore being offered, shipping conditions interfering with transport from South America.

Molybdenum: In the absence of any demand from large buyers the market is difficult, or practically impossible, to quote. Offerings of Japanese ore at concessions are not attracting any attention, according to one dealer.

Tungsten: High-grade scheelite has sold at \$24.50 per unit in 60% concentrate, against \$26 formerly. This is for spot delivery. The market has been generally quiet, however. Because of embargoes and the urgent need of ore by certain works, shipments of carloads have been made by express. Ores in general range from \$20 to \$24 per unit, depending on the grade. Ferro-tungsten is unchanged at \$2.25 to \$2.35 per lb. of contained tungsten.

Company Reports

RAY HERCULES COPPER CO.

PROPERTY: disseminated copper deposits adjoining Ray Consolidated at Ray, Arizona, well developed, and a 1500-ton mill ready for ore treatment.

OPERATING OFFICIALS: C. E. Addams, general manager; J. M. Callow, consulting metallurgist; Bradley, Bruft & Laharthe, construction engineers.

FINANCIAL STATEMENT: for period from beginning of operations to October 31, 1917, shows that at the end of June 1917, cash amounted to \$544,679. Company owns nearly 100% of shares in Arizona Hercules Copper Co. As production is to commence early in 1918, the next report will show revenue and expenditure items.

DEVELOPMENT: No. 1 shaft, 15 ft. 10 in. by 8 ft. 10 in. over all, is 862 ft. deep, and is to be sunk to 930 ft. By October 31, 1917, 1600 ft. of driving had been done from this shaft. Drifts are timbered with 12 by 12-in. lumber. Carbonate ore was cut at depth of 55 ft. continuing to 75 ft.; then again at 255 ft.,

gravity oil per kilowatt-hour. Each engine is direct connected to a 900-kw. General Electric generator. Transmission-line to mine is nearly six miles long.

At the mill the main bin holds 2500 tons. A Merrick weightometer records continuously the ore carried on three 16-in. belt-conveyors, which deliver direct to three No. 86 Marcy mills of 500 tons capacity each. There are also three 6-ft. Hardinge mills. Ore-dressing is done by 12 roughing and 3 finishing Overstrom tables, 9 Dorr classifiers, and 36 roughing and 6 cleaning Callow flotation cells. Two 26 by 36-in. Boston type Connorsville blowers serve the flotation plant. Concentrate will be dried by three 11 ft. 6 in. by 8 ft. Oliver filters. Capacity of mill is 1500 tons daily, giving a recovery of 80%. Tailing area can easily hold 100,000,000 tons of residue.

TONGKAH HARBOUR TIN DREDGING CO.

PROPERTY: tin-dredging concession of 5350 acres in harbor of Tongkah, Puket, Slam. Five boats are operating.

OPERATING OFFICIALS: E. T. Lewis, general manager; A. McEwan, secretary.

FINANCIAL STATEMENT: for years ended September 30 are as follows:

	1917	1916	1915
Revenue	£144,845	£114,993	£123,260
Net profit	67,923	40,808	40,336
Dividends	37,500	60,000	22,500
Total dividends		345,000

SUMMARY OF OPERATIONS:

	1917	1916	1915
Ground dredged, cubic yards..	3,682,550	3,363,750	2,968,600
Average tin content, cents...	18.86	16.40	19.92
Cost, cents	8.80	9.26	10.00
Tin oxide (70% metal), tons..	1,188	1,076	1,262

Output to date is 9767 tons of oxide, valued at £1,026,000.

CONSOLIDATED INTERSTATE-CALLAHAN MINING CO.

PROPERTY: zinc-lead claims in Coeur d'Alene region, Idaho.

OPERATING OFFICIALS: C. W. Newton, manager; D. F. Haley, consulting engineer.

FINANCIAL STATEMENT: for 18 months ended December 31, 1917, income from ore and concentrate was \$4,117,597, plus \$62,335 from sundries. Operations, improvements, etc., cost \$1,854,055, leaving a profit of \$2,323,876. Surplus at June 30, 1916, was \$733,509 net, making \$3,109,386 available. After paying dividends, surplus at end of 1917 was \$551,941.

DIVIDENDS: \$2,557,445 was paid during the period, making a total of \$6,509,860 since April 1915, or 140% on the par value (\$10) of shares.

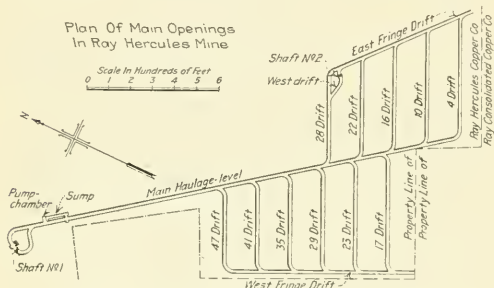

DEVELOPMENT: covered 9816 ft., and 60,000 cu. ft. of stations and skip-chutes. The 3-compartment shaft was completed to No. 8 level, 850 ft. below main, or No. 4, working adit. Shaft is being continued to No. 9 level. A fine orebody was developed on No. 7, and No. 8 has opened the same high-grade ore. Reserves above No. 7 are estimated at 310,000 tons.

PRODUCTION: there was delivered to mill 226,281 tons of ore. Of this, 17,315 tons, assaying 48% zinc, and 3335 tons, assaying 47% lead and 18 oz. silver, was shipped direct. Mill treated 186,441 tons, averaging 23.4% zinc, 6% lead, 2.3 oz. silver, and 6% iron.

COSTS: mining and milling were \$5.901 per ton mined, and of shipping product, f.o.b. cars at rail, \$14.13 per ton.

IMPROVEMENTS: a contract was made with Minerals Separation for installing its apparatus; adjoining property was acquired; buildings were erected; grinding department was enlarged; a cable-tram to reclaim tailing was installed; and considerable research was done.

Plan Of Main Openings
In Ray Hercules Mine

continuing to 385 ft. No. 2 shaft, 15 ft. 4 in. by 8 ft. 8 in. over all, is 543 ft. deep. At 521 ft. the main haulage-level was started. From this shaft 2300 ft. of work was done to end of October. Sulphide ore appeared at 225 ft., continuing to 345 ft. From haulage-drifts of both shafts, laterals are being driven under the present developed orebodies. Reserves are estimated at 9,500,000 tons of 1.77% ore.

Tracks on main levels are of 45-lb. steel rails, 18-in. gauge, and on laterals, 35-lb. rails. Ore-cars are hopper-bottom, automatic dump, of 38 cu. ft. capacity, drawn by four-ton Westinghouse locomotives driven by 125-volt direct-current motors. Such locomotives are an innovation for underground work.

Reinforced concrete bins of 400 tons capacity each were constructed on No. 1 and 2 levels of No. 1 shaft.

NEW PLANT: At main hoisting-plant the head-frame is of steel, 110 ft. high. It carries two 120-in. sheaves for main haulage ropes. Automatic skips will carry five tons of ore. Main electric hoist has two drums, 7 ft. diameter by 72-in. face, each grooved for 1250 ft. of 1½-in. rope. Capacity is 300 tons per hour. Nordberg is the maker. An Ingersoll-Rand, Rogier type, air-compressor of 3000 cu. ft. capacity is at work. Complete shops are in operation.

Coarse-crushing plant contains one No. 8 Gates type K crusher and one set of 54 by 26-in. Traylor rolls. Each crusher can reduce 150 tons per hour to 24-in. size, rolls corresponding. Product is carried on 36-in. belt to sampling-plant and main ore-bin of 5000 tons capacity.

From bin, ore is loaded into railroad cars and taken to the mill, six miles from the mine on the Gila river, at a place called Belgravia. Here is a power-house containing three Diesel engines made by McIntosh & Seymour. Each has 6 cylinders and has a capacity of 1045 hp., using 0.64 lb. of 16

INFORMATION FURNISHED BY MANUFACTURERS

ECONOMY IN PULVERIZED COAL

In view of the present coal-shortage and the high cost of fuel, the results secured in a recent 24-hour test of a 150-hp. Brownell horizontal return-tubular boiler, at the demonstrating plant of the Powdered Coal Engineering & Equipment Co., Chicago, when fired with powdered coal, is of special interest to those developing steam with coal. The duration of the test was exactly 23½ hr., and on both days, December 27 and 28, 1917, the temperature outside averaged about zero Fahrenheit. Members of the Chicago City Smoke Inspection Bureau, the City Efficiency Engineer, as well as representatives of several public utility corporations, steam railroads, and the

The proximate and ultimate analyses of the coal are given in Table I.

TABLE I		PROXIMATE ANALYSIS	
		Dry %	As burned %
Moisture	2.94	2.94
Volatile matter	37.61	36.49
Fixed carbon	36.51	35.42
Sulphur	3.79	3.71
Ash	22.09	21.44
		100.00	100.00

FIG. 1. CARBON DI-OXIDE CHART, 24-HOUR TEST, BURNING POWDERED COAL

technical press, were in attendance. The boiler furnace was served by two 12-in. Pruden coal carbureters. The conditions of the test were such as correspond to regular work, and not to special engineering refinements. The coal burned was a high-ash (22.09%) La Salle county, Illinois, screening, with a heating value of 10,158 B.t.u. on a dry basis. The coal was dried and pulverized in the demonstration plant of the Powdered Coal Engineering & Equipment Co., this coal-preparation unit having a capacity of 60 tons of pulverized fuel per day. As burned under the boiler, the coal dust had a moisture content of 2.94%. A screening test showed that 98.8% passed through a 100-mesh screen and 90.5% through a 200-mesh screen.

ULTIMATE ANALYSIS		Dry %	
Carbon	60.86	60.86
Hydrogen	4.32	4.32
Nitrogen	0.99	0.99
Oxygen	7.95	7.95

Ash	22.09	22.09
		100.00	100.00

In Table II are given the results and data of the test, in the short form of the A. S. M. E. code of 1912.

TABLE II

DATA AND RESULTS OF EVAPORATIVE TEST

1. Test of Brownell tubular boiler, at the plant of the Powdered Coal Engineering & Equipment Co., 2401 Washington boulevard, Chicago, to determine evaporation.
2. Kind of furnace.....Special construction
3. Grate-surfaceGrate absent; fired by two Pruden carbureters, 12 in.
4. Water-heating surface...1504 sq. ft.
5. Superheating surface...None
6. DateDecember 27-28, 1917
7. Duration23½ hr.
8. Kind and size of coal...LaSalle county, Illinois, screening, pulverized 90.5%, through 200-mesh; 98.8% through 100-mesh

AVERAGE PRESSURE, TEMPERATURES, AND OTHER ITEMS

9. Steam-pressure by gauge..... 135.1 lb.
10. Temp. of feed-water entering boiler... 145°F.
11. Temp. of escaping gases leaving boiler. 609.8°F.
12. Force of draft in fire-box..... 0.15 in.
13. Per cent of moisture in steam..... 0.95

TOTAL QUANTITIES

14. Weight of coal as fired..... 17,625 lb.
15. Per cent of moisture in coal..... 2.94
16. Total weight of dry coal consumed... 17,107 lb.
17. Total ash and refuse..... 3,679 lb.
18. Per cent of ash and refuse in dry coal.. 22.09
19. Total weight of water fed to the boiler..117,835 lb.
20. Total water evaporated, corrected for moisture in steam.....116,715 lb.
21. Total equivalent evaporation from and at 212°129,554 lb.

HOURLY QUANTITIES AND RATES

22. Dry coal consumed per hour..... 735.7 lb.
23. Dry coal per sq. ft. of grate surface per hour
24. Water evaporated per hour, corrected for quality of steam..... 5,020 lb. per hr.
25. Equivalent evaporation per hour from and at 212°F..... 5,572 lb. per hr.
26. Equivalent evaporation per hour from and at 212°F, per sq. ft. of water-heating surface

CAPACITY

27. Evaporation per hour from and at 212°F..... 5,572 lb.
28. Boiler hp. developed..... 162
29. Rated capacity, in evaporation from and at 212°F, per hour..... 5,175 lb.
30. Rated boiler hp..... 150
31. Per cent of rated capacity developed... 108

ECONOMY RESULTS

32. Water fed per pound of coal fired..... 6.69 lb.
33. Water evaporated per pound of dry coal. 6.84 lb.
34. Equivalent evaporation from and at 212°F, per pound of dry coal..... 7.59 lb.
35. Equivalent evaporation from and at 212°F, per pound of combustible..... 9.73 lb.

EFFICIENCY

36. Calorific value of 1 lb. of dry coal..... 10,158
37. Calorific value of 1 lb. of combustible.. 13,039
38. Efficiency of boiler, furnace, and grate. 72.5%
39. Efficiency of boiler and furnace..... 72.5%

COST OF EVAPORATION

40. Cost of coal per ton of 2240 lb. delivered in boiler room (including drying and pulverizing) \$4.28
41. Cost of coal required for evaporating 1000 lb. of water from and at 212°F.... \$0.2793

Fig. 1 is a reproduction of the CO₂ chart obtained over the period covering the duration of the test. It will be observed that the CO₂ content is much higher than the average in the

FIG. 2. SIMMANCE-ABADY COMBUSTION RECORDER

usual standard practice. It is certain that such a chart has never before been obtained in any type of steam-boiler practice over such a long period of time, under operating conditions that are normal and that can be duplicated by ordinary labor any day in the year.

The conditions under which the test was made were unfavorable from the standpoint of thermal efficiency, making it appear probable that under continuous service in ordinary weather the high boiler and furnace efficiency, namely, 72.5%, easily might be exceeded. The powdered coal was lighted under a cold boiler three hours before the test was started, the average temperature of the air fed with the powdered coal being approximately 4° F.

Bituminous coal, with 18% ash, under ordinary conditions of grate-firing, will usually be found to produce an ash containing from 16 to 18% of combustible. The ash and slag produced in the test given above contained only a trace of combustible, actually less than 0.1%. It is evident, then, from a consideration of the unavoidable losses in grate-fired practice due to unburned material, that the burning of powdered coal by the carburization process represents a saving in this instance of $0.17 \times 0.22 \times 10,158 = 380$ B.t.u. per pound of coal, or a saving of 3.74% of the heating value of the coal, due only to the fact that the coal is completely burned.

It may be affirmed that the average modern plant, using the same grade of coal, would not, under ordinary operating conditions, realize a boiler and furnace efficiency of more than 55 to 60%, as against the efficiency of 72.5% that was obtained with powdered coal. Every precaution was taken to insure accuracy. Horse-power developed was recorded by a General Electric flow-meter; water evaporated checked by weighing water delivered; percentage of CO₂ in flue-gases recorded by a Simmance-Abady combustion recorder, checked at intervals by analyses in the Orsat apparatus; and the flue-gas temperature measured by a recording thermo-couple.

OUR homage—our enthusiastic respect and profoundest gratitude—goes forth to the gallant men that are fighting for us at the front of battle. May they be sustained by the traditions of the English-speaking peoples, and of the French, to the full accomplishment of their devoted purpose.

AGAIN the Hearst press has shamed itself by commercializing the emotional stress of the moment by sensationalism, searing the souls of good citizens by flaring headlines that exaggerated the first news from the front. On the Monday morning Hearst's organ of misinformation could find no time to publish a thoughtful editorial on the one subject of the hour; all it could do was to give its readers a scholarly, scientific, and absorbing article on the local distribution of milk!

QUOTATIONS for silver have risen sharply during the past week. At the time of writing the New York price is 92½ cents, but the actual selling price in San Francisco is three cents higher. The impending legislation for coining the stock of silver in the Treasury and the demand from the Orient are the causes of this rise. It is estimated that 1,500,000 ounces is bought weekly in London for the Allies and for India. About 8,000,000 ounces is being exported weekly from the United States. If the minting of the \$200,000,000 of silver in the Treasury is legalized, followed by purchase of the metal to take its place, we may expect a stable price at about a dollar per ounce.

WHAT share university men in England are taking in the War is indicated by the figures quoted by the Archbishop of York on the occasion of his recent visit to Harvard. He said that the number of undergraduates at Oxford had decreased from 3200 to 300, while at Cambridge the reduction was from 3600 before the War to 400 at the present time. Such students as are in residence now consist of those that have been rendered unfit for service by reason of wounds or previous physical disability. The college-buildings are being used for the purposes of the War. "The home of lost causes" has given her life-blood in behalf of the Cause to which we also are committed, and our own universities now are following the noble leadership of the older centres of learning across the Atlantic. By this personal devotion

to a common purpose there will be forged links of friendship stronger even than the common language and the common tradition of the Anglo-Celtic race.

THAT the Germans intend to despoil France of her iron resources, if they can, has been indicated recently by the disclosure of a communication sent to Vienna from Berlin outlining the German plans for annexing parts of Russia and France. Excerpts from this official document were read by Herr Hugo Haase, leader of the Independent Socialists, before the committee of the Reichstag. France was to lose Briey and a strip of territory west from Luxembourg covering the iron deposits. These iron deposits and the Valenciennes coalfield constitute the industrial backbone of France; yet the Germans talk about a war of defence! No, it is a war by them for the despoiling of their neighbors and such domination as they can win by aid of that "good German sword" which does not scruple to kill anything—man, woman, or child—that stands in the way.

WE are pleased to record the birth of a new mining paper, which has the distinction of being the first one to be published in a country that was a producer of copper, and tin, and gold even before there was a Roman Empire. We refer to Portugal, and to the 'Revista Mineira e Metalurgica,' edited by Senhor A. Xavier da Fonseca, at Viseu. The enterprise starts modestly as a neatly printed folio of four pages, with articles on platinum and wolfram, both of which are found on the river Douro, and with other discussion of value. It is a good beginning, and the periodical will doubtless prove useful. The editor announces that it will be an accepted organ for the early publication of the discussion at the meetings of the Portuguese Miners' Association and of the Society of Civil Engineers. He also promises correspondence from mining centres in Brazil and Africa.

GREAT BRITAIN has increased her national debt from 708 to 5525 million pounds since the War began. These sums seem overpowering until one recalls the fact that her annual income is 2200 millions and her total wealth, before the War, 15,000 millions of pounds—not dollars. To lose a couple of year's income is unpleasant but not crushing to a man of vigor and resources. To lose a third of one's wealth is depressing, but not

fatal, provided the power of recuperation persists. The British people are bearing a daily expenditure, on the War, of \$32,000,000. They have raised £4,200,000,000 since the War began and they have loaned £1,100,000,000 to their allies. The larger unit of the pound sterling serves better than the dollar when talking in sums that are almost astronomical in their magnitude. By taxation alone a sum of money has been raised more than double the revenue of the country before the War. They have spared nothing. The United States has already increased her national debt from 1040 to 3105 million dollars. The income of the United States is ten times its debt and its total wealth, \$187,500,000,000, is such as to justify the lavish expenditure now being incurred to save our country from the gravest peril that has ever menaced it. All of this wealth would count but little in our defence if we had not the national character to use it efficiently and effectively for the great purpose in hand—to prevent the domination of the world by a military caste having no sense of honor.

MANGANESE constitutes a vital factor in the basic industry of steel-production. A keen realization of this has come to our people as a result of the exigencies of war. Many important foreign sources of supply were immediately closed, and such as were accessible to us and to our Allies soon proved nearly unavailable on account of the lack of adequate shipping to bring the ore from Brazil and Cuba. So long had we depended upon the stability of commercial relations with other countries that no serious effort had been made to secure an internal balance of our domestic resources. In this instance, as in so many others, we had neglected to prepare for the emergency of isolation. We publish in this issue a contribution on the possibilities of manganese production in California by Mr. George D. Louderback. His official position as chairman of the committee on geology and mineral resources of the California State Council of Defense, and his high standing as a geologist, give special value to his statement. He shows that the outlook for increased production is favorable, and he calls attention to the important studies being made in the concentration of low-grade manganese ores by Mr. E. A. Hersam in the University of California, and by the U. S. Bureau of Mines, as a result of which we may hope for the continuance of manganese mining after the War. The object of continuity should not be overlooked in the efforts made, under the impulse of extraordinary need, to utilize the resources that a bountiful providence has placed at our command. A wise nation is one that prepares for every contingency, and foresight directed toward economic independence is one of the essentials for protection against international difficulties. Professor Louderback also outlines a plan for encouraging the development of small manganese mines by association for purposes of assembling, grading, and shipping ores. We have urged also the organization of small producers of other ores, as a means for assisting the sale of their output. Much of the complaint against unfair treatment by the smelters is the

result of faulty sampling by the shipper, to which must be added the inability of the smelting companies to quote as favorable terms to small producers as are freely offered to those that can ensure a steady supply of ore of known grade and composition. An association of small copper miners, for example, producing from a district accessible to a common shipping-point, might readily accumulate ores in such quantity as to make them, acting as a collective shipper, important enough to command respectful consideration and to secure advantageous contracts for the disposal of their products.

Every Ounce of Our Strength

Despite the fact that this Nation is committed to the decisive arbitrament of a fateful war, it is evident that many of our citizens still fail to realize how momentous is the crisis. A friend of ours, a mining engineer of wide experience, commenting upon the recent meeting of the American Institute of Mining Engineers at New York, wrote that the proceedings "brought a realization of the fact that if the country put forth a *fraction* of its potential abilities and energy the cumulative influence on the War and on subsequent civilization will be irresistible." The italics are ours. The man that wrote this could not have meant what he said, for he is one that knows better, but apparently he echoed the talk around him—talk of a damnably pernicious character. As far as one can see, if this country should put forth only "a *fraction*" of its strength at this critical hour on this day of "unspeakable agony of the nations," it will fail in its purpose and have to face, if not defeat and invasion, a state of things that means an end to peaceful democracy, to national safety, and to the progress of the only kind of civilization under which free men care to live. The story is told that a negro condemned to death for crime was standing under the gallows when the sheriff informed him that it was his legal right to make a statement. "Have you anything to say?" asked the sheriff. "Yes, sir; I want to say that this am suttently goin' to be a lesson to me." Uncle Sam must not wait for such a lesson. Is this country to realize, only when it is too late, the sad consequence of half-hearted effort, or shall the whole people as a unit put forth every ounce of strength so that in the hour of judgment, inevitable when the tumult and the shouting dies, we shall stand safe and self-respecting? We want to be both safe and self-respecting if we are to continue to be a leader among the nations, if we are to keep alive the soul of representative government, if our hearths and homes are to be inviolate from the ruthless tread of a military domination that is without conscience and without shame. Most of our readers recognize these facts, but that is not enough, they must make it their business to instruct the less informed. The War cannot be won by the minority of educated people. Our profession is answering the call for personal service at the front, but there remains much to be done by those unfit for the one service that transcends all others in value and effective-

ness; we who remain at home can help by teaching those around us that this is a business to which each and every citizen stands committed. For example, the Garfield order for saving fuel was given a national interpretation, the resentment against personal discomfort showed how little most people appreciated the relation of the order to American help overseas, that is, to the success of the military campaign upon which everything is staked. We are continually diverted from intensive effort by announcements of sudden discoveries to defeat the submarine, by wild assertions concerning the squadrons of aeroplanes ready to end the War, by persistent yarns that the Enemy is in a bad way economically, and by irresponsible chatter from prominent men suggesting that the fighting is to end next month, next Christmas, or next spring. On the other hand, as a counter-irritant, equally pernicious, we hear exaggerated statements of an opposite nature: that the submarine menace is triumphant, that our munitions are terribly defective, and that the War will last twenty years. Then, as if to ridicule even the belated efforts we are now making, the 'Evening Howl' turns a patrol-skirmish into 'an American victory,' in big head-lines, and the 'Morning Scream' measures our accomplishment by the number of socks sent to the soldiers. Geographic separation from the scene of actual conflict and the lack of imagination characteristic of the uneducated, including many of academic standing, explains much of this profound ignorance concerning the vital issue. It is the business of every patriotic citizen to do his best to remove ignorance and to stimulate interest, so that we may go forward in unison to complete our task, which is to vindicate the law of nations and to bring the outlaw to account for his crimes, so that civilization may survive. One curious sidelight on current opinion is the interpretation of the British phrase 'to do your bit.' It is the English soldier's mock-modest way of saying that he is ready to lay down his life for his country and its cause; here in California it is taken literally as meaning that every member of the community must do a little, the cumulative effect of which is to suffice. This is another phase of the idea that if we put forth 'a fraction' of our energy we, being a great and resourceful country, shall turn the tide of war. So one man subscribes a dollar to the Red Cross, another foregoes pork on Saturdays, and a third pays 50 cents for a ticket to a concert for the French wounded, and then fools himself into the belief that he has done his 'bit'! How pitifully stupid! Public dining and public dancing continue with cynical contempt for the nation's travail, golf tournaments and symphony concerts are held as if the pterocyst of calamity were only a nightmare, tourists go their irresponsible way, politicians play politics, labor goes on strike, 'business as usual' is the motto of a large part of our population, as if the criminal folly of that sentiment had not been proved in England three years ago. The idea prevails that Uncle Sam is invincible, that he is sure to come out of this affair, as from others, with a victorious eagle

perching on his shoulder. We hope and believe it, but in the name of Washington and Lincoln, for the sake of all that makes life worth while, let us not stop at hoping and believing. Let us act! Our own deeds are our doomsmen.

Oil-Shale Legislation

Development of oil-shale is attracting well-deserved attention, after having been side-tracked as an American industry for nearly 80 years. The early efforts to distill oil from shale did not long survive the discovery of petroleum in the wilderness of western Pennsylvania. We are talking of the period when Millard Fillmore was President; when a Scotch boy named Andrew Carnegie had just arrived in this country from Dunfermline; before there were steel mills on the Monongahela and the Allegheny; when western Pennsylvania still was a region of unsubdued mountain and forest. At that time the distillation of shale available on the Atlantic Coast offered relief from the rising price of sperm-oil. Once again, after the market has been held so long by petroleum products, the growing cost of oil has turned the world's attention to the vast store of hydrocarbons that can be produced from bituminous or oil-bearing shale. The quantities at command from this source are measurable in billions of barrels; the evidence presented to the Public Lands Committee of the House of Representatives the other day showed possibilities so great that even 'billions' served as a small measure. Extensive areas in the United States contain shale from which more than a barrel of crude oil per ton may be distilled, and in addition enough ammonia may be recovered at many places to repay the cost of mining and treatment. It must be noted that the distilling of oil-shale is a technical process, requiring men of special training. It is not a safe business for the tyro. Nevertheless, it is an industry to which an army of young chemists and engineers will turn, with advantage to themselves and the world. The need for more and cheaper distillates to drive auto-trucks and aeroplanes alone is sufficient to induce the exploitation of oil-bearing shales. We publish in another column an interesting article on the oil-shale of Colorado by Mr. R. L. Chase. A rush has ensued to locate the more accessible outcrops in Colorado, Utah, Wyoming, Nevada, and California, and the question of obtaining unassailable title has become urgent. The Federal statutes make no specific provision in the premises. Presumably locations can be made under the placer law, and the Interior Department has so advised, but those interested in developing the new industry argue that the rules applying to placer claims do not fit the conditions of oil-shale mining. An association claim covers only 160 acres. This is small, and does not pre-suppose equipment for underground mining and ventilation. A plant for highly economical operation is so costly that a long life for the enterprise must be assured. A bill to cover the requirements is under consideration, and those interested in oil-shale distillation have represented to the Public Lands Committee in

Congress that a claim of 6000 acres is not excessive. To this the law-makers demur. We believe that the demand of the operators is fully justified. Although the aggregate resources of oil-bearing shale are large, it is evident that the margin of profit in exploiting them will not be great. The mining of the shale, especially where the thickness of the deposit is considerable, will present difficulties; distilling and refining plants are elaborate and expensive; from a financial point of view it will be a less attractive business than coal mining, and the equipment of a coal mine, for economical production, necessitates so large an outlay of capital that an area of 5000 acres is regarded as affording a minimum basis for a conservatively managed enterprise. It would be a misfortune to cripple a promising industry by obstructive legislation. Unwise action, in the name of conservation, resulted in the paralysis of potash development, in consequence of which we were unable to meet the demand for intensive fertilization of our farms at an hour of crisis. Similarly the phosphate deposits were tied up, so that we were unable to utilize the large possibilities of by-product sulphuric-acid manufacture in Utah and Montana that might have turned the Western phosphate-rock into fertilizer to supply the demand that today cannot adequately be met. Laws that interfere with the normal development of mineral resources restrict the growth and welfare of the Nation. The need for oil warrants the intensive development of the shale deposits to the limit of their capability; we hope therefore that Congress will take a broad and liberal view of its responsibility in this instance. Moreover, action should be taken promptly, so that initiative in this new industrial departure may not be intimidated by uncertainty regarding the treatment to be accorded by the Government.

A National Boycott

A few days ago the Chamber of Commerce of the United States of America, at the instance of the Boston Chamber of Commerce, submitted to its members a referendum, having for its burden the boycotting of German goods after the War unless the form of government in that country were radically changed. It is hard to understand why intelligent men should expend intellectual energy upon such a problem at such a time. Most people have become convinced that this war is not to be won by conducting a mere publicity campaign for democracy. An attempt to frighten the Germans into liberalizing their government by means of a threat of trade reprisal is unworthy of a body of representative Americans. It ought to be known to the leaders of industry, if not to the rank and file, that racial and national animosities do not operate persistently against the economic law that men invariably buy in the cheapest market. Sentiment will not constrain them to purchase the dearer article because it is made in a particular country. We may as well face the facts of human psychology. While our Government is struggling against the evil of profiteering, which is nothing more nor less than the exploitation of our own

people at a time when the best of them have dedicated themselves to the national cause, it is foolish to assume that business after the War will not be done on a strictly business basis. It is certain that discrimination against German goods will not be applied widely unless they cost more. If the Chamber of Commerce were to propose exclusion by a protective tariff, we would admit that it had a feasible plan. That it did not propose this is probably because President Wilson, on whose shoulders rest the grave responsibilities of national policy at a time of bitter stress, had pronounced in favor of free trade. That re-opens the long-debated question of protectionism, which came near to splitting Congress along party lines a few weeks ago when the President made his open-door declaration. It is more than probable, however, that unless the Germans meet a tariff-wall too high to be climbed, it will be impossible to exclude their goods by voluntary boycott. The mere proposal argues lack of serious thinking on the great problems before us. We must defeat Germany, or she will force her goods, her language, her customs, in short, her 'kultur' upon us. Germany is fighting for world dominance, and that means mastery. Her people believe that they are the standard-bearers of civilization; Hegel told them so, and he merely gave form to the idea that had long floated in the German mind. Every Teutonic philosopher and publicist since Hegel has reiterated it. Germany is now pushing into Asia Minor; she is converting the Balkans as fast as she can into an impregnable fortress to serve as a base for an onslaught upon Greece; she has declared the way free of obstructions to Persia, and with sorrow we must admit that so it is. We reflect upon the fine little army in Mesopotamia, with its line of communication depending, among other things, on keeping the Teutons out of Greece and Italy. There in the Levant is in progress the campaign that may settle the question for you and me as to the kind of cultus we may find it needful to adopt. There are bigger and better things to do at present than consume the time of business-men in discussing boycotts after the War as a means of checking the Prussian. If a boycott be in order, let it be proclaimed against the profiteer within our gates, against those that are doing so much to aid the Enemy, by checking and harrassing our own people in the work of the War. The Chamber of Commerce knows full well that a boycott against certain meat-packers and certain wool-merchants could not be made effective. That serves to illustrate the kind of trivialities on which they have been spending time while the country is calling for constructive thinking that can be carried into action to prevent the further success of German arms. Let us consider what we can do to keep the Mediterranean safe and to hold back the Teuton from the Pacific and the Indian oceans. Then we can turn to the West Front and break it in, after which the Germany that now threatens to absorb the world through the schemes of its new Imperial Ministry of Economics will no longer exist. We must plan, not for a feeble boycott, but for an association of nations strong enough to curb any outlaw.

Herbert Hoover, as Individual and Type

By VERNON KELLOGG

*The biographical details of Herbert Hoover's earlier years will not go far in explaining to us his present personality. Born in 1874 on an Iowa farm, of Quaker father and mother, he received through them that native endowment of potentialities which come, variously, to each of us by the process of heredity; processes still mysterious despite all the wealth of detail of mechanism and method which modern post-Mendelian study of heredity has revealed. We do know something of why a man's eyes are blue, if they are blue instead of brown, as another man's eyes are; and something of why he is mentally defective from birth, if he is, while another is so mentally sound.

But despite the cheerful confidence of those too optimistic specialists who say that the secret of inheritance is now known, and that, being given full knowledge of one's ancestors and collaterals to the number of several dozen, they will prophesy the physical and mental make-up of one's next child, the fact is that they cannot. They cannot, if for no other reason than that human births are too few per family to give them the advantage of the working of the Mendelian mathematical formulae on which their prophesying is based. Besides, they can rarely have that full knowledge of ancestry which they need. Mr. Hoover does not know, nor do I, the full history of his ancestry and collaterals, and the mere knowledge of the make-up of one's parents and of a few grand and great-grand-parents, is never sufficient to explain why anyone's inherited characteristics are just what they are.

The influence of one's environment is sometimes more nearly determinable. But there is one great difficulty about that, too, and that is, that to understand fully the effect of environmental influence requires a pretty good understanding of the native qualities of the material upon which the environment acts. The reaction of differently formed human beings is never exactly the same even when the environmental action on them is nearly identical. 'You can't,' as David Starr Jordan is wont to say, to explain some failures of college endeavor, 'put a thousand-dollar education into a fifty-dollar boy.'

Herbert Hoover's early environment was affected by the death of both parents while he was a child and his being handed over to the sympathetic care of various aunts and uncles, all of the Quaker faith and training. This condition must have placed in his own hands earlier than is usual with most of us, a certain personal share in the determination of his own environment. For example, when the time for his preparation for college came, he found himself on the Pacific Coast under the

care of a Quaker uncle, who had naturally planned that this preparation should lead him into a Quaker college. But already the youth had decided that his higher education should be obtained in a modern scientific university. This was a decision determined partly by the lack of control of the environment itself but more probably by the assertion of an inherited quality which made strongly for self-determination of behavior. He went, therefore, to Portland, and, supporting himself by his own exertions, was able in a couple of years to fit himself for his 'modern scientific university.' He entered Stanford University with the first opening of its doors in the fall of 1891, and thus entered on a characteristically pioneering career with Stanford's pioneer class of 1895. During his four years at the university he again supported himself by his own exertions.

Now, without doubt, these six years of earning his own way as a youth of fifteen to twenty-one years were an environmental influence which had its real effect, and one probably recognizable and of much importance today in its results. He learned early something enduring about values in human life; about things that count and things that are superficial. And he learned something of his own capacities, and to have confidence in them. One of his present outstanding characteristics is confidence, although a confidence never weakened by conceit.

His major work in the university was in the department of geology and mining, under the supervision of a sturdy, direct, natural teacher and investigator, John Casper Branner, a scholar of practical mind, intent on truth and essentials. This association was good environment for the rapidly developing young man, already inclined by native instinct and boy's experience to be intent on the same things.

Dr. Branner's advice to the students graduating from his department—to be miners for a while before being 'mining engineers'—was followed quite literally by Hoover, who went into a Sierran mining-camp and was there miner and shift-boss, and perhaps other things, before he turned again to mining engineering as helper in the office, in San Francisco, of Louis Janin, the best-known mining engineer in the West.

He was soon out of the office, however, and again in the mines of California, Oregon, Idaho, Wyoming, and Arizona, where he staid until he received an offer from an engineering firm to go to Western Australia. Here, in 1897, after only two years of mining engineering apprenticeship since graduation, he was an arrived and successful mining engineer in the position of manager of one of the most famous of Australian mines. There can be no doubt that native capacity was as largely responsible

*Abstracted from 'The Atlantic Monthly', March 1913.

for this swift achievement as good training and other environment.

In another year (1898) he was manager of two other great Australian mines, and in one year more he was director of mines for the Chinese Empire. This gave him a chance to go through some highly spiced adventures in Tientsin during the Boxer Rebellion of 1900.

Crossing with him from Thamesmouth to Flushing in the summer of 1915, on one of the small Dutch boats which were allowed by Germans and Allies to maintain a precarious cross-Channel connection between the Continent and England, I heard from him as we walked the narrow decks, with a constant eye out for casual floating mines or careless submarines, many stories of his experiences in Australia and China. I do not remember many of the incidents, but I remember clearly the general impression made on me by all of them together. It was, that the chief actor in them was a man of level head, clear vision, entire fearlessness, and great resourcefulness and directness of action.

Since then I have had the opportunity, given by close association, to see him think and act under circumstances of continuous serious importance. I would use the same words now to express my present actual knowledge of his qualities which I have just used to express my impression of them gained on the uneasy little Dutch boat.

After the Chinese experience he became a junior partner in a London mining firm, at that time (1902) perhaps the greatest in the world. During this partnership, which lasted until 1908, Hoover had the experience of meeting the task, largely because of his own attitude in the matter and through his own exertions, of making good to the firm's clients the defalcation by the firm's financial member of about a million dollars. In 1908 he had restored the sum, sold his interest in the firm, and was a man free and wholly competent to go it alone successfully in the world's arena of mining business. And ever since then he has gone it alone, and successfully.

It is beyond the province of this sketch to recite any of the details of his impressively successful handling of large mining affairs in Russia, Burma, Central America, Mexico, and elsewhere. He has been successful in making money for his associates and for himself out of many undertakings; but, more importantly, he has been successful in making good mines out of what in other men's hands had been bad ones. That, indeed, has been his special work in mining: not promoting mines and selling mining shares to an easy public, but making the earth yield its treasures even when it seemed most reluctant to release them. He has made his money in mining out of the ground, not out of the pockets of investors.

MAGNETITE ores are being smelted at Ipanema, in the State of São Paulo, Brazil, and another smelter has begun to produce pig-iron at Itabira do Campo, in Minas Gerais. On account of the availability of large quantities of water-power in the mountains along the Brazilian coast, an important development of electro-smelting in the near future is predicted by the Brazilian branch of the National City Bank.

Production of Magnesium

Four American firms produced all the magnesium in the United States in 1916 (75,400 lb. valued at \$311,570), while in 1917 five firms produced 115,800 lb., valued at \$233,600. Toward the end of 1917 the price was \$1.85 per pound. The statistics of production were collected by Frank L. Hess, of the U. S. Geological Survey. In 1916 magnesium was made by the Electric Reduction Co., Washington, Pennsylvania; Norton Laboratories (Inc.), Lockport, New York; Rumford Metal Co., Rumford, Maine; and General Electric Co., Schenectady, New York. The Electric Reduction Co. has found it more profitable to use its power for other purposes, but the other companies produced magnesium in 1917. The American Magnesium Corporation, the successor of the Aviation Materials Co. at Niagara Falls, made an output in 1917, and the Dow Chemical Co. began production at Midland, Michigan, but was prevented from operating at its full capacity by shortage of coal. The General Electric Co., which in 1915 had been forced to make magnesium in order that it might have the metal needed for its own work, closed its plant in 1917, as the industry is now well established in this country and the price has fallen to a point near that which prevailed before the War. The Rumford Metal Co. and the American Magnesium Corporation have investigated and produced alloys of magnesium with aluminum, calcium, copper, iron, nickel, and silicon.

DIATOMACEOUS EARTH is used chiefly for cleaning and polishing, either in the form of powder or mixed with soap. It is an effective non-conductor of heat and has been used alone or with other materials as a covering for boilers, steam pipes, and safes, and in fireproof cements. It is used largely by paint manufacturers as a wood filler. Boiled with shellac it is made into records for talking machines. It has been used for absorbing liquid manures so that they could be utilized as fertilizers, and as a source of silica in making water-glass, as well as in the manufacture of cement, tile-glazing, artificial stone, ultramarine, and other pigments of aniline and alizarine colors, paper-filling, sealing wax, fireworks, hard-rubber objects, matches, and papier-mache, and for solidifying bromine. Bulletin 483 of the U. S. Geological Survey, dealing with all the economic minerals near Richmond, Virginia, gives valuable details regarding diatomaceous earth.

GYPSUM is added as flux to galena concentrate in the Carmichael-Bradford blast-roasting process of reducing lead ore, a process patented in the United States in 1902, but used only at a smelter in New South Wales. Gypsum is used as flux in the concentration of lead-copper matte in reverberatory furnaces in Germany. In the smelting of some grades of nickel ore in New Caledonia, gypsum is employed to furnish the sulphur needed for collecting the metal in a matte. The lime of the gypsum then acts as a base to slag the silicious gangue.

found chiefly, though not entirely, in the fact that the great population of the East leads to a demand for the by-product that can be made from the fume. A like condition is developing in the West. Diversification of industry is encouraging a more insistent call for sulphuric acid, and the high cost of transporting it makes local manufacture imperative. The response is relatively easy, since the tendency to reverberatory smelting has been accentuated by continued improvements in this process, and by the increasing output of flotation concentrate, which cannot be smelted in the blast-furnace. The roasting of ore and concentrate, which is a necessary preliminary to reverberatory smelting, yields fume rich in sulphur di-oxide, and this is available for the making of acid. Moreover, one Western acid-plant, at least, has been erected partly for the purpose of supplying acid to the farmers, since it has been found that alkali lands can be reclaimed for profitable cultivation more effectively and cheaply by the direct application of this substance than by any other means. The American Smelting & Refining Co. anticipates a large demand for this use, which it is preparing to meet from its acid-annex at the Garfield smelter in Utah. At the same time the application of sulphuric acid for leaching low-grade copper ores is growing rapidly, so that smelter-fume is coming to represent an asset instead of being a nuisance and a cause of legal strife. The new development of acid-manufacture is in response to a demand from both farmer and miner. The first acid-plant in the West, in conjunction with copper smelting, was erected as an escape from the persecution of the farmer. This was at the Mountain Copper works on San Francisco bay, this plant being designed by Lewis T. Wright, who thus became the pioneer acid-making copper metallurgist in the western United States.

It will be recalled that when the Copper Queen officials selected the site for a smelter at Douglas, in the Sulphur Springs valley, Arizona, the absence of favorable conditions for agriculture was noted with considerable satisfaction. The elevation, combined with the extreme dryness of the atmosphere, resulted in such a wide variation in the temperature between day and night as to limit the possibilities of successful farming; but the pall of smoke that spread over the valley from the smelters reduced the radiation of heat at night so that these conditions were changed, and ranchers began to crowd around the new market established by this metallurgical industry in what before had been an almost unpeopled desert. Next followed threats of litigation because of damage to crops from the sulphurous smoke. The smelters, however, pointed out that all they needed to do was to close the works for a period to re-establish the former climatic conditions; the farmers then literally would be frozen out. Accordingly wisdom and peace prevailed together. Nevertheless, Douglas now has an acid-plant, called into being by the needs of the leaching-works at Ajo. When it became apparent that a great body of copper-carbonate ore existed at Ajo, and that it must be treated with sulphuric acid, two possible solu-

tions of the problem had to be considered. One was to ship pyritic ore from the Bisbee mines and manufacture acid at the point where it was to be used; the other was to roast the ore at the Douglas smelter of the Calumet & Arizona Mining Co. and produce the acid there for shipment to Ajo. Estimates showed that it was cheaper to produce the acid at Douglas. It was a question of balancing the cost of transporting the acid 295 miles over three railroads, or of taking copper-bearing pyrite to Ajo, and returning the calcine for smelting. Leaching of the calcine would have involved a separate process, different from that which had proved adaptable to the New Cornelia ore, and the ferruginous calcine-tailing would have been useless. At Douglas the iron in the calcine admits of smelting an additional quantity of silicious ore. Accordingly an acid-plant became an adjunct of the C. & A. smelter, and was the first one to be built in the State of Arizona. The output is 210 tons of 60° B. acid daily, 75% of this being consumed in copper-leaching at Ajo.

Sulphuric acid in the chemical industry is a fundamental necessary. In outline the method has settled down nearly to a matter of routine, yet no branch of manufacture remains stationary. When it ceases to progress it is obsolescent. Acid-making actually is changing materially in America; in many matters of detail the world's great authoritative work on the subject, by Georg Lunge, is now out of date. The dingy, dirty, corroded wooden structures, with their encrusted and leaky lead-chambers suspended in lead pans, which one may see scattered plentifully throughout the East, and which hark back to the days, not so long ago, when the acid-makers of England and America questioned the fairness of granting a gold medal to John Glover for his famous tower, look like models of medieval crudeness beside such splendid examples of efficient engineering as may be seen, for instance, at the plant of the Davison Chemical Co. of Baltimore, where everything is built of steel and tile, with magnificent chambers burned and raised wall by wall without the distortion of lead sheets seen in the older works; where durability, neatness, accessibility of parts, perfection of detail, all unite in producing economy. It is to pay a deserved compliment that the plant of the C. & A. is compared with so noteworthy an example of modern methods; indeed, there are some details at Douglas that might serve as useful models to the able managers of the Davison Chemical Company.

Despite the fact that every chemist learns the principles of making sulphuric acid in his primary lecture-course, the complication of Western metallurgic establishments by sulphuric-acid annexes is sufficiently novel to make a brief outline of the process of use to some who may thereby be encouraged to utilize their own by-products. The object is to change the fixed gas, SO_2 , into the hydrated trioxide, $\text{SO}_3 \cdot \text{H}_2\text{O}$, that is, the H_2SO_4 of commerce. In other words, it means the further oxidation of SO_2 , which, in the chamber process, is accomplished in connection with nitrous oxides and water-

BATTERY OF HEGELER ROASTING-FURNACES, C. & A. ACID-PLANT, DURING CONSTRUCTION

PART OF COLUMN, WITH RABBLE-ARMS, HEGELER ROASTER

NITRE-POTS IN NITRE-HOUSE

INTERIOR OF LEAD-CHAMBER

vapor. These are the fundamentals of the process. There is, furthermore, an important addition to the total yield through the action of nitrous vitriol in the Glover tower, making a stronger acid, partly by concentration of the chamber acid fed through the tower, by reason of the heat of the incoming roaster gas, and partly through the reaction, as given by Lunge:

The accompanying straight-line flow-sheet, representing the plant erected at Douglas, will enable the method to be followed more easily. The pyritic ore is roasted in the same type of hearth-calcliner as that used for desulphurizing copper-sulphide concentrate preliminary to reverberatory smelting. In this plant the Herreshoff furnace is used, built by the Pacific Foundry Co. of San Francisco. The gas, containing 6 to 7% SO_2 by volume, is passed through a dust-chamber for initial cleaning. It may be stated that acid-makers aim at as high a volume-percentage of SO_2 as possible, since it enables the work to be done with smaller and fewer chambers, and, if conditions permit, a content of 7.5% average would be preferred. At Douglas, however, the roasting is done with consideration for the highest combined efficiency of both the acid and the smelting plants, limited by the available economic ore-mixtures. The nitrous oxide is introduced by the nitre-pot system, in accordance with prevalent American and English practice, instead of by nitric acid, as is more commonly done in Europe. Accordingly the hot gases leaving the dust-chamber are led by a flue to a double-compartment chamber having 12 'nitre-pots,' shaped somewhat like a bath-tub and made of cast-iron. These are charged with Chilean nitrate of soda, sulphuric acid is added, and, under the action of the heated gases, which pass over and beneath the pots, the nitric-acid vapor is evolved and mixes with the sulphurous gas. The contents of the pots become liquid, and when the reaction is complete this liquid is discharged outside the chamber, where it solidifies into what is known as nitre-cake, this is, acid sodium sulphate, NaHSO_4 . No attempt is made at the Douglas plant at this time to convert it into salt-cake, Na_2SO_4 , nor is it used, as at places where the demand justifies such a step, for making hydrochloric acid by heating it with common salt, or roasting with coal in a reverberatory type of furnace to form sodium sulphide. It here constitutes a waste product, and it accumulates at the rate of 2 tons per diem. The gas enters the nitrating-chamber at a temperature of 800° to 900° F., and thence passes to the Glover tower, which is filled with a checker-work of Duro chemical tile, where it meets descending films of sulphuric acid mixed with nitrous vitriol. The ensuing reaction utilizes the nitrous oxides in these liquors by combining with some of the SO_2 in the gas. At the same time the stream of gas is cooled to about 210° F., and the resultant evaporation helps to concentrate the acid which, at the Douglas plant, is drawn from the towers at a strength of 60° B. This is the finished acid as shipped to Ajo. Only a part of it, however, is diverted to the storage-tanks: the greater portion is necessarily returned to the Gay Lussac towers, where it recovers the nitrous oxides that issue with the waste-gas from the last lead chamber in the series. It then circulates, as nitrous vitriol, once more through the Glover tower, thus maintaining a cycle. The gas emerging from the top of the tower goes through a series of five tall cylindrical

cooling-chambers, made of lead, and permitting radiation of heat through the walls. These bring the temperature down to 190° F. A large lead fan exhausts the gas from the cooling-towers and forces it into the first lead chamber, where the reaction that results in forming sulphuric acid takes place. There are six lead chambers, with three cooling-towers between each pair, with the exception of chambers No. 3 and 4. In many plants steam is introduced into the chambers, but the reactions being exothermic, and a reduction of the temperature being necessary to facilitate good work, 'atomized' water is preferable and is here used in accordance with the best American practice. The water is atomized by the Schutte & Koerting Co.'s type of platinum-pointed spray-tip, just inside the roofs of the chambers. The chamber-acid produced is approximately 53° Baumé. This is maintained at a constant level within the chambers, the excess siphoning off and joining the cycle through the Gay Lussac and Glover towers. From the last of the six chambers the gases issue at a temperature of 140° F.; thence they are drawn through a series of six cooling-towers by a lead fan that also drives them through the Gay Lussac towers, which are similar to the Glover, except as regards their size and details of construction. The waste-gases now containing the nitrous oxides and about 0.10% of SO_2 , meet the sulphuric acid trickling down over the Duro tile, and the nitrous oxides are absorbed, forming the nitrous vitriol ready to re-enter the Glover tower.

From the general view of the plant, it will be seen that the Gay Lussac and the Glover towers, the 'nitre-house,' the cooling-tanks, the dust-chamber, and the roasting-furnaces, are concentrated at one end, that is to say, the gases, after traveling ahead through three lead chambers, double back through another parallel series of three more chambers to the Gay Lussac towers. This facilitates technical control as well as convenience in operation, and is a plan common to all modern plants. The Calumet & Arizona plant was designed by the Process Engineering Co. of Philadelphia, the actual construction being done by the engineering and mechanical departments of the Calumet & Arizona, aided by C. S. Rogers, construction engineer of the Process Engineering Co., in conjunction with A. C. McGregor, mechanical engineer of the Calumet & Arizona company. At present K. B. Thomas is the superintendent of the plant.

Roasting is done in a battery of 24 Herreshoff furnaces, each having six hearths, $21\frac{1}{2}$ ft. inside diameter, lined with 9-in. firebrick, contained in a shell of $\frac{3}{4}$ -in. steel-riveted sheets. The hot air from the cooling-column passes downward through a series of rectangular bustle-pipes, 6 by 12 in., spaced 2-ft. centres, built into the brick wall. This serves to economize the heat that would otherwise be lost, and to maintain a proper working-temperature on the hearths. The speed of the plow-arm is one revolution per minute, and each furnace requires $7\frac{1}{2}$ hp. Of the entire battery of furnaces, 19 are used for roasting an excess of ore beyond what is needed to

supply SO_2 for acid-manufacture, and the sulphurous gas from these is discharged into the air through a stack. They are referred to as 'open' furnaces. The remaining five are 'closed' furnaces, that is, the gases go to the acid-

plant. There is a great difference in the speed of desulphurization in the two groups, the open furnaces treating each from 90 to 125 tons of ore daily, while a closed furnace burns only about 70 tons. The average

OUTLINE SKETCH OF GLOVER TOWER

ACID-COOLER

CHECK-VALVES FOR BLOW-CASES

sulphur content of the feed is 30%, and the calcine contains about 10%. A typical analysis of the ore is as follows:

	%
Silica	20.1
Alumina	3.2
Iron	29.2
Lime	1.7
Sulphur	29.2
Copper	5.12

The copper content is raised in the calcine to 6.6% as a result of roasting. The temperature is at a maximum on the third hearth, where it is 1400° F. If the higher heat invades the second hearth the elimination of sulphur is poor. On the sixth hearth the temperature is 800° to 1000° F. The air used for cooling the arms and the central 5-ft. column enters the down-take bustle-pipes at a temperature of 450° Fahrenheit.

For the roasting-furnaces supplying the acid-plant there is a separate concrete dust-chamber, 23 ft. 6 in. by 20 ft. in horizontal section, and 28 ft. high, insulated with 'sil-o-cel' brick, filled with a checker-work of hollow tile, 4 by 4 by 8 in., made of hard-burned fireclay. These are set so as to discharge the dust downward. The amount of dust drawn daily is between two and three tons, the gas carrying about 1.5% of the ore fed. Once each month the chambers are blown out with compressed air. The nitre-pots are shown in the accompanying illustration. The size of each pot is 4 by 2 ft., and the chamber is 33 by 12 ft. by 19 ft. 7 in., built of concrete and lined with Duro acid-proof brick laid in Duro cement. A charge of sodium nitrate is shoveled in through the work-doors, and sulphuric acid is introduced. The amount of nitrate of soda charged varies with the entrance-gas and the condition of the chambers at the time, while the amount of sulphuric acid charged varies with the nitre charge. The reaction is complete in two hours and the liquid acid sodium sulphate is tapped out into cast-iron cooling-pans. The nitre consumed is calculated on the basis of the sulphur in the acid made, not on the amount of sulphur burned. This corresponds to $2\frac{1}{2}$ % of the sulphur content of the acid. The nitre contains 96% NaNO_3 , and costs about 3½c. per pound.

The gas, now at a temperature approximately 20° lower than the gas entering the nitre-house, is delivered to the Glover tower through a lead flue 11 by 15 ft. This tower is octagonal, 22 ft. 2 in. diam. by 56 ft. high. It has a steel frame, holding the walls, which are built of Duro brick laid in Duro cement, containing about 96% silica mixed with sodium silicate as a binder. The tower is packed with Duro tile, $1\frac{1}{2}$ by 6 by 12 in., laid in checker formation as shown in the illustration, which is a view taken above the packing. The tiles are so laid as to be self-supporting; thus they exert no thrust upon the walls such as must be resisted when quartz packing is employed. This acid-resistant 'chemical tile' is made by the Harbison-Walker Refractories Company.

After the gas has lost some heat and has parted with a portion of its SO_2 in the Glover tower, it is conducted

through a 6 by 10-ft. lead flue to the first series of cooling-towers, each of which is made of lead sustained by a steel frame, and is 41 ft. high by $17\frac{1}{2}$ ft. diam. The gas enters at the bottom and leaves near the top, both inflow and outflow pipes being connected tangentially so as to induce a spiral motion. The gases are thus driven toward the periphery, facilitating the radiation of heat through the lead wall. The motive-power for drawing the gases from the Glover tower and through the cooling-towers is supplied by a lead fan, 4 ft. wide and 8 ft. diam., with a speed adjustable within the limits of 150 to 200 r.p.m., and moving a volume of 60,000 to 70,000 cu. ft. of gas per minute. The use of the cooling-towers increases the reaction, thus economizing the nitrous oxide, and yet holding the temperature lower. The fan delivers the gases into the first acid-chamber, which is $143\frac{1}{2}$ ft. long, 59 ft. wide, and 41 ft. high. There are six similar chambers, with cooling-towers between, as previously explained. The accompanying view of the interior of a chamber, taken during construction, shows the bottom sheets of lead, which weigh 8 lb. per square foot, and also the edges that have been burned together. Likewise the seams of the vertical sheets stand out clearly. The side-walls consist of 6-lb. sheets of lead. Six sheets, making five seams, are burned with the sheets lying flat. This makes a better seam. The section is then raised into position, and the laps between successive sections are burned together. The top is also of 6-lb. lead, burned flat on temporary staging. There is no acid-pan, but the bottom 8-lb. sheets are turned up and burned solid with the side-wall sheets. The chamber rests on a slatted floor to admit of better radiation, and the top is hung from the steel framework, as seen in an accompanying illustration. A detail drawing shows the method of attachment. Lead straps are burned upon the 6-lb. top sheets, and turned to form an eye to receive a $\frac{1}{2}$ -in. iron bar on the end of a threaded hanger with a special nut or washer resting on a pair of adjacent angle-bars.

The total space in the six chambers and the 23 cooling-towers combined is 2,155,000 cu. ft., affording a little more than 12 sq. ft. of radiation surface to every 100 cu. ft. of capacity. For the addition of the water necessary for effecting the acid-forming reactions the Schutte & Koerting platinum-tipped jets are used. These disperse the water in the form of a fine mist. The first chamber is provided with 12 jets, spraying $2\frac{1}{2}$ gal. each per hour. The second chamber has 24 jets, the third chamber 28, and the fourth 24, each spraying 5 gal. of water per hour; the fifth chamber has 20 and the sixth 12 jets, each delivering $2\frac{1}{2}$ gal. of water per hour. The intermediate cooling-towers also have one jet each, spraying $2\frac{1}{2}$ gal. per hour.

A second lead fan, of the same dimensions, namely, 4 by 8 ft., placed at the end of the system of chambers and cooling-towers, forces the gas into the Gay Lussac towers. These present a radical departure from the usual construction. Twelve towers are built into a solid

METHOD OF HANGING TOP OF LEAD CHAMBER

METHOD OF SUPPORTING CHAMBER-TOP

block, each tower being 13 ft. square by 45 ft. high. They are built of Duro brick, laid in Duro cement, and the interior is packed with Duro tile in the same manner as the Glover tower. It has been the general custom to pack Gay Lussac towers with hard-burned coke. The pores of the coke fill with acid, so that only the exterior of the pieces remain effective in presenting the films of acid to the gases, but it has been thought that the roughness of the surface extended the film of liquid and produced superior results. The Duro tile, however, as em-

Details of Return Bend

MULTIPLE-STAGE PÖHLE AIR-LIFT FOR PUMPING ACID

ployed in the plant of the Calumet & Arizona, has yielded as good an effect, and the packing is indestructible. The cold acid pumped from the Glover tower issues from the bottom of the fourth Gay Lussac with a nitrosity equal to $1\frac{1}{2}$ oz. NaNO_3 per cubic foot of acid; from the second with an equivalent of 10 oz.; and from the first with a nitrosity of 35 to 40 oz. The entire block of Gay Lussac towers is enclosed in lead sheeting, hung upon a steel frame. The towers are so arranged that the gas coming from the chambers is divided into three parts, each part passing independently through a series of four towers. At the base of each of the last three the discharged acid is cooled in acid-coolers before being pumped to the next tower in the series. Large steel blow-cases are used for the circulation of the tower-acid, each blow-case having a capacity of 20 tons of 60° B. acid. This pumping system is in duplicate to avoid delay when repairs are needed.

The acid from the chambers is elevated 90 ft. to the Glover tower by an ingenious adaptation of the Pohle air-lift. This is shown in detail in the accompanying illustration. The acid is lifted in stages, through lead pipes, the distance between successive receivers being 15 ft., while the total lift in each column is 45 ft. The compressed air is introduced by a jet, as shown in the detail drawing, just above the bend of the pipe. The acid flows by gravity from the receiver, and the air lifts it to the next receiver above, and so on to the top. The adjustment of the air-pressure is accomplished by a Davis regulating valve. This simple device has a pumping capacity of 300 to 500 tons of acid per diem.

The cooling-tanks are built with steel frames, inside of which is a 6-lb. lead sheeting, lined with 4 in. of Duro brick laid in Duro cement. They are 16 by 9 by 5 ft., and each tank contains 5000 ft. of lead pipe, $1\frac{1}{2}$ in. diam., with $\frac{1}{2}$ -in. walls. Instead of being in large coils, the lead pipe is in coils 15 inches in diameter like coil-springs. They are then placed in the tanks with the central axis in a vertical position. Each coil is independent of its neighbors and is easily replaceable. The total length of coil for a given capacity of tank is increased 40% over the old system by this arrangement.

It is a matter of peculiar interest to find Arizona among the sulphuric-acid producing States of the Union. The cause for such an enterprise here has been the requirement for leaching copper ore, and the plant was built primarily to meet this necessity. Nevertheless, it has already responded to a wider demand, so that a fourth of the output is shipped to other points than Ajo. The success attending the leaching operations in the plant of the New Cornelia Copper Co. will promote the application of the process to ores in other localities, and this will extend the market for acid. Furthermore, the general consumption in the arts is certain to increase throughout the West as a result of the intense stimulus given to manufacturing by the extraordinary conditions that the War has created. A country once awakened to its opportunity for producing the articles of common need will not lapse into inaction after the initial impulse

has been withdrawn; the freight differential alone will serve to maintain a protective margin of profit sufficient to ensure the continued growth of industry once established. Since sulphuric acid is recognized as a criterion of industrial development, it is evident that a large demand for this chemical henceforth will encourage the utilization of the waste smelter-fume in the Western States. The Western farmer is beginning also to appreciate the need of super-phosphate, to which he has been relatively indifferent in the past. This will call for the mining of phosphate rock from the great deposits that stretch from Wyoming and Utah into Montana and Idaho. It is by no means improbable that the smelters in Utah and Montana soon may find it profitable to ship fertilizers to the agricultural districts of the Mississippi valley, by reason of their command of a cheap source of acid-making material in close relation to large deposits of raw phosphate. It is certain that the manufacture of sulphuric acid will soon become a notable feature at many of the copper smelters throughout the West.

BRAZIL has made its first steel. This was accomplished in the Engenho de Dentro works of the Central Railroad of Brazil, about 10 miles from Rio de Janeiro, on October 19, 1917. Up to this time all attempts to manufacture steel from native pig-iron apparently had not been commercially successful. The railroad used a Whiting converter, purchased in the United States, and though the steel was for its own use in locomotive-parts, the success of the undertaking is looked upon as demonstrating the commercial possibilities of the process. The Central Railroad foundry constitutes part of its locomotive repair shops. As a portion of its equipment two No. 3 $\frac{1}{2}$ cupolas, purchased from the Whiting Foundry Equipment Co., were erected in 1914, having a rated capacity of five to six tons per hour. For some years it has been making gray-iron castings ranging in size to 3000 lb. Native pig-iron, with a mixture of about 40% scrap-iron, but without steel-scrap, was used.

A RECENT method proposed for fixing nitrogen from the air, as described by L. L. Summers, consists in mixing manganese di-oxide with powdered coal or coke, this being placed in an annular reaction-zone of an electric furnace. When the charge has become bright red, pre-heated air is introduced through tuyeres, the temperature of the mass being maintained at about 1000° or more. Carbides of manganese are formed, which fuse and then decompose at the higher temperatures, and volatilized compounds of manganese, nitrogen, and carbon are formed, which issue from the closed furnace to a condenser where the nitrides are decomposed to obtain ammonia. Cyanogen compounds and oxides of nitrogen are also produced. Coal may be substituted for coke, and producer-gas for air, in which case derivatives of cyanogen are obtained. It is suggested that the same apparatus may be used in the manufacture of manganese carbide suitable for producing CH_4 for gas-enrichment.

The Oil-Shale of Colorado

By R. L. CHASE

A new industry for the United States is starting in north-western Colorado and bids fair to assume tremendous proportions in the near future. This industry is oil mining, and consists of the mining of oil-shales, and their destructive distillation with the production of oil and other by-products.

On the accompanying map I have shown the area of oil-shale in Moffat, Rio Blanco, and Garfield counties, covering 2500 square miles. The oil-shale occurs in the upper part of the Tertiary rocks, in what is known as the Green River formation. This formation reaches a maximum thickness of 2500 ft. and consists essentially of shales with narrow beds of sandstone interbedded. The upper and lower parts of this formation are relatively barren, the middle portion forming the commercial beds of oil-shale.

The shales lie practically horizontal; at one time they formed a plateau about 9000 ft. above sea-level. Since then erosion has been active, and the plateau has been cut by streams leaving mesas that tower in some instances 1000 ft. above the valleys. It is the mesas and hills that contain the oil-shale, usually as a cap, because the oil in the shale cements it and makes it resistant to weathering. A rich stratum of shale is thus easily distinguished from the poorer, as it forms projecting combs along the outcrop. The rich and poor strata are interbedded, so that a rich stratum may alternate with a poor one. The workable beds are those that can show a rich section of at least three feet.

The shale is light in color at the outcrop, the poorer varieties being nearly white, whereas the portion that yields the most oil has a grayish tint. This gray shale, however, shows a dark-brown to black color on a freshly broken surface and appears massive. Upon being burned it breaks down and shows the shale-structure clearly. This weathering extends only a few inches to possibly a foot from the outcrop, so it is easy to get to a fresh surface for sampling. The oil occurs in the shale as a mass of plant and animal remains plainly discernible with the microscope. When the shale is heated the oil is driven from these organic remains, as all organic matter carries some oil. If these beds of shale had been covered by later formations and been

subjected to heat and pressure the oil would have collected and we would have had an oilfield.

The oil content of the richer portion of these shales

varies from 10 to 90 gal. per ton, making a bed of commercial thickness that will produce 40 gal. per ton not uncommon. The most valuable by-product is ammonium sulphate, many beds of shale yielding 17 lb. per ton.

It is said that shale carrying 1% nitrogen will yield 65 lb. of ammonium sulphate per ton.

The distillation of oil-shale is by no means a new thing, for it has been carried on successfully for many years in Scotland, France, and other countries on shales not as rich as these of Colorado. In Scotland the shale beds have a dip of about 35°, making mining difficult, while the average yield per ton of shale has been estimated at 25 gal. The cost of mining has been \$1 per ton, 40c. per ton for distillation and 46c. per ton being the cost of producing ammonium sulphate from a ton of shale.

In Colorado many shales produce 40 gal., or one barrel per ton, as there are 42 gal. to the barrel. The cost of mining on a large scale would be low, as the strata lie horizontally, and in some places it would be possible to strip the deposit and mine with steam-shovels. Probably a 75c. to \$1 mining cost would be realized. The cost of distillation and the cost of producing ammonium sulphate would be higher than in Scotland, owing to the higher cost of labor and material. This might be offset by improvements in the plant. Ammonium sulphate is worth at the present time 7c. per pound and is therefore a valuable by-product. The industry in Scotland has paid handsome profits while working much lower-grade shale situated less favorably. The value of the product has been less also, as the price paid for ammonium sulphate was formerly 3c. per pound and other things low in proportion. To offset these advantages in Colorado are the high cost of materials, high wages, and the competition of large oilfields.

If handled on a large scale the distillation of the better portions of these oil-shales should prove profitable. Several companies are now waiting for spring to build their plants and prove how profitable it may be. In some ways the enterprise is comparable to the development of the 'porphyry' coppers, where everything depended on a large production at a low cost. That is the essential feature in this case and makes necessary a large investment in plant.

OVER a year ago a leading automobile engineer said, at the annual meeting of the American Chemical Society, that he preferred electric to crucible steel in the special alloys that they used. A prominent English authority recently declared: "There is no carbon steel or alloy steel and no kind of casting, whether heavy or small, that cannot be made better and more profitably in an electric furnace than by older methods." The best quality of steel was formerly made in crucibles and called crucible steel. Electric furnaces are much larger than crucibles, those of 25 tons or more being now in general use. The heat of the electric arc melts and boils the iron and refines it into steel. It is really the wholesale way of making high-grade steel against the retail way in the old crucible process. The number of electric furnaces, operating or contracted for in the United States on January 1, 1918, was 233, as compared with 136 a year ago, and with only 73 on January 1, 1916. Three years ago, on

January 1, 1915, there were only 41 such furnaces. In the world on January 1, 1918, there are estimated to have been 733 electric furnaces in the steel industry, as compared with 471 on January 1, 1917, also a large expansion. With Canada credited with 36 furnaces, the total outside of the United States and Canada, on January 1, was 464 against 316 a year ago. England ranks second, with 131 furnaces, and Sheffield has 70 furnaces within its boundary, or more than any other city in the world. The world's output of electric steel is probably not far from 4,000,000 tons per year, of which the United States and Canada turn out about 45%, or 1,800,000 tons. On July 1, 1913, the electric steel industry of the United States was insignificant and Germany led the world, with 19 furnaces in the United States and 34 in Germany. At the beginning of 1918, 4½ years later, the industry in the United States had expanded over 12 fold.

Gold on Creeks in Copper River Basin

Alaska continues to be a good paying investment for Uncle Sam, its mineral output in 1917 having been more than \$41,000,000, and although the production of gold was somewhat reduced the interest in the gold placers is still keen. Among the rich placer deposits are those of Valdez creek, which have yielded gold valued at \$375,000.

Gold has been found in its bedrock source in the slate area south of Valdez creek and is present in some of the stream-gravel deposits within that area. Most of the placer gold from this district, however, has come from an old gravel-filled channel, formerly occupied by Valdez creek, and from the stream gravels of that part of the present channel which lies below the point where the old and new channels intersect. The gold in the new channel is largely a re-concentration from the auriferous filling of the old canyon.

Slate creek, 75 miles east of Valdez creek, is the site of an older camp. Miller gulch has been the greatest producer of placer gold within the Copper River basin, having yielded more than one and three-quarter million dollars. The U. S. Geological Survey has on hand a few copies of Bulletin 498, 'Headwater Regions of Gulkana and Susitna Rivers, Alaska,' by Fred H. Moffit, a report which deals primarily with the district including the Valdez creek gold-placers, and also gives an account of mining developments in the Slate Creek district, at the head of Chistochina river. Since the publication of the bulletin, copper deposits have been found in the Valdez Creek country within the area of basic lavas shown on the geologic map given in that report. Platinum has also been found in the Slate Creek gravels.

AMMONIA amounting to 130,000 tons of NH_3 per annum is the capacity of by-product coke-oven plants at work or being erected in the United States. In normal times most of the ammonia, as sulphate, is consumed as fertilizers; but at present other compounds are necessary and plants are being altered accordingly.

Drilling on the Lena Goldfield, Siberia

By W. E. THORNE

Early in 1915 I was asked by the Lena Goldfields, Ltd., of London, to go to Siberia and organize the drilling operations intended for sampling these celebrated alluvial mines in the Bodaibo region, and to advise as to the possibility of applying either mechanical or hydraulic methods. The cost had been so excessive that it was thought desirable to change the method of operation.

When I arrived I found drills scattered all over the property, which is 250 miles long by 100 miles wide. The company owns 45 Keystone drills, 38 being in operation. Before my arrival about 20 were in use, the others being under repair. Most of them are No. 3 traction; others are No. 4 traction, and non-traction. Each machine was operated as an independent unit, as if it belonged to a separate company. Spare parts and supplies were carried with each machine. If two machines were working even within a short distance of each other, and something should break on one of them, it would be obtained from the main supply-station; possibly the other machine might have the part required, but a transfer would not be allowed. No special reason was given for this, except that the drill-foreman said that he was charged with each separate part, and if he let the other man have it, he would be short. A great deal of time was lost thereby. One of the first things I did was to concentrate the machines, so that never less than two machines were working on the same ground, and as many as six were working within 600 ft. of each other. By so doing, we reduced the number of spares that it was necessary to take from the warehouse at one time. Instructions were given to the drill-men to borrow from each other; all that was required was a receipt from one man to the other. They were instructed to assist each other as much as possible in order to expedite the work. Thus we were able to introduce team-work into the organization—something they had never known before. I asked the drill-foreman and workmen to submit to me any scheme that they thought would improve the efficiency. They were to make a sketch of any change they thought useful, or write me a letter stating their views, and I would take it up with them; it was understood that any good ideas would be adopted, and that they would receive credit for them. This was a thing that they never had been permitted to do before, as they told me that the Russian technical man absolutely refused to consider suggestions from the workmen; he said that, as the workmen were non-technical, it was not possible for them to know what was best.

As a result of this concentration and team-work, our results, at the end of the first year, showed an increase in efficiency of 32%, with no increase of cost. The best

record was made during August 1916, when our cost was 59% lower and our speed 55% greater than formerly. This was done under adverse conditions; for the previous season's record was made prior to the War. Some of our best drill-men had been mobilized; also we were short of supplies, and were required to repair and to re-construct a great many badly worn tools, which, under normal conditions, would have been scrapped. In 1917, after the Revolution, the cost increased about 62% and the efficiency decreased 11%; this was due to the exorbitant demands of the workmen, plus the high cost and shortage of material. It became necessary to make our own couplings, shoes, and drive-heads at the mine. These parts cost about four or five times as much as if ordered from the factory. Labor conditions became almost prohibitive. The laborers demanded an eight-hour day with an increase in pay of 105%; they also demanded the right to rest when they pleased, to have extra men on the machine, and to be given time to smoke. As to smoking, they insisted on the right to smoke three times per hour, this consuming 10 minutes. When they did work, it was in a half-hearted manner, as though they knew that their jobs were permanent and that they would not be discharged. We consented because we had no choice in the matter. No discharge of a workman could be effected without passing it first through the hands of two committees, the group and the head committee; then it went to the general manager, but his decisions always confirmed that of the head committee. A lack of backbone, I think, was the reason for this.

The old system of keeping records was very poor. With the aid of my chief assistant, A. L. Matsusovich, we arranged a new system. First came the 'log' or record of each hole; this included all the essential facts in reference to the work, such as depth, cost, character of material, average per cubic yard, and time. These figures were forwarded to my office as soon as the hole was completed; in the majority of cases it was received within 24 hours. By glancing over this sheet, I could ascertain if there was any delay or excessive cost. Every foreman and superintendent had instructions to report once each day by telephone to my office. If there had been any excessive cost or delay, the question was immediately taken up and the reason ascertained. Originally the journal, or day's record, was made in triplicate, written out laboriously by hand by the drill-foreman. He might have to write six before getting three complete copies. This took a lot of his time and was unnecessary. Under my direction he wrote one copy; that came to the head-office, and from it the others were typed and signed by the assistant; one copy was kept in the office and the others

forwarded to Petrograd. In this journal were given the position of the hole, the name of the claim, the depth to bedrock, the water-level, and so forth, even segregating the items of cost, the total cost for each hole, the cost per foot, the average value over the total depth, and the average value over what would be considered drifting depth, usually 7 feet.

The method of calculating average values was what is known as the Radford formula. This, as I understand it, assumes that 100 linear feet of 6-in. pipe, with 7½-in. shoe, is equal to one cubic yard in place. This I changed, using 81 linear feet for the 6-in. pipe. In some parts of the work, I made a reduction of 10%, and in others 25%, for safety. In part of the ground it is impossible to drive the pipe before drilling; consequently it became necessary to drill below the pipe, then to drive, and afterward to pump. This is not the best practice, but under the conditions that prevailed in this part of Siberia, there was nothing else to be done. That is one of the reasons for the use of safety-factors. Subsequently we put down shafts on some of the drill-holes, and also checked the bottom 7 ft. of the drill-holes by underground workings. In a few cases the results did not check. This was accounted for by a boulder coming in before the shoe, and, in drilling ahead of the pipe to break this boulder, sometimes the boulder would be driven down for several feet before reaching solid material where it could be broken. If this happened, then the gold would be carried down with the boulder; as a result the drill-hole would show an enrichment at this point; whereas, when a drift-sample was taken, it would not have such a concentration, and therefore would show a lower value than the drill-hole. Where the conditions were suitable, even in rich ground, the checks were within 2%, which was close enough for the work that was being done. While it is possible that some of the drill-work was carelessly performed, I came to the conclusion that there was more loss from careless washing than in the actual sampling. In some of the old records, I found that they had never taken into account any value under 45 milligrammes per foot of pipe. Of course this old work was ignored and the ground re-drilled. In the new work I had one drill-man check the work that he had done two years before under the old management. His new work showed more gold than the old. This raised a doubt as to the correctness of the last drilling. I asked the drill-man to give me his version of the matter. This he did, by describing the method used; that was to take one pumping from each foot of hole, put it in a grain-bag, which was left on the ground where it became solidly frozen. The samples were taken in a wagon and hauled about two miles to a washing-plant. The bags were placed in a tub of warm water, allowed to remain there for a few minutes, and then were dumped into the washer. Frequently not more than half of the material had thawed, the other half still remaining frozen and adhering to the bag. The bag was shaken over the washer and thrown aside. The foreman told me that

bags had been returned to him with fully half the sample remaining in them. As the material was wet when dumped into the bag, the gold would sink through and concentrate at the bottom of the sample. As that was the part adhering to the bag, of course the richer part of the sample was never washed. Hence the discrepancy.

In my sampling of alluvial tin deposits in Portugal and Nigeria, I have had the same trouble with boulders found in front of the shoe; the ground not being hard, the boulder would travel ahead of the shoe, sometimes several feet, before being broken. When broken either rich concentrate was obtained, or the boulder might have been driven a little to one side and the greater part of the sample lost. In one instance, in Nigeria, in a line of holes where the samples had been good, one drill-hole showed an exceedingly low return. The foreman was a good worker, and he knew that the sample coming from the hole was too small. When he came in at night he explained the trouble in detail, and I instructed him to drill another hole about 18 in. from the first. His return from this second hole was about 9 lb. of cassiterite per cubic yard. We then eliminated the old hole and used the new one. The dredging results in Portugal and Nigeria showed a higher return than the drill-tests. This is explained by the fact that most of the tin deposits are loose and the boulders in the material would cause trouble. Also part of the drilling was done with the Empire drill, using the working-pump only. By this method we depended solely on the slosh of material to get it above the ball-valve in the pump. This does not work successfully. One set of drill-holes in Nigeria showed 3.5 lb. cassiterite per yard, and the dredge returned about 5 lb. per yard. This, of course, is on the safe side, but there are places where such differences might be sufficient to condemn a venture. The best way to avoid this inaccuracy is to drill more holes and to use a suction-pump.

As soon as I suggested that possibly some of the Lena ground might be worked more advantageously by dredging, the Russian engineers on the property said it was impossible, because all the gold was in the bedrock. In order to test this statement, I requested A. J. Heindel to make a graphic presentation of the gold in each hole. This he did, and, as we had a cross-section of each line of holes, when the values were shown graphically on this section, one could see where the gold was concentrated. After having completed a few of these it was definitely settled that fully 98% of the gold was above bedrock. Even if it had been on the bedrock, there was no reason why the dredge should not have recovered it, as the bedrock is sedimentary just as in the Klondike and in Alaska.

The drilling machines are numbered. A map on a scale of 175 ft. to the inch was used. On this each line of holes was marked, and also each hole. A pin with a number represented the machine. This pin marked the point where the machine was drilling. If a machine was in the repair-shop, or was being moved, it was indicated by a pin stuck in a card hanging on the wall. There was

a black blank on this card, so that each 24 hours of work could be marked with chalk, indicating every day the site of each machine, and the progress made, so that anyone wishing to know anything in reference to the drills could walk into the room and see at a glance just how things were progressing. This is of great assistance to the office-man, for when some foreman telephones for 'spares' and gives the field-number of his machine, by a glance at the card one can see if it is a No. 3 or a No. 4, and then send out the right spare parts. The sending of the wrong parts was a serious handicap before this system was adopted, as I know of cases where they were sent 150 miles and on arrival were found to be not what was wanted. A tabulated sheet was prepared at the end of each month and sent to my office by each superintendent, giving the total amount of drilling for the month for each machine, the number of the machine, the name of the foreman, and other details. These tabulations were compiled at the end of the year and each foreman was given credit for the work that he had done. A large sheet was prepared from all the records at the beginning of each month for the previous month's work. This sheet when completed was forwarded to the office at Petrograd, copies always being retained for my office.

By this system of cost-keeping we were able to work out an accurate method of distribution of costs. Average costs for the year were proportioned as follows:

	%
Workmen	45.6
Superintendence	9.7
Horses	8.1
Wood	32.9
Material	1.7
Repairs	2.0

The excessive cost for wood was caused by using wood for bonfires, to give light when at work. The winter work was done when the thermometer registered -70° F. I advised the company to operate only about nine or ten months of the year, stopping during the excessively cold weather, meanwhile making such repairs as might be needed. We used manila rope. In the very cold weather this cable would begin to freeze and accumulate ice, until sometimes it was four inches thick and would barely enter the pipe. When it became necessary to lower a string of tools to disconnect the cable, it was like a bar of iron. When it did finally bend, it was usually at the socket; about one-half or two-thirds of the cable would break off, and it was necessary to put the socket on again.

Too many different standards for repair parts were in use; for instance, there were five different sizes of couplings for the 6-in. pipe. This was due to the fact that couplings were furnished partly by the Keystone company and partly by Russian companies; but some of the other sizes were unexplained, until, in talking it over with one of the mechanics who did most of the work at the head machine-shop, I learned that sometimes a pipe that had been much used would be returned to the shop. The threads might be good on the end, but being worn it was of smaller diameter. The drill-foreman would instruct

the mechanic to make a new coupling to fit this thread. In consequence, when the coupling was taken off and an attempt made to fit it to another joint of pipe, it would prove too small. I have seen the drill-men attempt to put on a new section of pipe when drilling; they would try every piece of pipe they had and yet be unable to get a good fit. This caused much loss of time. Accordingly orders were given that all couplings must be standardized and all pipe-threads cut to fit these standard couplings. All these standard ends on couplings were marked with a diamond cross, thereby enabling the workmen to identify standard couplings and pipe at a glance. This standardization was not put into effect all at once; to do so would have been almost impossible under the conditions as it would have required at least six months, but it was done as often as a pipe came in for new thread, or when new couplings were made, some of the old couplings being turned to a little larger diameter. Our standard coupling was made by a Russian firm and was slightly larger in diameter than the Keystone coupling. We could turn out the Keystone coupling to a larger diameter, but could not shrink the Russian coupling to a smaller size.

On leaving for the mine, I was advised by some American engineers, who had had much experience in Russia, that it would be impossible to get efficient work out of the Russian drill-men. This proved to be a mistake. Russian mechanics and workmen can do good work and will do it if properly directed. They do not accomplish as much as American workmen, but what they do, in most cases, is well done. As an illustration, in 1913 I was in the same district with five American drill-men and they accomplished about three times as much work as the Russian drill-men. One reason for the lack of efficiency of the Russian workmen is, I think, the lack of practical experience on the part of the technical staff. The Russian engineer has a good technical education, but as for practice or doing things with their hands, from my experience among them I would say that 99% of the Russian engineers are deficient. Of course, having no practical experience, they cannot direct the workmen as they should. The Russian idea is to measure organization and efficiency by the number of men that they have doing a piece of work. A foreign engineer is all right in Russia if he can take over a piece of work and figure out some scheme to put on more men, but if he begins to reduce the force and accomplishes the same amount of work with less men, they immediately begin to raise objections. They believe in doing things by hand labor. I have seen them put a rope on the end of a large 3-in. plank that was water-soaked and very heavy; five or six men would take hold of this rope and drag it for 100 ft. or more. At the same time a horse and cart would be standing idle alongside. The time it would take to attach the rope to this cart and drag the plank to the point where wanted would have been 10 minutes. These five or six workmen would put in at least one-half to three-quarters of an hour getting the plank in place, because they must stop to smoke, and talk, and rest during the process. This operation was the

fault of the technical man in charge; he stood calmly by while the work was going on, seeming not to realize that the workmen were wasting time. One cause for a great deal of trouble in attempting to organize work and to make the workmen understand what is wanted is the inability of a man to speak the Russian language and to understand it. If one depends on an interpreter to translate orders to the workmen poor results are obtained. Usually the interpreter is a non-technical man and has had no practical experience in the work that is being done; therefore he is likely to convey a part of the instructions mixed with some of his own ideas, which is confusing and causes a great deal of trouble between the foreign engineer and the workmen. After an engineer is able to speak the Russian language and can give his orders direct, he will find that his troubles have been greatly decreased.

The production of gold in 1915 from the Leskoie was a little over 18 tons, worth about \$9,000,000. In 1916 and 1917 the output was about 16 tons each year, with 7500 to 8000 workmen employed.

Gold stealing is common. The gold is taken to the Government laboratory at Bodaibo. About \$2,000,000 worth of gold not accountable to the producing mines is received annually at this laboratory. Government officials say that this is stolen gold; as the Lenskoie produces about 75% of the gold shipped from this district, \$1,500,000 of this stolen metal must come from the Lena mines, which produce about 35% of the total Russian output. In 1917 the general manager conceived the brilliant idea of bribing the workmen to be honest. He offered to give them \$1,500,000 per annum, to be divided among themselves as they saw fit. This proposition was made to the head committee, the members of which answered that they would take it under consideration. Shortly afterward they came back with a counter proposal that if the company would give them \$5,000,000 per year they would not steal any gold. This was not accepted. The company is itself to blame for the stealing. In early days the managers started the practice of paying the workmen a premium for each large nugget turned in at the head office. Of course, the nuggets picked up by the miners became smaller in size, but the premium was still paid. Soon the miners found that they could get more money from some outside buyers; in consequence the company had to increase its premium and the illicit buyers increased theirs, until now the Lenskoie company gets no stolen gold unless it pays the same price as the other parties. Early in 1915 one stolen nugget weighed 18 lb. This was abstracted within 25 ft. of a watchman. The nugget was taken away and sold at Bodaibo; the company knew nothing of it until a miner while drunk gave the tip. It will be impossible to stop this stealing under the present Government.

The present methods of underground work are about what they were at the beginning of operations. A great many suggestions have been made for improving them, but it is difficult to introduce any improvement among

people that object to doing anything that their grandfathers did not do. On some of the ground where I advised the use of dredges the unit of calculation is the sajene, which is 7 ft. In driving, each 7 ft. square of bedrock by 7 ft. high costs about \$100. The average depth of the ground is 70 ft. The average gold content of this ground when driven is \$75 per 7 sq. ft., showing a loss of \$25 per sajene. The same work can be done by dredging at a cost not to exceed \$25. I showed them by figures that where they were losing \$25 there would be by dredging a possible profit of \$75. It was a long hard struggle to convince them, but they finally came to the conclusion that I was right. In August 1915 they placed an order for one 17-cu. ft. dredge. This was considered at the board meetings, talked over, discussed, and delayed until November 1916, when the order was placed. During the time they were making up their minds for this change, there was an increase of about 40% in the cost of material, and a doubling of the time required for delivery.

Credit for the technical improvements that have been put into operation during the last five years belongs mainly to Leon Perrett, a Russian engineer, who was general manager in 1913 and 1914. The erection of the new plant was directed by R. E. Smith, an American engineer. Mr. Perrett introduced mechanical haulage, also the recovery of timbers from underground workings and the winter-washing arrangements. The winter-washing was not begun until 1914-15, but Mr. Perrett discussed the idea with me in April 1913. I described our practice at Dawson, and agreed with him that it would be practicable. It has proved all that we could have expected. A mistake was made in the first winter-washing plant, the grade of the sluices being only 4%. The flat sub-angular gravel of these mines will not run in a sluice having so slight a grade. The Russian engineer on the mine objected to the 4% grade but could do nothing, in face of the opinion of the consulting engineer, until an experiment had been made. A. K. Schmidt, a Russian engineer, who was in charge of the Fedosiskey mine, then took over the re-construction and increased the grade to about 10%. The sluices have worked well ever since. In 1914 plans were drawn by the consulting engineer to erect a mechanical elevator on the Tichon mine. This was a complicated plant and proved a failure. In 1914, after an examination and some sampling, I informed the secretary of the company by telegraph that dredging was advisable, as there was no possibility of a profitable operation with mechanical elevators. This created a dispute among the directors, who insisted on sending a special commission consisting of H. M. Payne, A. Gernet, and A. Schwartz to investigate. This commission came on the ground during the summer of 1915 and, after an examination, decided that dredges should be bought forthwith.

SULPHURIC ACID, 66°B., is now selling at \$40 per ton. The 50°B. acid, which is absorbed by the fertilizer industry, is quoted at \$23 to \$24 per ton.

Californian Manganese Problem

By GEORGE D. LOUDERBACK

Manganese deposits are widely distributed in California. They have been found at intervals along the Coast Ranges, in the Sierra Nevada, and in the ranges of southern and south-eastern California.

In the Coast Ranges, orebodies are found only in intimate association with the radiolarian cherts of the Franciscan group, in which they occur fundamentally as interstratified layers or lenses, somewhat affected by secondary alteration and the re-distribution of material in fractures, crush zones, or fault-fissures. Deposits carrying marketable ore have been opened at intervals from Humboldt and Trinity counties on the north to San Luis Obispo county on the south, over five degrees of latitude. In the Sierra Nevada, orebodies occur with the cherts of the Calaveras group, in an association similar to that of the Coast Range ores. Manganese minerals are also found at a number of localities in veins cutting igneous and metamorphic rocks. The deposits of south-eastern California appear to be chiefly vein deposits cutting rocks of various types.

SIZE OF OREBODIES. The orebodies are generally small and discontinuous. There are numerous bodies that would yield from 1 to 100 tons of ore, and many that contain from 100 to 1000 tons, also a moderate number with some thousands of tons up to 10,000 or more. The largest producer in the past is said to have yielded nearly 50,000 tons, and is still producing. Previous to the War but little manganese was mined in California; therefore most of the deposits now being worked were then unopened and in part unknown. As hurried work has been done in response to an urgent and supposedly temporary demand, time has rarely been taken to block out ore, or to develop much in advance of the bare necessities of ore extraction. This, combined with the commonly lenticular or otherwise limited form of the orebodies, makes the determination of available tonnage imperfect, a careful estimate being in general much below the probable supply.

CHARACTER OF THE ORES. The chief manganese-bearing mineral in the ores mined to date is psilomelane, with which is associated a subordinate amount of pyrolusite. In many localities manganese carbonate has been observed, and at several properties it is mined as an ore in the lower workings. It is probable that, with more extensive operation, the carbonate will be found at more places, and will be mined in increasing quantity. It is evident that the black ores in many mines originated from the oxidation of the carbonate.

Veins containing the silicate, rhodonite, are found at a number of places in the Sierra Nevada. At a few localities, silicates of manganese have been observed in the

Coast Range deposits, but hitherto only in minor quantities.

Impurities that are most undesirable in manganese ores, namely, phosphorus and sulphur, are either low or entirely absent from Californian ores. Iron rarely exceeds 2% in the Coast Range ores, and is usually less than 1.5; it may rise to 3% or more in the ores of south-eastern California. Calcium in small quantities occurs in some of the carbonate ores of the Coast Ranges, and may reach 5 or 6% in a few of the south-eastern ores. In the Coast Ranges and in the Sierra Nevada, silica is the chief impurity, and practically the only one that demands consideration. Mixtures of silica with manganese in oxidized compounds range from zero to 100% of either constituent; 10 to 20% silica is a common range for the high-manganese ores containing 40 to 45% of that metal. In the ores of south-eastern California, silica is less in evidence, running from 1 or 2 to 10 or 12%, and the ore is more likely to be associated with calcite, barite, and fluorite.

Practically only the higher grades of manganese ore (38% and over) have been marketed in California. Associated with the high-grade ores in many cases are streaks or larger bodies of lower grade assaying from 25 to 38%, as well as ores that, though fairly high in manganese, carry 20 to 40% or more of silica. These are generally left in the ground, or are treated as waste, although of late some ores with over 20% silica have been marketed. It seems probable that a satisfactory method of concentrating these ores, or of otherwise utilizing them, would more than double the available manganese in many deposits, and make it desirable to open deposits that now are unprofitable. A study of methods of concentrating manganese ores, with special reference to the Californian problem, has been undertaken at the University of California under the direction of E. A. Hersam. His preliminary report will soon be available. The U. S. Bureau of Mines has also established a station in Minnesota for the investigation of problems connected with the production and utilization of manganese.

THE PROBLEM OF DEVELOPMENT. The fundamental difficulty in promoting manganese production in California lies in the small size of many of the deposits and in their broad distribution. Scattered small holdings can hardly appeal to capital. To obtain large production, much of the available ore must be mined by the small miners, the farmers, or others who may not have had previous experience in the work. The owner of a small property ordinarily cannot afford to open and develop it much beyond the actual producing face; he cannot store sorted ore piles for shipment in carload lots; he cannot

maintain an expert engineer, geologist, or assayer, and he usually is not familiar with the marketing of the ore. He cannot contract to supply in the future a definite tonnage or a definite grade of ore. This makes it difficult for him to do business with the steel or alloy manufacturers direct, and he either finds it impossible to dispose of his product, or must depend on brokers for sales. The brokers' method of doing business generally has not been conducive to increased production. Individual bargaining, leading to different prices offered to different producers, even in the same district, has created a feeling of unfair treatment or discrimination. Complaints have been made also of long delay in securing payment, and even of non-acceptance of carloads shipped to the East at the expense of the producer, because some grade-limit was transgressed. The small producer cannot tide over such delays nor afford such losses; hence his production ceases. These difficulties could be met largely by the establishment of buying agencies in touch with the field. Although there are many isolated properties, it is also true that many are grouped in limited districts. An agent at a convenient point in each district, provided with storage-space where ore could be delivered as produced, could make a preliminary inspection, weigh, sample, and pay spot cash for a reasonable percentage of the estimated value, the balance to be paid on final assay returns. Ore could be bought in ton lots or more, sorted into grades, and shipped when sufficient quantities of determined grades had accumulated. Ease of marketing, cash payments, and definite price-schedules would stimulate production from small properties. Buyers then would be protected as regards grade of shipments, and all would be benefited.

The pre-war eastern prices of manganese ores ranged from \$8 to \$13 per ton. Freight to eastern points is from \$12 to \$15. Aside from the freight, the cost of mining and laying down at a railroad point has been, for most properties in California, greater than the final price that could be obtained. It is not surprising that there was practically no production before the War. The effect of the War is shown by the rise in production from nothing in 1913 to 150 tons in 1914, to 4013 in 1915, and to 13,404 tons in 1916. If the pre-war prices return, most, possibly all, of the mines must shut-down. As far as the Pacific Coast States are concerned, the mining of manganese is mainly an emergency industry.

SUGGESTED REMEDY. A guaranteed minimum price for a reasonable time would justify an initial outlay for the development of many properties. Such a guarantee would encourage the small holder, would bring in capital for the larger properties, and would stimulate prospecting. I understand that Great Britain has given such guarantees to certain of its mineral industries, assuring a minimum price for two or three years after the end of the War. It is probable that here a Government guarantee of a minimum price for two years, war or no war, would be sufficient to cover any necessary outlay.

If manganese production, under normal conditions, only needed business organization to make it a stable

industry for a few years, it would seem best that an effort should be made to induce private capital to establish such an organization, but it appears that the bulk of the manganese production that might be developed by proper organization and encouragement in the Pacific States must be considered as a war-emergency industry, and the effort and cost of organizing it may not appeal to private enterprise. Its organization by the Government, or through some authorized public agency, would seem to be the surest and best solution, as it sustains the confidence of the prospectors and producers.

Heating of Coal in Piles

By C. M. YOUNG

*Bituminous coal piled in heaps or bins tends to heat spontaneously through the absorption of oxygen. It seems probable that the first absorption of oxygen by coal which has not previously been exposed to the air may occur as a condensation of oxygen in some form which does not produce carbon di-oxide. The absorption of oxygen is accompanied by an increase of temperature, and this in turn accelerates absorption, and so on, until the kindling point is reached. A dangerous rise of temperature can be prevented by excluding oxygen, by increasing the bulk of coal in proportion to its exposed surface, or by circulating enough air to dissipate the heat produced.

The size of the coal is important, for, if the lumps are small, the spaces between them constitute a small percentage of the total volume, and little oxygen will be available unless circulation of air brings a fresh supply. With large lumps the percentage is relatively large, and circulation also is much easier. Attempts have been made to prevent heating by circulating sufficient air to remove the heat generated, but this method cannot be applied to fine or mixed sizes. At the University of Illinois an attempt has been made to use so much fine coal, and to pack it so thoroughly, as to prevent circulation of air through a pile to prevent heating. The method has been fairly successful. Investigations made on opening such piles showed that the portions in which fine sizes were present in largest proportion did not contain sufficient oxygen to heat the coal to any noticeable extent. The close packing had also obstructed circulation so that little fresh oxygen could have been brought in even if the temperature had been raised to such an extent as to favor circulation of air. This indicates that one comparatively safe way to store coal is to use enough of the fine sizes to fill the interspaces as completely as possible, and to pack the coal tightly in order that the air space may be reduced and the circulation of air restricted.

MEMBERSHIP of American Federation of Labor has grown from 50,000 in 1881 to 2,371,434 in 1918.

*Abstract: Article to be presented at February meeting of A. I. M. E.

REVIEW OF MINING

NEW YORK

Financial.—Taxes.—Commandeering Platinum.—Daylight Saving.

The financial situation is a reflection of the Russian situation and is influenced, moreover, by the definite prospect of a Liberty Loan issue in the near future. Japanese bonds have recently reached a new low record for the year, after having appreciated in value steadily since 1914. Up to the present time Japan has made huge profits out of the War and has used these profits, in large measure, to retire Government bonds. If the country takes a more active part in the War it is likely that all the available capital will be needed for the prosecution of a vigorous anti-German campaign in Siberia. Hence the lack of support toward Japanese issues during the past week. Liberty 4's remain around 96, and show no indication of responding to the consideration that they will, in all probability, be convertible into the forthcoming new issue at par. The maintenance of a comparatively low price-level in these bonds is attributed to extensive selling by some subscribers to the last loan who are anxious to demonstrate their financial ability to take up the new issue in even greater quantities. To do this they are obliged to liquidate their present holdings. All Liberty Loan bonds have therefore declined during the past week. The question of eliminating the \$50 and \$100 denominations in the next issue has been frequently discussed, and it has been pointed out that the investor with limited means at his disposal can invest in Thrift-Stamps and War-Savings Certificates. In spite of extensive publicity, the soundness of the War-Savings Certificate scheme is not appreciated or understood to an extent that it might be; if this were realized it is doubtful if small investors would buy Liberty Bonds at all. Up to \$1000 can be invested in War-Savings Certificates and, unlike the Liberty Bonds, there can be no market depreciation of capital value. The interest accruing compares favorably with that of the last Liberty Bond issue, and few will object to the fact that this is payable at maturity rather than in semi-annual instalments. An additional feature in favor of War-Savings Certificates is that these are redeemable at any time before maturity (January 1923) for the full amount paid, plus 3% interest, the redemption being done by the Government without expense to the investor. Considering the security, the conditions are favorable and even attractive, and it is therefore somewhat difficult to see the reason for the issuance of Liberty Bonds in small denominations, maturing at some far-distant date, when War-Savings Certificates would seem to already cover this particular field. As long as the Government obtains the necessary funds to continue the War, it is immaterial as to whether investors hold War-Savings Certificates or Liberty Bonds. As the former are more easily negotiated and do not depreciate by open marketing, it may be deemed an unwise policy to overshadow the advantage of investment in them by making expensive efforts to induce the investor with small income to subscribe to Liberty Bonds. If this type of subscriber is to be encouraged the new loan must mature within a reasonable date, so that depreciation in capital value will not occur to the extent it has with previous issues. The se-

curity behind Government issues is recognized as unquestionable, but there is no particular reason why war loans should not possess one or more features of financial attractiveness. If this were so it might be possible to reduce the initial expenses connected with the insuring of subscriptions. The attractiveness of the Savings-Bank system must not be overlooked. In New York State alone about sixty of such institutions paid nearly 4% on deposits during 1917, this comparatively favorable rate being largely responsible for the fact that the total deposits were maintained at two billion dollars, as estimated on December 31. In the matter of the cost of placing the next loan, New Yorkers are interested in a proposal to cut up part of Central Park to represent a mimic battle-field. An appropriation of \$25,000 has already been made for the purpose of replacing the sod after the damage has been done, although it is generally admitted that this will only cover a fraction of the expense involved. Whether anyone will feel disposed to purchase a bond after viewing the results of such an apparently unnecessary expense and waste of labor in this time of great national emergency, is open to question. The ratification of the Russo-German peace treaty was followed by a moderate rally in the valuation of Russian bonds, a happening that apparently indicates the value, in financial circles, of 'peace at any price.' Anglo-French and British bonds, uninfluenced by the prospect of additional issues in this country, have hardened and show appreciable rises.

The tax-rate for New York City shows a considerable increase over last year's levy. The budget for 1918 calls for a total of \$239,023,759. Toward this amount the county dues amount to \$7,400,523, and \$38,233,017 is estimated as the probable revenue from the general fund. The balance, \$193,390,208, must be met by taxation on real and personal estate representing an aggregate valuation of \$5,591,057,726. Nearly three-quarters of the entire city's taxation will be met by the borough of Manhattan.

The commandeering of platinum by the Government has brought home to part of the jewelry manufacturers the fact that 'necessity'—especially military necessity—'knows no law.' The first result of the order has been a brisk demand on the part of the public for platinum jewelry of all kinds, and the remaining stocks will soon be disposed of. Platinum is irreplaceable as a satisfactory mountant for white diamonds. This is largely on account of its non-oxidizing properties, and the ease with which it may be worked in the pure state. Its proximity to a brilliant adds lustre to the latter, and no effective substitute is known. Gold alloys, carrying even 25% of base metal exclusive of copper, invariably have a green shade, a color altogether unsuitable for white diamond mountings. The local refiners are now busy on a substitute for platinum, and it is probable that the Government order may stimulate research which may lead to important discoveries.

No more efficient or less harmful method of economy was ever proposed than the daylight-saving plan which, it is earnestly hoped, will soon become law. It is strange that the scheme has found so few enthusiastic sponsors, although not remarkable that no dissentient voice has been heard—for the advantages to be gained are too obvious to warrant more than passing comment. The merits of the

scheme have been obscured or 'damned with faint praise' to an extent that suggests the obvious inference that 'daylight saving,' as a financial gain to anybody, was not worth advocating, much less exploiting.

The suspension of work at the largest smelter in Mexico—the Aguascalientes plant of the American Smelting & Refining Co.—is announced as due to the arbitrary taxation demands made recently by the State Government, which apparently fails to realize when it is well off. For once a company strikes and 2000 Mexicans are idle. It is thought probable that the prompt refusal of the A. S. & R. Co. to consider the imposition will cause the authorities to modify their demands, who may see in the idleness of their countrymen an additional reason for an equitable agreement.

DENVER, COLORADO

Accidents in Colorado Mines.—Manganese Production.—Colorado Fuel & Iron Co.—Oil-Shale.—Molybdenite Mills.—Flotation of Dump Ore.

According to a statement by Fred Carroll, State Commissioner of Mines, metal-mining accidents are on the decrease in Colorado, although the betterment is slight. Against fatalities of 67 during 1916, the 1917 death-list was 58. The greatest hazard continues to be from falls of rock, with falls down shafts second in point of danger. Of the total 1781 accidents last year, only 703 required the victims to be absent from work more than 14 days. When it is reflected that many inexperienced men have, owing to war labor conditions, become miners recently, these statistics are encouraging for still better conditions this year.

Anticipating action by the War Minerals Committee at Washington in raising the prices of manganese ore, the Colorado Metal Mining Association has inquired why this State has not been more active in the winning of this mineral, and finds that the sole reason for the backwardness has been the ridiculously low prices purchasers will pay for the ore. Miners have become tired of producing manganese when the chances for profit are but a few cents per ton and are frequently in red ink. They will respond promptly to any encouragement given them in the way of fair prices. The Association has been informed that it will be duly advised by the War Committee when it fixes prices for not only manganese but for tungsten, vanadium, and molybdenum ores, all of which can be produced in fair quantities in this State whenever a profit is assured.

It is the conclusion of the oil-shale men in Colorado that future filings on these shales will be regulated precisely as are filings on ordinary oil-lands, that is, by the provision of sections 16 and 17 of the Walsh-Pittman bill, which has passed the Senate and is expected to become a law within a short time. According to this bill, all persons who have already initiated oil-shale claims under existing placer laws and who proceed regularly to develop such claims will not be molested. The bill further provides that all bona-fide locators of such claims who choose to do so may surrender their rights to the Government and be given prospectors' permits with priority privileges for leasing the same tracts under the stipulated one-eighth royalty. A severe test will probably be applied to all locations of such land prior to the passage of the bill and no person who can be proved guilty of fraud will hereafter be entitled to any benefits under the new law.

Pueblo.—The last semi-annual report issued by J. E. Welborn, president of the Colorado Fuel & Iron Co., states that, although the number of employees has increased but 15% in the last two years, the average wage paid has increased more than \$200 per year, this being the result of the advance in salaries and wages put into effect last November and amounting to approximately \$2,500,000 per annum. The increase in pay does not affect officials. Dur-

ing six months the company mined 407,714 tons of coal, produced 409,483 tons of coke, quarried 219,653 tons of limestone, smelted 196,902 tons of pig-iron, and manufactured 232,888 tons of finished iron and steel products in its Minnequa plant near Pueblo. Receipts for the half-year period were \$20,739,030, and expenses \$17,029,735. By adding income from sources other than operations, the net income was \$4,123,875. The surplus, after deducting all fixed charges, was \$2,678,289. Of the \$1,000,000 subscription placed for the second Liberty loan, this company was allotted \$612,000.

Leadville.—The two mills of 250-ton capacity each, which have been under erection this winter by the American Metal Co. and the Molybdenum Products Co. at Climax on Fremont pass, are practically finished. These companies own property close together at an elevation of about 11,300 ft., the orebody being a great mass of porphyry carrying about 1% molybdenite. A third company is opening another near-by property with the intention of treating its ore in the plant of the Pingree Mines Co. at Leadville, which is only a few miles to the south. In all these properties the mineralized rock outcrops and can be mined by open methods during the summer. To provide tonnage during winter, adits are being driven into the formation. Particulars regarding the MacCarthy process, to be used in the Molybdenum Products Co.'s mill, are kept secret. The American Metal Co. flow-sheet includes crushing, grinding in ball-mills, flotation in Callow and Janney machines, and dewatering of concentrate in a Portland filter.

Georgetown.—The Colorado Central is pushing construction of its plant at Georgetown to handle 1000 tons daily from the dumps of the Ocean Wave and Marshall Tunnel mines. Investigations of these dumps show the former to contain 59,000 tons running \$4.35 in silver, lead, and zinc, with 176,000 tons in the latter dump running \$3.15 in the same metals. The gold content is negligible. It is also estimated that these old mines contain approximately \$5,125,000 in low-grade stuff filling old stopes and standing unbroken. The crude dump-rock is first crushed, picked by hand, and screened, this being in the nature of crude concentration in the ratio of 5:1. The mill proper takes this selected feed and passes it through Colorado Iron Works tube-mills and over Deister-Overstrom tables, the reject from the tables going to four specially designed 6-cell flotation machines. The mill will probably not be completed for three or four months. Henry Kroger is president; C. L. Woods is vice-president; and E. S. Wiard is consulting engineer and manager.

ELY, NEVADA

Labor Troubles.—Manganese and Oil-Shale.—Aurum District.

Weather conditions have been bad during the past month. On account of rain and snow roads are soft and no hauling of ore has been possible, except by the large companies who have rail facilities. There has been no coal shortage for two months.

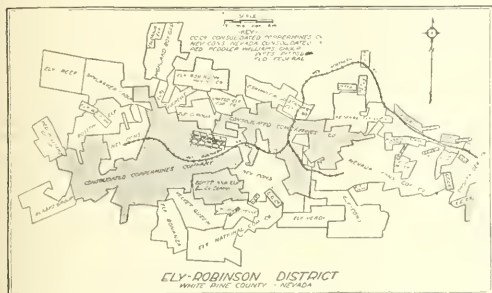

At the Nevada Consolidated Copper Co.'s mines, mill, and smelter, employing about 3000 men, there have been some labor troubles during the past month. Men demanded an increase in wages because of high cost of living. The company at the mines, until February last, has charged its employees only \$25 per month for board, room, light, and fuel; nor has there ever been any cause for complaints concerning the quality of board or quarters. But the board expenditure finally rose to \$32.55 per month per man, and the company raised its charge to \$30. The company advanced wages 25c. per day per man, except for common labor, and paid all of them this rise on the March pay-day for past two months—January and February—which was

delayed until March 11, as a new roll had to be made out. Then the different unions began quarreling among themselves. Some said that they were entitled to more than others. Carpenters stood out a long time, but it is thought at present that their troubles are over for a time. The Ruth mine has its daily production up to 3500 tons. All the Nevada Consolidated mines are yielding 1400 tons daily, steam-shovel operations supplying 10,500 tons. Since the large new crushing-plant was finished last fall there has been little trouble with ore freezing in cars and bins, because there is sufficient storage capacity to dump it from cars in three to four hours, while the crushers handle any size pieces.

Since the above was written, we learn that the rise in price of board was not put into effect. Also, firemen, engineers, and switch-men struck on March 19, stopping steam-shovel work. Ruth mine continues to work. The mill is working at less than half capacity, due to shortage of ore.

Robert M. Linton, general manager and consulting engineer of the Consolidated Coppermines Co., has been in the district for some time recently. The 1000-ton plant at Kimberly was started early in March.

Holmquist and Bowen, working a manganese deposit 7 miles south-east of East Ely, are only doing development.

All of their workings are full of broken ore, which cannot be hauled owing to bad roads. Three different openings in limestone at 30 ft. depth have exposed large bodies of shipping-grade ore, 40% or better, each several hundred feet apart. At depth of 60 ft. in one shaft, they have a good deal of 60% ore.

The Ward mine, across the valley, 8 miles of the manganese deposits, at an elevation of 8000 ft., is only being developed because of bad roads. Owners could easily ship 100 tons daily indefinitely, but cannot transport it. They would probably put down a narrow-gauge railroad with Holmquist and Bowen, for shipping their manganese, if equipment could be procured.

The Lucky Deposit mine at Aurum, in the north-east part of White Pine county, has been examined by the U. S. Smelting Co. and others. This is a copper property from which Gilmore brothers shipped a number of cars of 8% copper and \$6 gold and silver ore, from Currie, last year. They had a haul of 60 miles by auto-truck, but there is a new spur put in three miles below Cherry Creek station, on the Nevada Northern railroad, and by hauling over Shellbourne pass, when roads permit, the distance is cut nearly a half. The property is said to be opening well.

A recent discovery of oil-shale in Steptoe valley is peculiar. When freshly broken, or scratched with a knife, a distinct odor of gasoline is noticeable. Shale is white, crystallized, and largely silicious, from the metamorphic action of the intrusive rhyolites through the shale. Pieces put in the fire explode with considerable force. Some locations have been made.

More patent work has been done during the last year throughout the county than for several years. The present administration of the Land Office, under a Western man's management, who is familiar with conditions, is more liberal than for years past.

SUTTER CREEK, CALIFORNIA

Principal Operations in Amador County.

Amador City.—The Bunker Hill Mining Co. recently levied an assessment of 10c. per share to provide funds for extensive development, including, it is understood, the sinking of the shaft and opening of new levels. This mine has a good record and there is no doubt as to its value in depth, but development is necessary to make it a dividend-payer again. Until the strike in 1916, the Bunker Hill mine had not missed a single monthly dividend for about ten years. Considerable money was spent last year in straightening a bend in the lower part of the shaft, also preparing to sink below 2400 ft. C. E. Bunker is general manager, and W. F. Detert, E. C. Voorheis, Arthur Goodall, and C. L. Culbert are directors.

Jackson.—The Argonaut mine made another fine run in February, the clean-up from the 60-stamp mill yielding about \$85,000. This property adjoins the Kennedy, and includes what is known as the Kennedy Extension property. N. S. Kelsey has charge of operations.

Sutter Creek.—Old Eureka Mining Co. has been engaged for the past week in cutting a station on 2200-ft. level. When the timbers are in place and ore-chutes built at this depth, sinking will be resumed 1000 ft. below the former bottom at 2165 ft. before commencing extensive development either in the new ground thus opened or levels above.

The plant of the Oneida mine, controlled by the South Eureka company, is being dismantled. Track and pipe are being removed from the shaft. Levels connecting this mine with the South Eureka will be bulkheaded so that pumps in the South Eureka shaft will not have to lift more than the water produced by the Central Eureka and South Eureka mines, which are at present kept free from water by means of a joint pumping installation in the South Eureka shaft. In the event of the South Eureka mine discontinuing pumping operations, upon notice being given in accordance with contract, the Central Eureka company will assume the expense of keeping the two mines unwatered. The South Eureka company will now dispose of some of its machinery. It is improbable that mining or development will be resumed there until after the War, as present conditions render operations unprofitable on ore opened in the South Eureka.

The Central Eureka company's shaft is being deepened. Two crews of four men each are working under contract. The shaft has reached a depth of 3490 ft. After providing a sump, a station will be cut on the 3500-ft. level, before sinking deeper.

MINNESOTA

Exploration Near Keewatin on Mesabi Range

Keewatin.—Drills of the Carlson Exploration Co. on Mesabi range, which have been operating on the forty west of Keewatin for more than a year, have been removed to Virginia. No more drilling will be done on this property for the present. It has been known for some time that there was a deposit of iron here, and drilling has been carried out in a systematic manner to determine the amount, grade, depth, and shape of the orebody. Many of the holes were placed at 50-ft. intervals to accurately determine the shoreline and limit of surface stripping. This property has been leased by the Wisconsin Steel Co., and it is expected that important operations will be started shortly. The ore developed has shown strong possibilities for both underground and open-pit methods.

THE MINING SUMMARY

ARIZONA

Ajo.—New Cornelia company on March 7 had a successful blast set off. There was 50,500 lb. of 40% Trojan powder charged in 8 holes. Estimates place ore broken as 200,000 tons.

Bisbee.—Wolverine & Arizona produced 1200 tons of 5½% copper ore in February. Of this, 90 tons came from old oxide stopes at Higgins end of property, and averaged 9%. Main workings are near White Tail Deer mine of Copper Queen. No. 2 shaft is down 340 ft., and is being deepened. Cash on hand amounts to \$100,000.

Clarkdale.—Poston & Blumfield of Colorado Springs have acquired some copper claims in the Squaw Peak district, on the Mesa-Clarkdale railroad. A camp is to be erected and operations commenced at once.

Globe.—Globe Dominion Copper Co. is to install pumps to lift five times present flow of water. The machinery has been purchased.

Jerome.—Green Monster has developed considerable 1½ to 2% copper ore in its Cliff claim. A winze is being sunk below 400-ft. level to prospect the contact further. Some low-grade copper-silver ore has also been found at 500 ft. depth in the Revenue claim.

Oatman.—United Eastern in February produced gold worth \$146,500 from 7040 tons of ore. Average was \$20.80 per ton, and extraction 96.91%. Profit amounted to \$88,750.

Parker.—Water-level has been reached at 640 ft. in shaft of Empire Arizona Consolidated Copper Co. Cross-cutting will be commenced at 200 ft., as soon as shaft reaches depth of 700 feet.

American Eagle property has been purchased by W. H. Thorpe and associates and a lease obtained on the Roberts claim.

Prescott.—Copper Valley Mining Co., recently incorporated, which took over the old Ehle claims in Skull valley, has commenced operations. The 75-ft. shaft is to be sunk to 500 feet.

Sale of Buzzard and Raven claims to an Eastern syndicate is creating considerable interest in the district. J. B. Tomlinson is in charge.

Tombstone.—Huert company has just completed a plant for treating tailing from old Contention dumps.

Compressor and other machinery is being installed on property adjoining the Broskaw claims. A mill is to follow to treat vanadium ore, which is claimed to have been discovered in large quantities.

Tucson.—Arizona-Tonopah M. & M. Co., in charge of George Ankers, has acquired Gold Coin mine in Pinan district, Riverside county, California. Mill is to start treating ore at once. In its Arizona mine, 8 miles south-west of Tucson, 12 ft. of 4% copper ore has been opened. Company controls 994 acres in the two States.

Wickenburg.—Hand-jigs at the old Smith wulfenite mine, 12 miles north-east of here, are producing concentrate. One, working 8 hours, yields 300 lb. of 5% MoS₂ concen-

trate in the apron, and 50 lb. of 25% product in the basket of the jig. G. E. Johnson Jr. is owner of this molybdenum mine.

Mayer.—In the March 'Yavapai,' a monthly published at Prescott, mining in this district receives considerable space. We reproduce a map showing the more important proper-

MAP OF MAYER DISTRICT, ARIZONA

- | | |
|---------------------------|-----------------------------------|
| 1. Con Arizona Smelter | 22. Half Noon |
| 2. Silver Belt | 23. Rio Tonto |

| 21. Arizona Copper Hill | |

ties. At Humboldt, the Consolidated Arizona Smelting Co. employs 600 men, producing 2,000,000 lb. copper monthly. The Arizona-Binghamton Copper Co. at Stoddard has developed a large property, and concentrates 5000 tons of ore per month, sending product to Humboldt smelter for reduction.

ARKANSAS

Yellville.—Activity continues in the zinc-lead districts of northern Arkansas, in spite of long haulage and cost of

supplies. South-east of Yellville the Cowan Barrens Development Co. has started drilling.

Zinc.—Four custom mills are kept busy here, and mines are reported as opening well.

CALIFORNIA

Oil production of this State in February amounted to 272,667 bbl., against 270,990 bbl. in January. There were 3158 wells producing. Completed wells were 51, with an initial yield of 11,090 bbl. In Montebello field Standard Oil Co. brought in its Baldwin No. 6, with 2000 bbl. daily, and No. 11 with 1000 bbl. Stocks decreased 412,087 bbl. to 31,360,378 barrels.

The State Mining Bureau of San Francisco has published Bulletin 77, entitled 'Catalogue of Publications of the California State Mining Bureau, 1880-1917.' With index it covers 44 pages. Brief notes are given on each bulletin published, also whether it is in stock or not.

Bolinas.—Four miles from this small port on the coast of Marin county the Chetco Mining Co. is operating an interesting copper property. It was first worked about 40 years ago; again in 1903, being finally re-opened late in 1917. The vein occurs mainly in metamorphic sandstone, although partly in a shale. Ore is found as shoots, it being an impregnation. It is a sulphide right to surface. The copper mineral is chalcocypite. Openings by shaft and tunnels to 200 ft. depth amount to 2000 ft. A good quantity of ore has been developed. Shipments over 300 tons have averaged 9% copper and 9 oz. silver per ton. A 40-ton mill was started this week. It consists of crusher, Hendy ball-mill, and Overstrom concentrator. Ore being dressed carries 4% copper and 1 oz. silver for each 1% copper. A concentrate containing 12% copper is aimed at. No classifying is necessary. An extraction of 90% is expected, according to tests. Concentrate is to be hauled to Bolinas bay, loaded on schooners, and carried to the Mountain Copper smelter at Martinez on San Francisco bay. About 25 men are employed, in charge of Theodore R. Heintz as manager and D. Walter Carr as superintendent.

Grass Valley.—Golden Center company has decided to levy an assessment to finance deeper development. This action was taken at a meeting of shareholders at Sacramento. C. A. Brockington will continue as superintendent. E. C. Uren has been appointed consulting engineer.

Idria.—New Idria Quicksilver Mining Co. notifies stockholders, for purpose of income-tax returns, that the \$1 dividend paid March 31, 1917, was wholly from 1917 earnings; \$1 paid June 30 was 47c. from 1917 earnings and 53c. from earnings prior to March 1, 1913; 50c. paid October 1 and 50c. paid December 29 were wholly from earnings prior to March 1, 1913.

Ingot.—Afterthought Copper Co.'s roasting and flotation plant have been in operation 20 days, and are stated to be making a high extraction. About 150 tons of concentrate is produced daily. There are 125 men employed, 40 being at the mine. Numerous cottages are being constructed for employees. Six motor-trucks are to be used in transportation of supplies and concentrate.

Los Angeles.—Tonopah & Tidewater Railroad traffic department announces that it will aid in bringing to the attention of manufacturers and capitalists any desirable undeveloped mineral resources along its line. Analysis will be made free of charge, provided samples justify the expense.

Walker.—Klamath River Dredging Co. has started prospecting an extensive area of promising placer ground in this district. It is improving its dredge. Adjacent territory has been taken under option. J. R. Wade is superintendent.

Sutter Creek.—Old Eureka Mining Co.'s statement of September 17, 1917, shows the following expenditure to that date in re-opening this mine:

Item	Cost
Construction and improvement.....	\$71,735
Tools and equipment	3,756
Pumping and shaft repairs.....	117,657
Taxes	1,771
Mine development	3,849
General operating charge	19,415
Purchase of 111 acres adjoining.....	10,211
Total	\$228,394

Cash in California and New York totaled \$41,769; and supplies \$9687. Future plans are to push development in drifts and sink main shaft. As far as sunk, south side of shaft has been stoped, but none on north side for last 150 ft. Vein is mixed with slate and gouge for 5 ft. between walls. Management is highly optimistic as to future.

Winthrop.—The Arnstein syndicate has completed arrangements for diamond-drilling the Bully Hill mine to depth of 1200 ft. Excellent ore has been developed on the 900 and 1000-ft. levels of the Rising Star shaft. Shipments to the Kennett smelter have been increased to 125 tons per day.

COLORADO

Georgetown.—W. J. Chamberlain Ore Co. has decided to close its sampling-works here, also at Breckenridge and Blackhawk. They will be dismantled. Lack of ore and concentrate, and high cost of operation, caused this step. The Idaho Springs sampler will continue to receive ore.

Rich silver-lead ore has been opened in Georgetown adit in Columbia mountain.

Denbigh Mines Co.'s Terrible mine is shipping three cars per week of high-grade silver-lead ore. Thirty-three men are employed.

Hollingsworth Mining Co.'s Smuggler mine continues regular shipments of zinc-lead ore. Development is reported as good.

IDAHO

Adair.—Montana-Idaho Copper Co., which has been driving an adit for two years, reports that it has cut what is considered to be the Monitor vein at 3865 ft. Ore is 10 ft. wide, carrying copper in small quantity. The Richmond vein, 300 ft. farther on, is to be cut by extending the adit, which is in 4275 feet.

Kellogg.—Caledonia Mining Co. pays 3c. per share, equal to \$78,150, on April 5.

Kelton.—Melcher Mining Co. will start its new 100-ton concentrating plant, including flotation, early in April. Mine said to contain large low-grade orebodies. Shipping ore assays 29 oz. silver, 41% lead, and 2.7% copper. Property is 55 miles north of Kelton in Stokes district of southern Idaho, also 24 miles from Delco, nearest railroad point. Pere McIntyre is superintendent.

Kingston.—Hypotheek Mining & Milling Co. has levied an assessment on account of adverse circumstances—local—and price of lead. Indebtedness is \$20,000. Recent development on 900-ft. level has opened 8 ft. of ore, nearly equal to the shoot at 700 ft. Ore is being shipped.

Mullan.—Flynn property, near Morning mine of Federal M. & S. Co., has been sold to Edward Ehrenberg and others of Spokane for over \$500,000. Little development has been done, but prospects are considered extensive.

Federal Mining & Smelting Co.'s quarter ended January 31, 1918, shows a loss of \$193,525, after deducting \$25,757 for depreciation. A year ago there was a profit of \$316,164 in this period.

In suit of Federal M. & S. Co. v. Star Mining Co., for alleged trespass and removal of a large quantity of ore, original suit started and won by Star company in 1917, the Federal company won last week in Federal Court at Wallace.

Salmon.—Northwestern Development Co., of Boise, Idaho, is operating the Ranger copper claims, 12 miles east of Salmon in Lemhi county. New York people worked the property for gold in the 'eighties, but lost 60% in the tailing. They spent \$260,000 in all. Copper was a detriment to treatment at that time. From 1883 to 1917 the mine was full of water, when present company obtained control. By September last unwatering was complete. Examination showed an ore-shoot 320 ft. long, averaging 4 ft. wide, worth \$40 in copper and \$50 to \$75 gold per ton. This shoot had been developed by a shaft 150 ft. deep, ore had been stoped to a depth of 100 ft. from the surface, leaving 50 ft. of shaft in ore with a drift running from the bottom exposing ore mentioned. After examination workings were allowed to fill with water again. A survey was made and a tunnel-site located so as to cut the vein at a depth of 650 ft. Work was immediately started on the Ashland adit, supplies and equipment were stored on the mine, and work has been done all the winter. This 800-ft. adit will serve a double purpose—drainage and transport of ore to the top of a mill to be erected adjacent to property. Dumps contain 10,000 tons of \$10 gold-copper-silver ore. When ore worth \$500,000 is blocked out a concentrating plant will be erected. Hydro-electric power can be developed nearby. Ore appears to be amenable to flotation.

MICHIGAN

Houghton.—Calumet & Hecla plans completion of 10,000-kw. power-plant at its works on Lake Linden. Finish of the new office is the only construction that this company contemplates this year. The new hospital at Calumet will not be erected until after the War.

Calumet & Hecla Mining Co. reports as follows:

Mines	February, lb.	Two months
Ahmeek	2,029,893	4,125,381
Allouez	643,426	1,381,205
Calumet & Hecla	6,137,485	12,248,589
Centennial	204,568	468,001
Isle Royale	1,148,129	2,186,691
La Salle	136,877	287,840
Osceola	1,408,457	2,717,990
Superior	146,070	325,907
White Pine	222,418	475,916

MISSOURI

Joplin.—Production of Missouri-Kansas-Oklahoma region last week was 7393 tons blende, 300 tons calamine, and 1622 tons lead, averaging \$51, \$35, and \$84 per ton, respectively. Total value was \$523,922, making \$5,137,077 for 11 weeks.

MONTANA

Butte.—East Butte Copper Co. produced 2,324,000 lb. in February. About 40% is from custom ore. Flotation plant is treating tailing averaging 1% copper, recovering 0.8%. Dutton mine is contributing 11% ore for smelter. From 1500-ft. level of Pittsmtont mine 5% ore is being extracted. Company proposes to sink a new shaft west of main at the Pittsmtont mine.

Troy.—Snowstorm Mines Consolidated reports that milling started in April 1917, and to end of year 61,647 tons of ore yielded concentrate containing 340 oz. gold, 70,075 oz. silver, and 3,364,439 lb. lead; also 105 oz. gold, 19,905 oz. silver, 536,120 lb. lead, and 1,826,903 lb. zinc. Shipments were valued at \$256,372, plus \$29,740 in transit. Opera-

tions cost \$202,971. After paying all charges, net profit was \$23,349. Cash, supplies, and ore in transit are valued at \$50,873, and equipment at \$633,969. Current liabilities are \$47,601. Leo Greenough is president.

Twin Bridges.—Results in 1917 of mines in the Tobacco Root range of Madison county were the best on record, but the coming season is expected to be better. The B. & H. mine employs 50 men. Mill is closed temporarily, but high-grade ore is being shipped. Investor's company, operating the Lake Shore mine, has a modern cyanide plant in its mill. Crystal Lake company is erecting a mill. Generally the district is busy.

NEVADA

Copper Canyon.—Copper Canyon Mining Co. is shipping 40 to 50 tons of ore daily, employing a caterpillar tractor and four horse-teams to Dillon, the nearest railroad point. Ore of good grade is being drawn from the new 113 and 188 stopes. Preparations have been made to re-open old stopes on the second vein.

Elko.—Standard Oil Shale Co. was re-organized at Salt Lake City on March 17. Samuel Newhouse is president. Capital is \$1,250,000. Property consists of 4000 acres near Elko, and 1000 acres near Levan, Juab county, Utah. To distill oil from the shale a 100-ton plant is to be erected at Elko.

Fernley.—Work is again under way at the Talapoosa mine, 12 miles south-east of Fernley. L. Graefe is in charge and reports that the shaft is to be deepened. Vein has been opened 200 ft., and is from 8 to 15 ft. wide. Silver constitutes 75% of total value. About 20 tons daily of silver-gold flux ore is sent to the Mammoth smelter at Kennett, California. Property was subject to litigation in 1909, and was idle four years. Now under lease to J. F. Gaines and others of Paso Robles, California.

Goodsprings.—Zinc mines closed last fall are being reopened on account of price of spelter being fixed by the Government.

Manhattan.—White Caps mill is treating 115 tons daily of ore from east orebody on 300-ft. level.

Manhattan Consolidated had a sudden inrush of water last week, rising 130 ft. to No. 4 level before pumps got it under control.

National.—Santa Rosa group of seven silver-gold claims has been sold by F. R. O'Leary of National and George H. Pearce, Stockton, California, to J. P. Clough, Duluth, Minnesota. The property is 4 miles north of Paradise Hill, a few miles from National.

Silver Peak.—Nivloc Mining Co. is operating the old Stimler mine 12 miles west of this place. Shaft is down 440 ft., and on 200-ft. level good ore has been opened. Harry Stimler is in charge.

Tonopah.—Development in this district last week revealed nothing of importance, although all work is entirely satisfactory.

Dividend of 7½% will be paid by Tonopah Mining Co. on April 20. This is the 51st regular quarterly distribution, and makes \$14,650,000 to date.

Tonopah Divide shares rose to \$2 last week on strength of 20 ft. of ore at 160 ft. and 50 ft. wide at 270 ft. depth. Ore is said to be of good grade. This mine is in the Gold Mountain district, near Tonopah, where operators are endeavoring to eliminate extralateral rights and have vertical side-lines.

Virginia City.—Union Consolidated pays an extra dividend of 5c. per share on April 1. This is the fifth since February 1.

Verington.—Nevada-Douglas in February made a profit

of \$20,000 from its mines and \$10,000 from the railway. Shipments are 260 tons daily. In the Western Nevada claim a good deal of 2.7 to 5% copper ore has been opened. On 800-ft. level of Ludwig mine a new orebody assays 3 to 15%.

NEW MEXICO

Columbus.—Sierra Rica Mining Co. of Luna county has been incorporated by B. M. Reed, B. Roby, and F. D. Rody, with a capital of \$1,000,000, of which \$2000 is paid up.

OKLAHOMA

Production of all districts last week was 4716 tons blende and 1356 tons lead, valued at \$353,560.

Commerce.—This district's output is growing, following a period of only fair production.

Hockerville.—Choctaw Chief Lead & Zinc Co. has opened ore 15 ft. thick, assaying 8 to 17% blende and lead, and is erecting a mill.

Picher.—Crystal Mining Co. of Oklahoma City is to erect a 250-ton mill at an early date. Ben B. Dancy is president.

Mint Mining Co., in Blue Mound district, has found 15% ore by drilling to depth of 175 to 270 feet.

OREGON

Gold Hill.—Millionaire gold mine, three miles east of this place, closed for a number of years, has been sold by the McKeen National Bank, of Terre Haute, Indiana, to Charles Knight and associates of that city. The new owner has arrived at Gold Hill and taken charge. He reports that much new machinery is in transit to the mine. This mine is on level ground at an elevation of 1730 ft., and is opened by two vertical shafts 400 ft. deep, with several hundred feet of levels opened both ways. There are three parallel veins, which strike east and dip 60°. All contain quartz with pyrite, with some galena and chalcopryite. Country rock consists of dark argillate, with bands of andesitic material. Shafts are well equipped with electrically-driven machinery. Mill includes two Nissen 1500-lb. stamps, with amalgamating plates, crushers, and Standard concentrating tables, which have never operated.

UTAH

By April 1 the following companies will have paid dividends amounting to \$4,468,000:

	Per share	Amount
Utah Consolidated	\$0.50	\$150,000
Utah Copper	2.50	4,061,250
Bingham Mines	0.50	71,500
Silver King Con.	0.10	75,000
Tintic Standard	0.03	35,250
Judge M. & S.	0.12½	60,000
Daly	0.15	15,000
Total		\$4,468,000

Bingham.—U. S. S. R. & M. Co.'s mines in this district produced as follows in 1917: 203,212 tons of ore, 28,063 oz. gold, 826,751 oz. silver, 17,712,924 lb. lead, and 10,175,014 lb. zinc. Gross value was \$3,667,410, and cost of extraction \$2,947,784, leaving \$719,626 net.

Gold Hill.—Deep Creek Investment Co., F. W. Ferriss president, may erect a mill in this district to treat low-grade ore.

Garrison Monster company's lessees have opened rich gold-silver-lead ore.

Park City.—Ore and concentrate shipments last week totaled 2160 tons. A feature was the initial shipment of 240 tons of spelter by the Judge M. & S. Company.

Silver King Consolidated adit is in 5800 ft. Three shifts are advancing 16 ft. daily. Distance to company's Call-

fornia-Comstock property is 8000 ft. farther. This mine is said to show 40,000 tons of ore above 250 feet.

Daly Mining Co. pays 10c. per share on April 1. This is equal to \$15,000 and makes \$3,000,000 to date.

New Quincy Mining Company reports for 1917 that revenue totaled \$17,342, including \$2149 from sale of ore. Expenses were \$17,306, leaving \$36 on hand. Debt at end of year was \$45,626. Superintendent P. P. Harrington states that 6 cars of ore was shipped. Developments appear to be favorable.

Tintic.—Centennial Eureka mine in 1917 yielded 47,175 tons of ore, 7719 oz. gold, 560,910 oz. silver, 117,170 lb. lead, and 1,648,286 lb. copper. Gross value was \$1,082,192, and cost of extraction \$790,921, leaving \$291,271 net.

WASHINGTON

Clewelah.—Northwest Magnesite Co. is to spend \$150,000 in new machinery. R. N. Bishop is in charge. This mine was closed two weeks ago, no reason being given.

United Copper Mining Co. shipped 14 cars of ore during February. Ore from 1250-ft. level averaged \$115 per ton. At that point the vein is 5 ft. wide, with 6 to 18-in. rich streak, remainder assaying 7% copper and 8 oz. silver per ton. Diamond-drilling is to be started soon.

Metaline.—Spokane and Metaline men have a bond and 3-year option for \$85,000 on Diamond R. and Bella May properties from the Spokane Lead Co. Royalties on shipments are to apply on purchase price. Large bodies of zinc ore are said to have been recently uncovered in the Bella May, and also some splendid lead ore in the Diamond R. New company is to be known as Diamond R. Mining Co. and is composed of R. H. Hutchinson, W. H. Crawford, E. S. Campbell, Oscar DeCamp, and T. S. Hutchinson.

Nighthawk.—At this place in Okanogan county, the Bender Metals Milling Co. is constructing a mill, but has no mine. The idea is to treat ore from the Cabin silver-lead mine, Rich Bar, and others in the district. J. W. Douglas is part owner.

Oroville.—A mill is to be erected at the Ivanhoe mine on Palmer lake. A. W. Boyd is superintendent, and W. B. Boucher of Edmonton, Alberta, is largely interested.

Republic.—Last Chance mine of Lone Pine-Surprise Consolidated Mining Co. has been re-opened. Additional boilers have been installed. Production is to be increased to 1000 tons per month. C. P. Robbins is in charge.

CANADA

British Columbia

Anyox.—Granby Consolidated company's copper production in February totaled 3,843,686 lb., of which 3,125,677 lb. came from the Hidden Creek mines. A year ago the total was 2,580,288 pounds.

Nanaimo.—Granby Consolidated is preparing for construction of wharves, coke-ovens, and considerable equipment at its coal mine here.

Trail.—Ore received by Consolidated Mining & Smelting Co. during second week of March amounted to 9602 tons.

Ontario

Cobalt.—First two months of 1918 have been prosperous for local companies. Despite one of the severest winters known to pioneers of northern Ontario, silver production continued uninterrupted. With spring near, and silver prices holding firmly at around \$5c., there are indications that the current year's output will surpass in value any previous yield.

At Trethewey mine, 3 Groch flotation machines have been ordered to treat 150 tons daily of tailing from the 66,000-ton dump.

Flotation plant is to be installed at Peterson Lake mine, to treat 9000 tons of tailing assaying 9 oz. silver per ton. About \$62,000 is estimated to be extracted, against which must be placed cost and operation of plant, about \$15,000.

Nipissing mine during February produced silver valued at \$295,546. The high-grade mill treated 82 tons, and the low-grade mill 5995 tons of ore. Although a short month the yield was well up to average.

La Rose company's Violet mine shows three veins in keewatin formation at depth of 380 ft. This is regarded as of great value to the company.

Kerr Lake in February produced silver valued at \$175,784, of which \$122,640 was profit.

Gowganda.—Mining men of this district recently asked the Minister of Lands and Mines and the Deputy Minister for \$200,000 to construct a road from Elk Lake to Gowganda, about 30 miles. A grant of \$100,000 may be secured. Freight costs up to \$1 per 100 lb.

Kirkland Lake.—Lake Shore company's new mill was started last week.

Porcupine.—Important feature of this district is the steady improvement in labor supply. Wages paid are high, and tend toward higher operating costs, but in return efficiency of employees improves.

CHILE

Chuquicamata.—Chile Copper Co. in January produced 8,358,000 lb. of copper.

Sewell.—Braden Copper Co. produced in February 4,754,000 lb., compared with 6,200,000 lb. in January.

MEXICO

Aguascalientes

Aguascalientes.—American Smelting & Refining Co.'s smelter here was closed last week, 1500 men being out of work. Cause for suspension is said to be an attempt by the State of Aguascalientes to collect \$22,000, plus \$13,200 Federal stamp-tax, alleged to be due the State and Nation in taxes under an article calling for a tax of 0.5% on the product of the plant. At the division office of the A. S. & R. Co. at El Paso, Texas, it was said that the attempt of the State of Aguascalientes to collect the additional tax is unconstitutional, and that the tax would be prohibitive. It was also said that the Mexican government had advised the company not to pay the State tax. Smelter had been operating nearly a year on ores principally from the Santa Francisca and El Orito mines in the Aguas and Tepezala districts, shipping the bullion produced to the East for refining. The A. & S. R. smelters at Monterrey and Matehuala are still operating. The Mexican manager, C. L. Baker, has gone to New York.

Sonora

Chinipas.—Rio Plata mine of H. W. Miller and others, 20 miles from this place in south-western part of the State, is one of the few American-owned properties that passed through the revolution without molestation. New machinery has been erected recently, and the mine is producing considerable silver ore.

Cananea.—Calumet-Sonora Mining Co., whose property is 4 miles from here, is erecting a 500-ton concentrating plant to treat ore from the Catalina mine. Ore is a sulphide, and carries silver, lead, zinc, and copper. Company is now operating a 200-ton plant to which flotation equipment is being added.

El Tigre.—North Tigre mine, adjoining El Tigre mine here, has been leased to New York people represented by F. J. Holmes of Douglas, Arizona. Underground workings amount to 5000 ft. Reserves are estimated as 30,000 tons averaging 24 oz. silver per ton. Shipping ore carries 6% copper and some lead. Mill is of 25-ton capacity and is to be enlarged.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Eugene B. Braden is at New York.

L. S. Austin is at Long Beach, California.

J. M. Callow was in New York last week.

C. R. Wilfley is here from Ouray, Colorado.

F. R. Weeks has returned to New York from Cuba.

Ben. S. Revett has returned from northern California.

A. H. Elftman, of Goldfield, Nevada, is in San Francisco.

George J. Bancroft, of Denver, was in San Francisco this week.

C. F. Tolman Jr. has gone to Arizona on professional business.

D. B. Dowling has been elected president of the Canadian Mining Institute.

E. R. Robinson has joined the 27th Engineers, and is at Camp Meade, Maryland.

C. G. Patterson of the Butters Filter Co. has left Johannesburg and gone to Chile.

N. B. Roper is general manager for the Sociedad Minera Backus y Johnston, in Peru.

T. J. Harwood is now manager of the Schumacher mine in the Porcupine district of Ontario.

H. DeWitt Smith is superintendent of mines for the United Verde Copper Co., at Jerome.

E. H. Hamilton has left Trail, B. C., and is now with the U. S. Smelting Co. at Midvale, Utah.

S. S. Fowler passed through San Francisco on his way from British Columbia to southern California.

John F. Bauchelle and F. M. Wichman have formed a partnership, as mining and metallurgical engineers, at Salt Lake City.

Lewis Searing has sold his interest in the Denver Engineering Works to H. W. Hardinge, of the Hardinge Conical Mill Co., New York.

Edward McSherry, of Boulder, Colorado, has been appointed foreman of the mill of the Molybdenum Products Co., at Climax, near Leadville.

Evander B. Schley succeeds his father, the late Grant B. Schley, as president of the Britannia Copper Mining Co. and other enterprises in British Columbia.

S. S. Fowler, James Anderson, and Ivan De Lashmutt constitute the committee selected to enquire into the fairness of the rates charged by the Trail smelter of the Consolidated Mining & Smelting Company of Canada.

H. H. Nicholson has resigned position of consulting engineer to the Pimco Copper Co., and is examining copper properties in south-western Nevada, with headquarters at Luning.

Henry R. Putnam, who recently returned from China, has been appointed a Captain in the Engineer Reserve Corps and has been assigned for duty at the General Engineer Depot, Washington, D. C.

Edward W. Clark, until recently advisory engineer to ex-Senator W. A. Clark, died at Whittier, California, on March 21. He was born in Wisconsin and went to Montana in 1880. Later he became manager of Clark's reduction works at Butte and opened up the Mayflower mine. In later years he lived at Ophir, in Utah. He was an able mining engineer and played an honorable part in Western mining enterprise.

A number of topographic draftsmen are wanted by the Department Engineer, Santa Fe Bdg., San Francisco, for work in connection with military mapping. Salaries range from \$90 to \$125 per month.

THE METAL MARKET

METAL PRICES

San Francisco, March 26

May.....	74.27	72.61	85.79
June.....	55.04	76.44	85.79

The sudden rise in silver on March 21 was attributed to demand from China and India. The price of 89 1/2 c. does not actually represent the figure paid for the metal in New York, for payment of a premium, resulting from shipments to the Orient, sent the actual market price to 93 1/2 c. The difference in price represents a saving in freight rates and insurance over the Pacific as compared with costs of shipment by the trans-Atlantic route.

Three-cents per ounce added to New York prices gives about the San Francisco quotation for silver.

If the bill before Congress, to authorize the Government to melt and sell over 200,000,000 silver dollars, is passed, it will release 154,700,000 oz. of metal on the market. On March 1, 1918 there were 461,304,736 pieces of silver coin in Treasury vaults.

Apr.....	141.60	114.50	118.00
May.....	80.00	104.00	118.00
June.....	74.70	85.50	118.00

As an illustration of the variance between the Government 'fixed' or 'arbitrary purchase' prices of a number of commodities the following comparison will be found of interest. The first price column shows the quotation recognized by the Government, the second column gives the actual transaction prices in the New York markets within the past fortnight:

	Government prices	Market prices
Ammonia aqua 28°	8.4	10 1/2
Arsenic	4	8
Acetate of lime	18	38
Glauber's acetate	10	20
Liquid chlorine	37 1/2	37 1/2
Bleaching powder	38	53 to 57
Caustic soda	\$1.50	\$45 to \$50
Phenol		\$5 to \$7
Sulphuric acid, 66° per ton		\$24
Toluol, per gallon		\$5.50

The first is a man factor's price, the second a resale spot offering. The general traders in the trade, however, is to bring the Government and the market quotations into a more reasonable relationship by the elimination of the high 'profit-making' figure even though supplies of the commodity may be small with no assured prospect of immediate relief through surplus production above Federal requirements.—Oil, Paint and Drug Reporter.

Eastern Metal Market

New York, March 20.

The entire metal market is inactive, the dullness having spread to the tin market.

Copper is without new development or feature.

Tin is at a standstill, even for future shipment, with spot metal nominal and unavailable in wholesale lots.

Lead is less active than a week ago and is easier, with quotations unchanged.

Tin continues to weaken, if anything, and is lifeless.

Antimony is quiet and unchanged.

The conference between steel-makers and the War Industries Board is being held in Washington today, and manufacturers have entered it with the knowledge that they will be asked to make reductions on some products, particularly on pig-iron. Foundry-iron makers oppose a lower price, and a compromise may be effected by reducing basic iron \$1 per ton, that is, to \$32, and bessemer iron, which is 10% higher, from \$36.30 to \$35.20. Scrap prices are also likely to be revised, since some grades are already under the Government price. No general revision of existing prices for rolled products is looked for, and steel men contend that the uncertainties of the situation, which are already affecting the demand, should be removed by making the new prices effective for at least six months. Steel output, with some companies, has made a considerable advance in the past week, the Steel Corporation plants evidently coming closer to normal capacity than most of the independent producers.

COPPER

The market is devoid of interest and practically bare of news. The representative of a large copper dealer here said yesterday to your representative that there is no scarcity of copper nor is there an over-supply. He said that there is just enough to meet present needs. While output is better and railroad conditions improved, consumption is tremendous both by the Government and by the Allies. Domestic consumers, not having Government contracts, are not receiving supplies of copper as fast as needed, otherwise deliveries are more satisfactory than formerly. It is claimed that certain consumers, who usually buy metal in jobbing lots from jobbers, are now resorting to scrap-copper, which they can purchase for less than the fixed price of 24.67½c. per lb. that applies to ingot-copper. This is easily feasible when the proper grade can be assured. There is less agitation respecting a higher price for copper. The matter has by no means been forgotten, but it is now recognized that much may happen in the next nine or ten weeks to change conditions which were admittedly bad for low-cost operation in January and February. The present price of 23.50c. per lb. for carload and larger lots is effective until June 1.

TIN

After several weeks of marked activity in dealings in tin for future shipment, the market has come to a complete standstill. The reason is not apparent. In the last 10 days a conservative estimate has placed the transactions in tin for that period as not exceeding 400 tons—and this may be liberal. It was all futures, of course, spot metal, both Banca and Straits, being unobtainable in large lots. Tin is tin now, and buyers will take anything they can get when they must have it. A 5-ton lot of Chinese tin sold at 83c. here a few days ago for spot delivery, and a parcel of 25 tons of double refund Lamb & Flagg metal brought 86c.,

almost as soon as offered. Cables continue to be abnormally delayed, greatly retarding dealings. Arrivals to March 18, inclusive, were 1202 tons, with 6300 tons reported afloat. The London market has not changed much in the week. Yesterday the quotation there for spot Straits was £321 10s., or £1 under last week.

LEAD

There has been very little change in the past week. The tone is decidedly easier but quotations are unchanged in the outside market at 7.25c., New York, and 7.10c., St. Louis. The American Smelting & Refining Co. continues to quote 7.25c., New York. The market is entirely a drifting one, with no features of interest. Free offerings have been a little more numerous, but this has not been a factor. Arrivals from the West are better, though some cars are still weeks behind schedule. The easier tone is due almost entirely to the better weather conditions. Buyers are much scarcer and the spot market is lower. This position can be bought as low as 7.37½c., New York, though one dealer says he has sold spot lead at 7.75c. in the last few days. The American Smelting & Refining Co. has closed its smelter at Aguascalientes, Mexico, because of taxes imposed by the Government, it is said. This is covered in The Mining Summary of this issue.

ZINC

Despite predictions some time ago that the market could not go any lower, the past two or three weeks has witnessed a gradual weakening. Since our last letter a week ago the situation has not grown better, and the market for prime Western is even weaker. The quotation for early delivery is unchanged at 7.50c., St. Louis, or 7.75c., New York, that of most of the large interests, though some are quoting 7.37½c., St. Louis, or 7.62½c., New York. Sales are not of any consequence, being limited to small lots here and there. It is market opinion that the production of prime Western must decline still further to impart any strength to the market, for it is believed by many to be impossible to get more than a new dollar for an old one now. Grade A is officially pegged at 12c. per lb., and sheet zinc at 15c. Exports in January were 13,025 tons, as compared with a monthly average in 1917 of 16,024 tons. This is a decline of about 20%.

ANTIMONY

Outside of Government purchases there is very little doing and these transactions are not made public. One dealer estimates that the Government purchases have probably been made at an average of 13c. per lb. Sales of small amounts are reported, but the market is generally quiet at 13.25c. per lb., New York, duty paid, for Chinese and Japanese grades for prompt and early delivery. Imports of antimony were nearly 70% larger in 1917 than they were in 1916.

ALUMINUM

For 50-ton lots and over of No. 1 virgin aluminum, 98 to 99% pure, the Government price of 32c. per lb. rules. In the last week differentials have been established, among which may be mentioned 22.10c. per lb. for 15-ton lots, and 22.20c. per lb. for 1-ton lots. Scrap prices have not been announced. The price of aluminum in France has been advanced from 4 francs (32.7c. per lb.) to 6.40 francs, or 50.9c. per lb., according to the French paper 'Echo des Mines.'

Company Reports

EDNA MAY GOLD MINING CO.

Property: gold mine at Westonla, Western Australia; one of the few new producers in the Commonwealth.

Operating Official: M. T. Williams, general manager.

Financial Statement: during half-year ended October 31, 1917, revenue was £62,943. Six dividends, one of 72c. and five of 48c., absorbing £27,520, were paid. Balance forward was £59,354.

Development: the 480-ft. level is being opened, and reserves to that depth are 50,393 tons, assaying \$15.44 per ton. Water pumped is 40,000 gal. per hour. Development cost \$2.24 per ton.

Production: in the 6 months under review, the mill treated 18,092 tons of \$15.18 ore. Of the gold, 90.17% was extracted by amalgamation and 7.89% by cyanidation. To date there has been treated 140,064 tons, yielding gold worth £580,772 (\$2,900,000), an average of \$19.90 per ton.

Costs: for period were \$5.64 per ton.

OSCEOLA CONSOLIDATED MINING CO.

Property: copper mine in Michigan, controlled by Calumet & Hecla Mining Company.

Operating Officials: F. H. Haller, superintendent; A. L. Burgan, mill superintendent; James Rowe, mine superintendent; C. D. Hohl, engineer.

Financial Statement: receipts from copper delivered in 1917 were \$3,453,758. Gross profit was \$1,777,625, less \$105,159 for income-tax and \$496,935 for excess profits tax, leaving \$1,175,532 net. Balance of current assets at beginning of year was \$2,677,547, and at end \$2,410,190.

Dividends: in 1917 amounted to \$1,346,100, making \$16,602,575 to date.

Development: 6309 ft. was done during the year. No. 5 Osceola shaft is 4667 ft. deep, and No. 6, 4734 ft. That part of the Osceola mine above No. 46 level and nearest extreme south was most productive and profitable. In North Kearsarge mine, 3 storage-battery locomotives and 5-ton ore-cars were ordered for No. 4 shaft. The South Kearsarge mine made a substantial profit.

Production: past four years show the following results:

	1917	1916	1915	1914
Ore hoisted, tons...	1,245,757	1,295,836	1,380,255	1,136,118
Sorted out, per cent	0.638	0.861	1.359	2.436
Ore milled, tons...	1,237,805	1,284,681	1,361,089	1,108,447
Copper, pounds...	16,084,958	19,586,501	19,731,472	14,970,737
Average per ton, lb.	13.0	15.2	14.5	13.5
Cost per ton.....	\$1.63	\$1.36	\$1.18	\$1.29

HOMESTAKE MINING CO.

Property: one of the largest gold mines in the world, fully equipped with hydro-electric installations, mining plant, 1020 stamps, sand and slime cyanidation plants, foundry, etc., all at or near Lead, South Dakota.

Operating Officials: superintendent, B. C. Yates; metallurgist, W. J. Sharwood; consulting metallurgists, C. W. Merrill and A. J. Clark.

Financial Statement: for year 1917 receipts from bullion were \$6,619,574, from wolframite, \$226,535, and from sundries, \$30,865, a total of \$6,876,974. Disbursements totaled \$4,868,145. This left an operating profit of \$2,008,829. Balance forward from 1916 was \$949,934, and that carried forward to 1918 is \$1,189,403. General supplies increased from \$383,635 to \$553,240. Liberty Bonds amount to \$210,000.

Dividends: paid last year amounted to \$1,959,048, making over \$40,000,000 to date.

Development: total new openings covered 19,320 ft. Estimates of broken ore show 1,919,177 tons. Blocked out there is ore for many years extraction. A new ventilating system for lower levels is well under way. Electrically-driven fans form part of equipment. The new Nordberg hoist and skips can easily supply the Homestake mills. At 800, 1100, and 1550-ft. levels are loading-pockets. The wolfram deposits should be able to keep the small mill supplied for another year. Every department is in first-class condition, according to Richard Blackstone, previous superintendent, who resigned late in 1917 after 39 years service.

Production: mills and cyanide plants treated 1,677,623 tons of ore averaging \$3.9458 per ton, yielding gold valued at \$6,619,574.

Costs: although dressing of wolframite is included, costs may be summarized as under:

Department	Per ton	Department	Per ton
Mining	\$1.35	Cyaniding	0.20
Development	0.05	New electric plants	0.26
Shaft (7) operation	0.28	Taxes	0.18
Tramway	0.01	Sundries	0.23
Milling (6)	0.29		
Regrinding	0.02	Total	\$3.90

Sundry items include freight on bullion, Ellison hoist, steam and coal line, property purchase, aid fund, benefices, hospital, and recreation hall operation, office, legal, etc.

YUKON GOLD CO.

Properties: dredging ground on the American, Butte, Feather, Trinity, and Yuha rivers in California; dredging ground on Prichard creek, Idaho; dredging ground at Dawson, Yukon; and at Ilditarod and Ruby, Alaska; hydraulic property at Dawson, with 70-mile ditch, power-plant, etc.; and gold mine at Jarbidge, Nevada.

Operating Officials: C. H. Munro, acting general manager; E. E. McCarthy, manager at Dawson; H. C. Perring, manager of Pacific operations; C. E. Moran, secretary.

Financial Statement: 1917 income from gold, etc., totaled \$3,965,231. Operations cost \$2,226,992, plus \$365,094 for royalties, interest, and general expense. Net income was therefore \$1,373,146.

Dividends: \$1,050,000 was distributed during the year.

Development: 7½-cu. ft. dredge on American river finished its work, and was re-erected on North Fork, to resume early in May 1918. Boat on Trinity started on December 9. Murray 7½-cu. ft. dredge in Idaho started on December 4 in a new field, but is quite satisfactory. Ground proved contains 10,600,000 cu. yd., averaging 14.4c. per yard. Seven boats worked at Dawson. This, the eleventh season, lasted 151 days. As two completed their work, only five will operate in 1918. Dredge at Ruby worked 153 days, completed its ground, and has been dismantled. Ilditarod dredge worked 192 days. Season for hydraulicking was generally favorable, but was not ideal for thawing gravel banks. At Jarbidge, 100-ton mill at Elko mine, also 75-mile transmission-line, were completed and are ready for operation in March 1918. Starlight mine nearby was acquired. It contains 9800 tons of ore worth \$212,000 gross value.

Production:

Operations by	Cubic yards	Per yard	Cost	Profit
California dredges	0.161,941	\$0.0810	\$0.0371	\$289,155
Dawson dredges	4,583,326	0.3787	0.2581	553,099
Dawson hydraulics	2,143,444	0.2147	0.1180	207,709
Ilditarod dredge	871,015	0.9150	0.1810	377,834
Ruby dredge	264,132	1.1710	0.5320	169,415
Total	14,025,888			\$1,597,212

Latest estimates indicate that earnings from present properties will be insufficient to meet notes aggregating \$5,000,000, held by Yukon-Alaska Trust, also to continue present dividends; therefore disbursements are to be reduced for the time being.

Mining Decisions

Coal Lease—Subjacent Support

In a suit by a lessor of coal lands against his lessee for damages resulting from the subsidence and caving in of the surface caused by lessee's mining operations, held, that the lessor did not waive his right to subjacent support by executing a coal-mining lease which did not expressly contain such a waiver.

Walsh v. Kansas Fuel Co. (Kansas), 169 Pacific, 219. December 8, 1917.

Oil and Gas Lease—Royalties

Under an oil and gas lease entitling the lessor to certain royalties from oil-wells brought-in and certain further royalties from gas-wells brought-in, held, that where the lessee brought-in a well which produced both oil and gas in marketable quantities and under marketable conditions, he must pay both royalties on the one well.

Prichard v. Freeland Oil Co. (West Virginia), 93 South-Eastern, 371.

Mining Claim—Character of Ground—Adjudications

A plaintiff seeking an injunction to restrain trespass, based his title on an alleged mining location, made according to law, but subsequently included within the boundaries of a National Forest Reserve. Defendant interposed a plea of former adjudication by the Secretary of the Interior of the non-mineral character of the land given at a former period in denying plaintiff's application for a mineral patent to his claim, and claimed that plaintiff's location was therefore void because of lack of discovery. Held, judgment for defendant. Decisions of the Land Department have the effect of final adjudications as to matters properly within its jurisdiction, such as determination of the character of the land in patent proceedings, and will be so recognized by the Courts. A later judgment establishing plaintiff's title as against other parties will not avail plaintiff in this case, because the Government was not a party to that suit.

Cameron v. Bass (Arizona), 168 Pacific, 645. November 8, 1917.

Mining Claims—Location Requirements—Seniority

Failure of mining locators to comply with the State statutes relating to the recordation of location notices within 20 days after the discovery, where the State law does not expressly provide for a forfeiture upon such failure, does not invalidate the location. The defects are cured by subsequent issuance of patent on the theory that it amounts to an adjudication of sufficient compliance with location formalities. They are also cured by subsequent amendments to the Montana codes, validating prior locations which conform with the amended law. Priority of a senior location is not lost by failure to adverse the application for patent of a junior location where no conflict on the surface is shown by the survey for patent or notice of application. A quit-claim deed covering an undivided interest in the Black Rock claim is not a conveyance by metes and bounds and does not estop the grantor from asserting subsequent claims to extralateral segments of veins apexing on other claims, where the segments underlie the Black Rock surface. Findings of the trial court as to continuity of veins and ownership of points of intersection held supported by sufficient evidence.

Butte & Superior Copper Co. (now B. & S. Mining Co.) v. Clark-Montana Realty Co. (Montana), Decision U. S. Circuit Court of Appeals, February 18, 1918. (Not yet reported).

Book Review

TREATISE ON APPLIED ANALYTICAL CHEMISTRY. By Vittorio Villavecchia and others. Translated from Italian by T. H. Pope. Vol. I. Pp. 475, ill., index. P. Blakiston's Son & Co., Philadelphia, 1918. For sale by MINING AND SCIENTIFIC PRESS. Price, \$6.

Customs departments in most countries maintain laboratories in which products imported and exported are tested for valuation and standard purposes. The variety of analyses made covers a wide range, as will be seen by studying this work containing methods and standards for analysis of the principal industrial and food products. The author is director of chemical laboratories of the Italian Customs, and arranged the methods in collaboration with nine other chemists. Adulterations and impurities are found in most finished materials, and their determination constitutes a branch of chemistry worthy of cultivation by commercial, hygienic, and technical chemists, also by government inspectors. Volume I, the work under review deals with analyses of potable waters, acids, and chemical compounds, fertilizers, cement materials, metals and alloys, fuels, mineral oils, and fatty substances. Mine and smelter metallurgists will find much of value in this book. We like the concise arrangement of methods, and while it cannot be classed as elementary, yet the contents should be followed easily by students. Probably the translator is responsible for much of this desired brevity. As a practical work we commend it to chemists.

The Annual Chemical Directory of the United States for 1918 is announced by the Williams & Wilkins Co. of Baltimore. It gives names and addresses of all manufacturers of acids, alkalies, colors, dyes, drugs, explosives, synthetic products, chemical and metallurgical apparatus, machinery and supplies, professional firms, laboratories, Federal and State officials having charge of such industries, societies, and technical journals. The price is \$5.

LOANS AND TAXES

The issue of \$500,000,000 of United States Treasury certificates, subscription to which closed March 5, was over-subscribed, the subscription in every district, except one, exceeding the quota assigned it. The banks of the country in the past two Liberty Loan campaigns, and in the purchase of Treasury certificates issued before the loans, responded to the demands of the country with inspiring loyalty and liberality. The faith they show in the Government finances and the patriotic response they give to the calls of the Treasury are certain indications that their co-operation and assistance will help to insure the success of the Third Liberty Loan. Subscriptions for this loan open on April 6. In our New York letter of this issue the financial situation is discussed.

In comparison with the tax levied on incomes in England, American taxes are moderate. In England the tax on incomes of \$1000 is 4½%; in America nothing. In England the tax on incomes of \$1500 is 6½%; in America nothing for married men or heads of families, and 2% on \$500 for an unmarried man. In England the tax on an income of \$2000 is 7½%; in America nothing for a married man or head of a family, and 2% on \$1000 for unmarried men. The British income-tax rate also increases more rapidly with the growth of the income than ours, a \$3000 income being taxed 14%, \$5000 16%, \$10,000 20%, and \$15,000 25%, while our corresponding taxes for married men are respectively two-thirds of 1%, 1½%, 3½%, and 5%, and only slightly more for the unmarried, due to the smaller amount exempted, the rate being the same.

EDITORIAL

SIR DOUGLAS HAIG responded simply and sincerely to the President's message of goodwill and sympathy. "One and all," he said, "believe in the justice of our cause and are determined to fight without counting the cost until the freedom of mankind is safe." Is not that the belief of us all and shall we not do our utmost to achieve the purpose for which our soldiers are fighting so unflinchingly?

TODAY is the first anniversary of our declaration of war against the enemy of civilization. Much has been left undone and much has been inadequately done for the waging of war, yet the accomplishment of the last twelve months by a peace-loving democrat, and therefore wholly unprepared, people has been magnificent. Most of all do we rejoice that our own soldiers are at the front during the great battle now in progress. They are the advance guard of an army that, please God, shall teach the Prussian to beware of free men when they are roused to fight for safety and self-respect.

OUR friend Mr. W. J. Sharwood, metallurgist to the Homestake Mining Company, contributes sundry interesting notes on the loss of quicksilver in mills treating gold ores. The study of the subject should lead to economy and efficiency.

IN this issue we publish another useful technical study by Mr. Walter S. Weeks, Associate Professor of Mining in the University of California. The testing of air-compressors is an important matter and it is one not generally understood by the managers of mines. We feel sure that the chart for the nozzle-discharge, more particularly, will be of immediate practical service.

THE article on the methods of recovering quicksilver from its ores, published in another part of this issue, will awaken keen interest in the bulletin on that subject, prepared by Mr. W. W. Bradley and soon to be published by the California State Mining Bureau. Mr. Bradley has confirmed the observations of other experimenters upon the feasibility of leaching low-grade cinabar ore with sodium-sulphide solution. Good recovery is obtainable by this method from ores containing no more than 0.3% metallic mercury. At present prices this

would appear to offer attractive opportunities. The obstacle lies chiefly in the cost of fine grinding, but the process yields recoveries in excess of 80%, so that the margin at the present time is ample.

CONDITIONS created by the War have indicated the need for a new executive department, representing the mining industry, in the Federal administration. We note that the leaders of the American Mining Congress are ventilating the subject and it is fitting that they should do so, for to the Mining Congress we owe the establishment of the U. S. Bureau of Mines. The lack of a Cabinet officer at the head of a Department of Mines has contributed to the confusion and ineptitude that have marked the well-intentioned efforts to mobilize our mineral resources for warfare. That the coal industry should have been placed in the hands of a college president and the buying of metals in the hands of a speculative broker are two of the consequences of official indirection. We shall be glad to support the Mining Congress in its campaign for the creation of an executive officer at Washington to represent the other of the two great productive industries of our country.

AFTER due deliberation between representatives of Mexico and our ambassador, Mr. Henry P. Fletcher, a reciprocity treaty was drafted in February, having in view the more advantageous co-operation of the two governments concerned. It did not give to Mexico all the privileges while saddling us with all the obligations, since the object of reciprocity is mutual advantage. It was to be assumed that the Mexican diplomatic agents would not exceed their authority when they occupied the time of our representatives in these negotiations, but Carranza has declined to ratify the treaty. It is time that a firm attitude were taken by the authorities at Washington to terminate the diplomatic trifling that has nullified all our efforts at kindly neighborliness ever since Carranza came into power. The acts of his government continue persistently antagonistic, serving to strengthen the conviction that they are inspired by hostile advisers. The new regulations affecting the oil-producers are onerous in the extreme, the American Smelting & Refining Company has been compelled to close its smelter at Aguascalientes because of oppressive taxation, and a German raider was

outfitted the other day at a Mexican port, which would have been utterly impossible if the local authorities had exercised proper vigilance. The last term of diplomacy is mandatory, and it is time that we protect ourselves against the machinations of the Teuton in Mexico by using plain language that admits of no misunderstanding.

DECISION of the Court of Appeals in the flotation suit of Minerals Separation v. Butte & Superior is expected in May. It is impossible to predict the result, because, among other reasons, the judges sitting in this case are not those that sat in the Hyde case. The decision apparently must turn on the question of the part played by the mineral oil added in excess of the so-called critical proportion of vegetal oil, namely, is the mineral oil inert and useless or does it contribute to the metallurgic result? Again, did the Supreme Court's decision in the Hyde case, confining the patent to the 'critical' proportion of oil, mean that the use of more than 0.5% of oil did not infringe, this 0.5% being taken as answering the Court's limitation to "the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions' 'amounting to a fraction of 1% on the ore'." Should the Appellate Court reverse the District Court it is likely that an appeal to the Supreme Court will be granted; should it sustain the District Court, an appeal may be refused. That would mean that the opponents of Minerals Separation would have to start a new litigation, and, it is to be hoped, abandon the defensive.

NEED of ships for direct service to Europe and need of imported minerals are constantly being balanced against each other by the committeemen at Washington. Recently the shipment of manganese ore to this country was restricted, and the importation of pyrite also is coming under the ban. The latest mineral to receive consideration has been chrome. A meeting was held at Washington between the Raw Materials division of the War Industries Board, represented by Mr. Pope Yeatman, the Shipping Board with Mr. J. E. Spurr as spokesman, and a large number of manufacturers and consumers of chrome ore. Mr. Samuel H. Dolbear was summoned from San Francisco to attend the conference. The two chief objects are to stimulate production, and to decrease consumption. The ability of the conference to plan effective measures seems to have been limited by the action of the War Industries Board undertaken without advice from those summoned to consider the question, and even antedating their meeting, whereby a single manufacturer was authorized to act as preferred purchasing agent with the privilege of increasing the price, which was deliberately raised from about 85 cents to a minimum of \$1.25 per unit. The price was not fixed, and as a result quotations in the open market almost immediately advanced to \$2, with a steady upward tendency. The effect is to encourage hoarding and profiteering. This is another example of the undemocratic procedure

of the persons that control our war industry. It is time that President Wilson made his great influence felt in suppressing the evil of favoritism that destroys the confidence of the great mass of the plain people.

THE Tennessee Copper & Chemical Company has at last reached an agreement with the International Agricultural Corporation for a revision of the old contract under which it disposed of its by-product, sulphuric acid. It will be recalled that shortly after the Tennessee Copper company had completed its sulphuric-acid plant as a means of escape from the devil of agricultural protest against smelter-fume, it fell into the deep sea of a glutted market. So depressed was the sulphuric-acid business at the time that the Tennessee concern, to extend the simile, in order to save itself from drowning, was willing to climb upon the perilous raft of a contract that pledged its entire output of acid for a long term of years at the low price of \$4.81 per ton. When the demand for war munitions commenced in 1915, concurrently with a general elevation in prices of labor and commodities, whatever advantage the contract might have possessed previously, quite disappeared. The quotations on acid meanwhile were advancing to unheard of levels. So urgent did the demand become toward the end of 1915 that Eastern firms even bought acid in San Francisco at about \$100 per ton and shipped it to Atlantic seaboard points. The International Agricultural Corporation, apart from utilizing acid in its fertilizer business, acted as a broker, re-selling the acid at enormous prices, and having no further outlay than that involved in negotiating sales and transmitting billing instructions to the Tennessee Copper company. The logical escape from the difficulty appeared to be through an increase in the production. Thus the copper company could take advantage of the favorable market, at least for any surplus over the output of the old works. Having made plans for an extension of plant, a message was sent to the International Agricultural Corporation announcing the intention to enlarge the works, but expressing the conviction that no larger deliveries could be anticipated under the contract. The ink was hardly dry on the telegram before an official of the Agricultural Corporation demanded the entire present and future production of sulphuric acid made by the Tennessee company within the contract limits. It was a case of claiming the pound of flesh that drew the condemnation of all men upon the Merchant of Venice and that draws it still upon his imitators. It is pleasing to note, however, that the International Agricultural Corporation has been unwilling to play Shylock to the bitter end, and has made some concessions to the principle of equity. A small advance over the old rate is now agreed upon, and increased prices are allowed for the product in excess of 225,000 tons per annum. It is unofficially stated, but on good authority, that \$10 per ton will be paid for the output between 225,000 and 300,000 tons. As a result of the settlement of this dispute, the copper company will expend about \$1,000,000 on the enlargement of its plant.

Americanization

In this issue we publish an article that touches upon economic conditions in Arizona and refers incidentally to the heterogeneous character of the elements constituting the labor supply of the copper mines. It has seemed to the author of the article, as to other thoughtful observers, that the existence of a large foreign population in the body politic of the United States is a peril to this democracy. It is high time for every good citizen, notably the members of the mining profession, to realize that the making of a nation out of this industrial population depends upon the assimilation of many unlike elements of alien origin. Until the process of assimilation is reasonably complete the United States, as a nation, will be subject to chronic attacks of political dyspepsia. The census of 1910 showed that 37% of our people were born in Europe or born of European parents, and if to these we add those of negro blood, we see that half of the population was, and is, 'foreign' in the true meaning of that word. We have been told that this is a great melting-pot for the political reduction of unlike elements, but is it not more nearly a mixing-pot in which fusion is lacking? Fusion results from heat, and the rapidity of the process depends largely upon the presence of a minimum of refractory matter. Do we exclude such refractory human material? On the contrary, is not the lid of the crucible kept lifted so that anarchistic Russian-German Jews like Leon Trotzky, alias Braunstein, can come and go as they please? Do not the Emma Goldmans and Max Berkman of Europe find a free entrance? Was not Maxim Gorky petted and Rabindranath Tagore lionized? Such material would retard fusion even at a generous heat of nationalization; but the temperature is kept low, because those in authority recognize the existence of elements so highly combustible that careful treatment is required to safeguard political equilibrium. When the European war started we were told to be neutral, that is, to remain cold to the great conflict on the other side. The foreign elements were asked not to take sides for fear of domestic dissension. The temperature was kept so low that the fusion of these European fragments of nationality became impossible; on the contrary, some of those that had undergone preliminary agglomeration tended to resume their separateness. That did not last long, thank heaven; the United States arrayed herself on the side of human liberty, and the temperature in the mixing-pot rose rapidly, so rapidly that a new process of fusion began, with the promise of melting most of the refractory elements and producing good clean metal that would alloy readily with the best of the products produced by the furnaces of the Civil War and the Revolution. The War is fated to be a great Americanizer, and we thank the Kaiser for that at least! But much more must be done if the process of Americanization is to be expedited. It is surprising to hear of men being drafted into the Army that cannot speak English; they, however, will learn the language quickly

enough among their new comrades, and much more than the language. Any man, whatever his origin, that fights for the United States will return from the War an American indeed. What can we do for the millions that will not obtain the benefit of such an intensive education? In the first place, any engineer that has lived abroad can testify that to understand the people of the country in which one lives, to sympathize with them intelligently and to become a part of them, it is necessary to know their language and to read their daily papers. Difference of language is the first and most obvious barrier to acquaintance and mutual understanding. The alien that does not speak the language of this country cannot understand its political ideals nor can our people obtain the benefit of the knowledge, ideas, or inspiration that he may bring as the expression of the culture from which he originated. The herding of foreigners in separate settlements and the maintenance of their national prejudices by means of newspapers printed in their own languages are among the factors making for social isolation. There should be some means of facilitating the acquisition of English by foreigners, and, it must be confessed, it would be well if more of our people would take the trouble to learn at least one foreign language thoroughly. A simple way of accomplishing both purposes would be to pass a law compelling all foreign-language papers to print an English translation in parallel column. This would serve in the first place as a tax on the foreign-language paper, which is so powerful a deterrent to Americanization, and, in the second place, it would promote the learning of English by the immigrant and his children. Next, we need a conscious and organized effort to hasten the process of assimilation. The Fourth of July last year was observed in many localities as a day for Americanization. It is an excellent idea and honors the event it celebrates, as compared with the chemical and verbal pyrotechnics heretofore flourished by small and big boys on this national holiday. We understand that Mr. George Creel's publicity bureau at Washington includes a department for reaching the foreign-born, "to stimulate their interest in American affairs, to make them realize the motives that led the United States to enter the War, and to enlist their enthusiastic co-operation." If Mr. Creel does that we shall forgive him some of his blunders; he will have done something worth while. The fact must be recognized that not only are many of these foreigners ignorant of American ideas but the more intelligent among them have ideas antagonistic to the orderly state of living upon which this republican democracy of ours is predicated. To teach them our language, to make friends with them, is not only a fraternal act, it is one of self preservation, the conversion of an anti social enemy into a sociable citizen. That is why we like the idea of that Y. M. C. A. building at Miami. Our mining companies depend for their supply of labor largely upon the foreign-born, and if those in authority, whether directors or managers, realize not only their own interest but also their duties as good

Americans they will do as much as they can to promote the rapid assimilation of these undigested chunks of alien race and foreign nationality. The mining engineer can help by showing a sympathetic interest in the operation; he could help greatly by learning the language of some of these foreigners—for example, Finnish in Michigan, Spanish in Arizona—so as to understand and be understood, thereby inciting the foreigner in turn to acquire the language of this country, and thus to become comfortable in it, not as a mere alien laborer, eager to make a little money and return to his native land, but as a willing resident, with the makings of a good citizen. This democracy cannot live healthily so long as it contains a large proportion of individuals ignorant of its traditions and unresponsive to its ideals. The American is not indigenous to this soil. This people is peculiar in being wholly of immigrant origin. Americanization is synonymous with nation-making. The fusion of the unlike elements is essential to the production of the true metal—that metal which found its best expression in Abraham Lincoln.

The Finance of War

There is an economics of war as well as of peace, and while one differs from the other materially, it must be noted that both war and peace are phases of international commerce. War is the rude disentangler of the Gordian knot of economic error, severing by a blow of the sword the hopeless maze produced through unscientific competition. Not many months ago, thousands of good and honorable men, bankers, captains of industry, professors of economics and history, doctors of divinity, philanthropists, were telling us solemnly that war was an anachronism, an impossibility. Those words echo now like a mockery, for we know that they not only sprung from the delusions of our warm-hearted peace-loving people, but that they formed a part of the propaganda instigated by Germany to lull us to sleep while she made ready to attack us unawares. These same people offered us their wise assurance that war could no longer be undertaken because, to seek no other reasons, the bankers would not finance it. Now it so happens that finance has developed into such a gigantic, tangled, mysterious, tropical growth that the plain man is no more able to contradict the expert financier than he is the returned traveler who brings marvellous tales of the wilderness of Borneo or the river of Doubt. Accordingly it was written down on the tablets that the banker would not permit war.

That theory has now proved to be not the torch of progress in the hand of Liberty, but a will-o-the-wisp in the financial swamp. We have seen the nations command their bankers, and receive loyal obedience; we have witnessed the demand upon the citizens for service and the fruits of service, to provide means for the struggle, and it has been given. Nevertheless the alien enemy in our midst manages now and then to play on the old discredited chord, telling us that Germany must soon collapse because she has exhausted her resources for financ-

ing the War. Always some internal difficulty is announced as a reason for expecting a sudden change in the attitude of the Prussian militarists. Always do their supporters find willing pens to promulgate the subtle poison of a Germany on the eve of a cataclysm that will bring her humbled and repentant as a suppliant for a democratic peace. This is part of the psychologic program of our antagonists to relax our nerves and muscles so as to impair our efforts to subdue the Huns in the one and only possible way—by force of arms. We are even told that there is a limit to our own ability to finance war.

Let us strip away the encumbering details of the financial system and get down to the elemental facts. There is a final authority, even in a republic. That authority is the will of the people expressed by Congress. That is the supreme government, the sovereign power. It is created to guard and help the people collectively and individually. It has rights in and above all that you call yours and all that you produce; it also has rights in and over you as a person, a fact that every drafted soldier keenly and fully understands. The thing that sustains this war is not the dollars you pay as taxes, nor the dollars you invest in bonds; it is the output of farm and mine, and personal service in manufacturing and transportation. The dollars are only tokens of service performed but still remaining unpaid in the real materials that constitute wealth. You have not been paid when you receive dollars; it is when you have received wheat and milk and clothing and automobiles that society pays you for the services you have rendered. Your payment in money is credit, a promise to deliver something useful because you first have delivered something useful to your fellows. When you buy bonds you are diverting to your Government stored-up potentialities for commanding an exchange of others' services for past services of your own. It is a gracious and grateful response to the needs of your fellow nationals in an hour of danger; but if you do not respond in that manner, then the Government in its sovereign right as the collective voice and agent of the people will order delivery of the material fruits of the earth and of your service in producing them, in order to carry out its obligation to protect you and your fellows. That rude imperious method, however, will not be necessitated with liberty-loving Americans. It will now be evident that the sinews of war are not the money represented by the bonds, but rather are they the fields of wheat and corn and cotton, the mines of lead and copper, of manganese and tungsten, and the skilled hands and trained intellects of the American people everywhere. These will not soon be exhausted, and with these the War can proceed to final victory. At bottom, the financing of the War reduces to those simple terms, and the Kaiser's agents cannot obscure so plain an issue. It is food, metals, and service that gives us the strength to resist subjection to the will of the Hun. Meanwhile, we must pledge those needful things for the future, by drawing on our stored-up credit to purchase bonds, thus in turn pledging the coming generations as their sponsors in baptism into the freedom of a worldwide democracy.

DISCUSSION

Riffles

The Editor:

Sir—In your issue of February 16 I note a sketch of a rifle recommended by J. W. Dunham. In my opinion, Fig. 2 would work better if reversed. After a number of experiments I found the rifle shown in the accompanying cut to be most satisfactory. The riffling or 'boiling' action of the water is promoted by using a rifle with chamfered top and inclined down-stream. With this form I get nearly all the placer gold in the first six feet, and perhaps two-thirds or even three-quarters of this is caught in the first two feet with careful feeding from the ore-bin into a shaker and dump box just above the rifles.

The portion of the water which is retarded by the rifles rises over the chamfered back, and, meeting the swifter down-coming stream above, it is deflected over the sharpened edge. This action can be readily seen with clear water, the particles of sand being picked up and carried over while the gold, undisturbed, accumulates under the projecting inclined face of the rifle. As to the grade, the practice in Manhattan has settled down to 1 in. per foot, but I find that $1\frac{1}{4}$ in. per foot gives better results. This, however, must be regulated by local conditions. A sandy gravel will not require as much fall as one containing much flaky material, such as slate from the bedrock. A great deal of the Manhattan gold is found in the crevices of the bedrock, so that it pays at times to take up as much as six inches of it and sluice all together. For this reason a medium grade must be selected. Water being scarce in this camp it is pumped from the workings by a two-inch centrifugal pump in the tailing-pond, and is used over and over in the sluices. The coarse gravel is screened off with a shaker having perforations about one inch in diameter. The washed barren waste goes directly into a ear from the shaker, and is dumped.

Manhattan, Nevada, February 17. L. F. CLAR.

The Editor:

Sir—It seems that Mr. J. W. Dunham has hit upon a general-purpose idea for the poor man or the one of close

figuring when he found that rifles with a decided undercut or overhang at the upper edge are better than the square-cornered ones.

I had never heard of the overhang rifle being used in sluicing, but have known of its being claimed to save an added 50% of gold in dry washing of dry dirt. It is said to save the flour gold where the square-cornered rifles pass nearly all of it over. Al Stevens did a lot of experimental work at dry washing at Rawhide four or five years ago and claims that the construction of the riffling is just about half the problem and can often give fully double the returns with other conditions equal. He has described his final arrangement as having had several duplicate rifle-frames all fitting snugly and quickly interchangeable so as to create in changing them no more than a pause in the machine's work after the operation was once started. There was always the chance to do repairs at night after that. He showed me a rifle-frame that was undercut at the upper edges of the rifles about twice as much as your illustration.

I am not now positive but think that the old concentrator plant at Butte had all its rifles, which were wooden, undercut on the upper edges or sides.

The Reduction of Hematite

The Editor:

Sir—A communication in your issue of February 2, from Mr. Thomas French, on the reduction of hematite to metallic iron by oil, recalls to my mind a similar occurrence.

Some years ago I received a package of mineral chipings and nuggets with a statement of their source and a request for an analysis and an explanation of the phenomenon. The letter accompanying stated that the writer was engaged in drilling for coal. The drill-tool had been passing through very hard limestone when it encountered a much more resistant substance that delayed operations for several days. In penetrating or otherwise disposing of the hard material the sludge brought up the chips and nuggets and afterward entered shale and softer limestone.

Examination showed that the surface formation was Permian, and doubtless the metal came from the line of contact with the Upper Carboniferous shale. The chips and nuggets proved to be remarkably pure iron, over

99%, so soft and ductile that it could be rolled into paper-like sheets. Larger pieces, weighing several grammes, when polished and etched gave no evidence of Widmannstätten figures.

I accounted for the iron on the theory that it had been reduced from bog-iron or limonite by the organic matter in the underlying shale. In passing I would suggest that whenever metallic iron is found under circumstances similar to those mentioned, its origin—whether meteoric or terrestrial—be first determined. It is of some scientific interest to be able to correlate meteorites with geological structure.

R. H. NICHOLSON.

Lincoln, Nebraska, March 7.

Geology of the Success Mine

The Editor:

Sir—In your issue of January 5 there is a communication from S. R. Moore under the above heading. It may be divided into two parts. The first draws a tentative conclusion from a series of observations extending over a period of years. He says, referring to the idea that granite (monzonite) has been replaced by ore, “from a physical point of view, there always appeared to me to be a doubt, since, in all specimens of granite containing stringers of ore, these are invariably a continuation of quartzite stringers partly replaced, and the question always comes to my mind whether these stringers might not be a replacement of quartzite stringers in the granite, the quartzite having been entirely replaced.” To those who may have taken some interest in the controversy as to the priority of the ore and granite in the Success mine, I desire to call attention that this is the testimony of the man who has been superintendent of the mine for a number of years, throughout the period of greatest activity. As testimony, without regard to the conclusion his remarks seemingly imply, it is in line with the position that I have taken in the matter of the relation between the ore and granite.

The second part of Mr. Moore's letter describes a nodule of granite nearly as large as a hen's egg entirely surrounded by ore. He has kindly mailed to me the evidence. It consists of half-a-dozen fragments of dark reddish-brown sphalerite ore. There are traces of galena, pyrite, and chalcopyrite. There are also a number of residuary patches of the rock or rocks replaced. The larger patches at least are unquestionably monzonite. I was unable to fit together the six fragments so as to enclose the 'nodule' nearly as large as a hen's egg, but a patch about an inch long and half as broad certainly disappeared from view when two of the rock fragments were adjusted in accordance with instructions contained in a letter from Mr. Moore. However, this nodule may be connected with the larger one in the interior of the large fragment. Therefore, so far as the evidence now stands, it is not proved that a nodule of granite was entirely surrounded by ore. I have not been authorized to break the large fragment to learn whether the suggested

connection exists. If Mr. Moore breaks the fragment and finds such connection does not exist, it does not matter. The ore minerals penetrate the monzonite in a manner to prove conclusively that those in the monzonite are younger than the intrusion. I will go so far as to concede that the monzonite is residuary, probably isolated fragments in the ore. J. B. Umpleby has proved, in a paper published in the February-March number of 'Economic Geology', that such replacement has occurred on a limited scale in the Success mine, but in a later issue of the same journal I take the position that it has been the result of limited migration of the sulphides of earlier veins closely following the intrusion of the monzonite into these veins. It is a mighty simple mineral deposit that does not yield evidence apparently supporting contradictory theories of origin. In this case, I believe the preponderance of evidence is in favor of my view. For instance, I feel inclined to give much more weight to Mr. Moore's observations extending over a period of years, than to his discovery, after these years, of a 'nodule' of granite enclosed in ore.

OSCAR H. HERSHEY.

Kellogg, Idaho, March 10.

Colorado Smelter-Charges

The Editor:

Sir—I note in your issue for March 23 a letter from Ouray regarding the charges made by our local smelters for treating ores. If the writer will read the recent report of O. R. Whitaker to the Smelter and Ore Sales Investigation Committee appointed by the last legislature he will see exactly what has become of that percentage of the value of his ore that he did not receive. This report is most illuminating and should help to do away with the lingering thought in the minds of most shippers that the smelters are getting more than their fair share of the value of the ore they receive. It shows that for the five years, 1912 to 1916 inclusive, the gross value of the metal content of the ore received averaged \$26.86 per ton. Of this total \$17.95, or 66.83%, was paid to shippers and for freight, the cost of smelting was \$4.35, or 16.20%, metal losses were \$1.34, or 4.99%, refining and marketing cost \$1.66, or 6.18%, leaving an operating profit of \$1.36, or 5.80%.

HORACE F. LUNT.

Colorado Springs, Colorado, March 23.

CRUDE OIL produced from Scotch shale in 1913 amounted to 1,718,000 bbl., corresponding to a recovery of about one-half barrel per ton of rock treated. The yield of ammonium sulphate, as a by-product, was 300,000 tons from the same quantity of rock. The Scotch shale now supplies large amounts of oil for the British Navy.

COAL-TAR, so much used in flotation of ores, is recovered in large quantities from by-product coke-ovens. The tar is also used as fuel for metallurgical furnaces, being fed like ordinary petroleum fuel-oil.

Men and Machinery

By T. A. RICKARD

While I was at Miami, last May, a club building, just completed, was transferred to the Y. M. C. A. management. This event seemed to me to have much significance. An attractive building containing a reading-room, a gymnasium, a swimming-pool, and a number of bedrooms, had been built by the Miami Copper Co. at a cost of \$91,000, and Mr. J. Parke Channing, the vice-president and consulting engineer of the company, had contributed an additional \$10,000 to furnish it. The building was not at the mine but in the town, and was intended for the use not only of the Miami Copper Co.'s employees, but for those of the neighboring mines and for the people in the town itself. Mr. Channing arrived in time to execute the deed of transfer to the Y. M. C. A., and participated in the opening ceremonies, which were well attended. It was pleasant to note the abstention from any suggestion of patronage, and that the gift was accepted by the people of Miami in the spirit with which it was offered. By making it a Y. M. C. A. club-house the mining company showed good judgment; it saved the employees the irksome feeling of being entertained by their employer, and at the same time it assured the institution an efficient management. Such a club-house in the town, not at the mine, tends to draw the miners and the townspeople into friendly acquaintance; it becomes a conservative factor, because the townspeople desire the prosperous operation of the mine on which their own prosperity depends and therefore they do not favor strikes or other labor disturbances; above all, such a club-house tends to promote Americanization, that is, the assimilation of the foreign elements in our population.

At that time one-third of the working force in the district was American and British, one-third was Mexican and Spanish, one-third was from Austria, the Balkans, and other parts of south-eastern Europe. All received the same pay for the same class of work, but the Mexicans were confined largely to surface work. High wages were being paid at Miami, and men were attracted thereby from other parts of the South-West. The scale of wages was as follows:

\$5.40 for miners and mill-men.

\$5.90 for mechanics.

\$4.65 to \$5.15 for white laborers, helpers, and miscellaneous surface-workers, the exact rate depending on individual efficiency and length of service.

\$3.65 to \$4.15 for Mexican laborers on the surface, the exact rate depending upon individual efficiency.

In passing the office of the foreman at the No. 2 shaft I noticed a line of men awaiting their turn to apply for work. They sat by the roadside, in the warm sun, chatting or smoking. Most of them had come, not long ago,

from Servia, Montenegro, Croatia, Dalmatia, Bosnia. They were Slovenes and Jugo-Slavs. A group of Mexicans caught my eye; these, like many others, had crossed the Rio Grande to avoid the dangers of misrule and the even greater danger of starvation. The Miami mine, as has been shown in the technical description of underground methods, employs few miners and these are mostly Americans or British. The lower kind of manual labor shoveling and wheelbarrow work—is done by laborers to whom the more honorable term of 'miner' is not applicable. By the law of Arizona it is not allowable

THE Y. M. C. A. BUILDING AT MIAMI

to ask a man, when applying for work, where he has been employed previously; it is illegal even for the foreman in one department to dismiss a laborer and then advise the foreman in another department in the same mine not to employ him. It is permissible only to ask the applicant what is his name, nationality, age, whether married or single, how many dependents he has, whom to notify in case of accident, and what kind of work he wants to do. These regulations were enacted, at the instance of the State Federation of Labor, to prevent black-listing. The result is illogical, for the only way left to ascertain what a man can do is to try him. Many men claim to be miners who are not, so that a great waste of time and energy, with considerable confusion, is inevitable. While watching the crowd of 'bohunks,' as they are collectively labeled in the vernacular, I saw a Mexican pass with a number of green leaves on a skewer; these were the young leaves of the prickly cactus, to be eaten like spinach. An occasional Indian strode past, with characteristic gait, throwing the weight of the body forward. The San Carlos reservation is 15 miles away, and the Indians are allowed off the reservation so long as they behave them-

and Mill

Power-plant

selves; if anyone does not, he is reported to the Agent, and either recalled or brought back. They do not like to stay on the reservation; life there is too monotonous and they can make more money on the outside. The law grants them the privilege of squatting on any vacant land in the district, all of which was once theirs, and they can travel without payment on any train that crosses their former hunting-grounds.

Miami is an ethnical melange; so are most of the copper-bearing districts of the South-West. People there talk about 'nationalities' when they mean races. The laborers from south-eastern Europe are as 'foreign' as the Mexicans, perhaps more so. Not many of them have learned to speak English; they know the few words necessary to take simple orders from a foreman, and they herded together, so that they are slow in acquiring the language and customs of this country. They represent an unassimilated lump in the social economy. Many of them expect to make a little money and return to the country of their origin, but in the end most of them remain and become a part of the ethnic complex out of which the American people is being evolved. It is important that they should be assimilated as rapidly as possible, and to do this no institution is more useful than the Y. M. C. A. club-house, where they learn to speak English and to promote a good understanding with the other members of the national family. Moreover, now that the saloons have become a thing of the past, the workmen in Arizona find it pleasant to have a place where they can foregather. The Y. M. C. A. serves as a rest-house and a social centre; it is particularly helpful to the unmarried men and boys, by whom the gymnasium and pool are keenly appreciated. The humanizing effect and the civilizing influence of such an establishment are understood best by men that, like myself, have known the 'mining camps' of an earlier day, when the saloon and the hotel afforded the only rendezvous.

Extravagance among employees is the natural conse-

quence of higher wages, just as increase of income causes employers to indulge in more luxury. The miner at Miami has not gained much from the high price of copper, if gain be measurable in savings. Formerly he received \$3.50 per day and had to spend \$2, leaving \$1.50, out of which he put aside \$1; now he receives \$5.40, the cost of living has increased 50%, so that he has a margin of \$1.65, but he keeps barely half of it, so that his saving is less than it was formerly. This, of course, is a rough and ready way of stating the economics of the mining community. He has had the fun, however, of spending money, and that is a childish pleasure that most grown men enjoy. At Miami the miner's breakfast costs him 30 cents and his supper 50 cents. The 'lunch' that he takes with him to the mine is usually prepared at a restaurant for 40 cents. A room costs \$10 per month. Board and lodging therefore amount to about \$46 per month. The miner pays a hospital fee of \$1.35 per month and if 25c. be added daily for a round trip by automobile the minimum expenditure is \$54.85 per month as against wages amounting to \$151.20. I saw a Mexican going to work with a thermos bottle. Speaking of 'lunch,' I met a number of men going to the mine on foot and carrying brown-paper bags containing their mid-day meal, bought at a restaurant. The tin-plated dinner-pail is going out of fashion. I remember seeing paper-bags hanging by a string from the timbers underground; this was done to circumvent the rats. The miners now buy gramophones; they have acquired a taste for the joy-ride in an automobile. A well-informed citizen explained to me that the 'muckers' had Fords, the shift-bosses Overlands, the foremen Hudson super-sixes, and the managers Cadillac eights. It was evident that the buzz-wagon had become a thoroughly democratic vehicle of transport. In the gulch near the Inspiration shaft I saw a dozen automobiles waiting for the men about to go off shift. I met a motor-lorry carrying 40 workers on their way home from a 'graveyard' shift at

Road to Globe

Inspiration Mill
Miami Mill-dumps

International Smelter

the Inspiration. Fully one-half the men employed at that mine go to work in this way, paying \$7.50 for 30 round trips. Others travel by 'jitney', paying 35 cents each way, from the mine to Globe. In contrast to these new-fangled ways I saw an old-fashioned wagon and trailer pulled by five pairs of horses, the driver riding the wheel-horse, on the road from the Black Warrior mine to the International smelter. This seemed a curious survival from a bygone day, in comparison with so many technical novelties. Neophobia—the fear of anything new—is not a failing noticeable at Miami. The description of the methods of mining and milling shows initiative and originality, but perhaps the most remarkable evidence of mechanical ingenuity is to be found in the Inspiration compressor-house where two hoisting engines work automatically.

The Inspiration hoist is one of the marvels of Arizona. The visitor enters a large building in which the raising and lowering of the cages in the two twin-shafts of the mine are done without the control of an engineer. The two engines work automatically, independently, and in balance. One starts before the other comes to rest; the engine that is stopping gives an impulse to the idle one. This overlap is variable and adjustable. Each hoist is driven by a direct-current motor the power from which is 'on' or 'off' in accordance with the cycle of movements. As I stood and watched the ponderous mechanism at work with clock-like precision, one drum revolving and coming to rest as the other began its slow revolution, winding or unwinding the heavy steel rope that raised or lowered the cages in the two shafts, I marveled to see the levers move to and fro on the engineer's platform as if operated by spirit hands. It was uncanny. The movement of the hoist shifts the levers, instead of the lever controlling the switches.

Each hoist has one fixed and one clutched drum of 10-ft. diameter by 65-in. face, grooved for 1000 ft. of 1½-in. rope in one layer.* The brakes and clutches are

moved by compressed air. Each hoist is operated by a 580-hp. motor electrically connected to a generator set, and the speed of the motor is controlled by increasing or decreasing the voltage from its generator. A 10-ton fly-wheel 9½ ft. diameter serves to store energy for meeting the high power required when starting the load. Before beginning automatic operations each drum must be clutched in position for the loading-level, one skip in each shaft resting on its chair below the loading-chute. The automatic control is introduced by closing two small switches and locking the two clutch-levers on the engineer's platform. Then the cycle of automatic movements is actually started by means of a master controller, like a street-car controller. This control-lever is moved so as to start the small motor that moves the controller of No. 1 hoist to the full-speed position, and at the same time moves a device that releases the brakes on the No. 1 hoist. As the hoist-controller is moved forward it increases the voltage to the hoist-motor and brings the hoist-drum gradually to full speed, raising one skip in the shaft while the other skip descends. Just before the loaded skip enters the dumping-horns the No. 1 controller, actuated by cams geared to each drum, moves to the 'off' position, reducing the voltage and slowing the revolution of the drums. The operation is so timed that No. 1 controller reaches the 'off' position just as the descending skip lands on the chair under the loading-chute at the loading level. The retardation is completed and the brakes are applied. Before No. 1 hoist comes to rest, it starts the pilot-motor for the controller of the No. 2 hoist, which then begins a series of movements exactly duplicating those described for No. 1 hoist. To increase the capacity of the plant the electric control is set so that each hoist will start revolving earlier in the cycle of movements. The maximum capacity is 16,000 tons in 14 hours.

*Technical details are given in the paper by H. Kenyon Burch and W. A. Whiting in Trans. A. I. M. E., Vol. LV, pp. 10-24.

To understand the operation of the hoist it is necessary to go underground and watch the automatic loading of the skips, on the haulage-level, at 585 ft. from the surface. Each ore-car holds 5 tons, and itself weighs 3500 lb. A 10-ton two-stage air-driven locomotive pulls 20 cars or 100 tons of ore. The exhaust of the locomotive suggests a railroad train. The track is 40 lb. A. S. C. E. rail and the grade is 0.4% in favor of the load. Instead of link-and-pin connections the cars are equipped with half-size freight-couplers. No roller-bearings are used, only solid brass journals of a miniature railroad type. All the train-men carry whistles about their necks because speech is impracticable amid the uproar made at the loading-station. An Aldrich triplex geared electric pump, lifting 47 gal. per minute, contributes its share of noise, but it is hoped to diminish it by using a rawhide pinion. The ore-car is a plain box. The train of 20 cars moves into a tippie, one car at a time. A springless car is required on account of the necessity for a close fit in the tippie while the car is being dumped. When the load is released, the springs would expand and wedge the car in place. If the ore happens to be so moist as to be sticky it cakes on the bottom, so that cars have to be sidetracked while the caked ore is broken by aid of a pick.

This automatic hoist sets the pace for the mine, compelling all the operations to keep step. Sixteen thousand tons is hoisted per day. A big margin of time is available for loading, so that there is no danger of the skip moving before the 'cartridge', containing the unit of load, is emptied. The skip stays for about a minute. One skip is dumped per 50 seconds.

One may consider that so big and complicated a mechanism should not be trusted to operate without human interference, forgetting that it is the human factor that introduces unreliability and aberrancy. Even clock-like precision has its limits, for a clock needs to be wound. No engineer trusts an automatic machine unless the automatic device comes frequently into operation; disuse may render the stand-by machine ineffective when an emergency does arise. At the Inspiration the mechanical engineer sees that the safeguards applied to the elevators used in hotels and office-buildings have been applied to the operation of a mine-hoist, and he recognizes the fact that the automatic feature is possible only where the conditions of hoisting are uniform; if the ore came from a number of levels, it would be necessary to place an engineer at the control. These hoists can be operated by hand. If one shaft is not in use, on account of repairs to a skip or loading-tippie, for example, an engineer is placed on the platform in the engine-room. As it is, when operating automatically, one chief engineer and three staff-engineers (one on each shift) are employed, and each is assisted by an oiler. Two electricians, one by day and one at night, are in attendance. Thus we see that the automaticity is hedged around with human safeguards. Once a cable broke, whereupon the man in charge pulled the electric switch, which shut off the power, applied the brakes, and held the empty skip from

running away. A shift-engineer was walking about, as I saw one at the time of my visit, within reach of the switch-plugs. It is intended to distribute electric-contact buttons over the engine-house so that they can be quickly accessible in case of emergency. The men have the use of a cage traveling in the third compartment of one shaft and operating against the counterweight† moving in the third compartment of the other twin shaft. The cage is a double-deck Otis elevator capable of carrying 36 men, 16 on the upper deck and 20 on the lower. The operator stands on the upper deck, where also are the telephone, annunciator, incandescent lamp, emergency switch, and operating switch, the last being self-centring and coming to a neutral position as soon as the operator's hand is removed from it. A second operating switch is in the engine-room, and by means of it the engineer on the surface can operate the hoist when necessary. At each landing there are 'up' and 'down' buttons, as in a hotel or office-building. These connect with the annunciator facing the operator on the cage. Each landing has a telephone that connects with the cage and with the engine-room; it also has two platforms so that both decks of the cage are accessible simultaneously.

While looking at the Inspiration hoist I was impelled to imagine what an unsophisticated Cornishman would say when he saw it for the first time. Mr. Channing helped me by relating a story of which Capt. James Cundy was the hero. This old Cousin Jack went from the Menominee range to the Hotel Pfister at Milwaukee. Coming out of his room he saw the elevator and did not know how to stop it. A maid was passing, whereupon the following conversation ensued:

"Eer, my deer, 'ow do ee get thay cage?"

"Press the button, Sir."

"'Ow many times do ee ring?"

"Once."

"'Ow many times to make ee come hup?"

"Only once, Sir."

"And 'ow many times to make ee go deown?"

"Just the same, once."

"Well now, my deer, where I do come from they rings three times for to go hup, two bells for to go deown, and one bell to stop. Here's a quarter, go's along and buy thee some ribbins."

Various elements in the labor force develop liking or skill for special tasks. Thus the unloading at the smelter is done by Greeks; the roustabouts are either Mexicans or Indians; most of the furnace-men are Irish. The Cornishman is to be found underground, working amicably with the native-born American. I emphasize "amicably" because there have been times and places when and where the relations between the two were not cordial. For example, the story is told that a group of Cornishmen had a mine on lease, or 'tribute', when some

†This is in the form of a small cage that suffices to carry two men for the purpose of inspecting the shaft or making repairs. 'Otis Passenger Elevator at Inspiration Shaft,' by C. E. Arnold. Trans. A. I. M. E., February 1918.

Americans bought the property over their heads and terminated the lease, putting the Cousin Jacks to work on company account. They were disgusted. At a meeting called by the men to discuss the crisis, it was suggested that they test the efficacy of prayer, whereupon one good Wesleyan lifted his voice in supplication, as follows:

"Deer Lorrd, take they bloomin Hamericans and cast they deown to the bottommost depths of 'ell, theer lave they fry and sizzle till they give we our just tribute; then, deer Lorrd, take they hup, greasen they a bit, and put they back hin their 'igh places.'"

As Mr. Arnold piloted Mr. Channing and me through

of a mine of that name with which I was connected professionally in 1892 and 1893, before the railroad was built. It was too dark to see anything, and I was informed that the mine was several miles from the track. The rich vein of complex ore that was mined at Hillside traversed schist capped by basalt—the 'malapai' of the miner in the South-West. John Lawler discovered the vein in a gulch where erosion had worn through the basalt into the schist, and the later workings of the mine had been extended under the basaltic blanket. The question arises whether many rich ore deposits may not lie covered by such Tertiary and Quaternary flows of lava,

THE INSPIRATION HOISTING ENGINES

the Inspiration mine, I remarked upon the usefulness of such visits as between the technical men employed by neighboring companies. Not only does it promote goodwill, in itself a benefit to the community, but it leads to the comparing of notes and the exchanging of ideas. The hammering sound due to the irregular passage of air through the pipes led Mr. Channing to suggest that if the compressed air be passed through the shells of an old multi-tubular boiler, for example, it had the effect of breaking the impulses from the piston of the compressor and preventing useless noise and waste of energy. The sight of a Rand drill at work with its octagonal steel reminded us of the time when it was necessary to use lugs on the round steel. That simple invention of octagonal steel was a great boon to the miner.

Going from Phoenix to Prescott the train passes a station named Hillside, where I had hoped to see something

and whether the time may not come when systematic boring will be undertaken in the search for such hidden wealth. The story of the U. V. X. mine, at Jerome, gives further point to this suggestion, for there the lava was not only the surficial rock but overspread the limestone under which, if the limestone had been visible, the existence of the ore-bearing schist might have been more quickly inferred.

At Prescott I found the old Burke hotel had changed its name and on the door of the bar-room the traveler read the significant notice 'Out of Order'. It seemed strangely quiet compared with the lively times of 25 years ago. But Prescott itself can boast a handsome new Court House and retains the air of a comfortable hometown. It is just a mile above sea-level and enjoys a climate as near perfection as anyone would wish. The Thumb Butte and the other granite hills provide an

agreeable background, and, on the whole, I confess to having been to few mining centres so agreeable as Prescott.

From there the railway runs through granite country, exposing clean-looking massive bouldery outcrops rising above a high-level plain, which must have been a lake-bed, as is suggested by the conglomerate detected in a railroad cutting. The train crossed these sunlit uplands toward a range of hills darkened with forest and shadowed by clouds that had distilled a shower of fresh snow, now graying their summits. At Jerome Junction the traveler for Jerome leaves the main northward line and takes a crawling narrow-gauge train that winds its devious way from the high plateau into the valley of the Verde. On his way he sees the succession of rocks constituting the geologic terrain of the rich copper mines at Jerome. A trench and a prospector's stake near the railroad explain man's irruption into this vast desolation, for, as the train follows a descending contour, the intermittent views of the wide Verde valley and the opposite mountains of the San Francisco range afford a perspective so expansive as to emphasize the insignificance of human interference with the order of nature. Soon a winding ribbon of green cultivation is discerned far below in the valley, and the smoke emerging from a black chimney marks the Clarkdale smelter, where the ore of the United Verde is treated. Formerly the smelting was done at the mine itself and the effects of the fume made by heap-roasting are to be seen in the barren darkly red slopes over which the railroad reaches its terminus. The train stops suddenly at a small freights-shed on the edge of a big open-cut. The traveler finds himself high on a mountain-slope close to the old workings and the abandoned slag-dump of the United Verde mine, overlooking the dreary hillside to which the little town of Jerome clings in sheer desperation. Senator Clark has provided as unpleasant a terminus for his railroad as any that I have seen. He dumps the arriving passenger upon a bleak mountain and tells him to shift for himself. Luckily, I did not have to do that, for at once I became the beneficiary of Mr. James S. Douglas's hospitality. In other articles I have described the famous enterprise that Mr. Douglas has created and that has led him to build a graceful *casa* on the ridge reaching forth from the malapai slopes through which he has penetrated in his successful search for copper ore.

At Jerome one sees more of the labor problem and of the even greater problem of Americanizing the heterogeneous foreign elements that do so much of the work of mining. While I was at Jerome a strike was started, the unskilled workers demanding the Miami scale of wages. That did not seem unreasonable, for Jerome is a worse place for living than Miami. The difficulty was not faced firmly by the management of the United Verde, largely because the owner of that mine lives in New York, and apparently the resident manager was not free to act on his own judgment. Hence the representatives of the miners were referred first to New York, then to Los

Angeles, where Senator Clark's son lives, and then back to the resident manager, and in the process of postponement and indirection the labor leaders became irritated. The question of striking was put to the vote, but less than a third of the men cast a ballot, for fear of committing themselves, and a large number of the steady workers left the town rather than participate in the trouble that was impending. I heard one of the labor leaders—an 'agitator'—make a speech from a band-stand in what might be—but is not—a park in the centre of the town and I discussed the matter with one or two of the managers, coming therefrom to the conclusion that the friction between employers and employees could have been avoided by the prompt display of firmness and fairness. Why a car-man or a chuck-tender living in such a miserable place as Jerome should be content with a lower wage than is paid for the same work at Miami, I do not see. At Jerome a decent room for a single man costs \$20 to \$25 per month. Two men can share a small room for \$20. Good board costs \$1.25 per day, the average being \$8 per week. Supplies of all kinds are costly, partly because the town is served by a railroad that is controlled by the owner of the United Verde mine. The distance to Prescott is 65 miles by an automobile road; if a direct railroad connected Jerome with Prescott there would be easy access to a pleasant town and reasonable amusement, but the store-keepers at Jerome fear a diversion of trade and the Clark interest would object because it would interfere with the control exercised by the existing railroad.

Speaking of costs, Mr. McGregor told me that the expenditure to be made on the United Verde Extension company's new smelter in the Verde valley would be just double what it would have been five years ago. The higher price of labor, and the lower efficiency, doubled the cost of grading. Likewise structural steel cost twice what it did when the Calumet & Arizona smelter was built, and the other parts of the equipment cost $2\frac{1}{2}$ times as much. This smelter, by the way, is to have a capacity of 1000 tons of ore daily; it is to make a 38 to 40% matte. The ore contains a slight excess of silica and will require the addition of lime, which is plentiful near the site of the plant, seven miles from Jerome. The ore at present is delivered by a Leschen tram, 4600 ft. long, to the railroad, thence to the smelters at Bisbee, Humboldt, Douglas, and Globe. The U. V. X. smelter will cost \$2,250,000.

While visiting the smelter-site I was introduced to an Apache of pure breed, named George Washington Hunt. He was born near-by, at Cottonwood, on the Verde river, and was working as a junior engineer in charge of the grading. He spoke good English, having been educated in the Indian school at Grand Junction, Colorado. The dignity and natural poise of this real American were pleasant to observe, contrasting agreeably with the mixed submissiveness and impudence of the riff-raff from south-eastern Europe.

†See also 'Features of the New Copper Smelting Plants in Arizona.' Trans. A. I. M. E., Vol. LV, pp. 781-805.

Jerome, as seen from below, appears as a cluster of yellow, blue, and white boxes on stilts clinging to a barren hillslope. Until 1897 Senator Clark roasted his ore in heaps and made a hades of the place where his work-people lived. On nearer view Jerome does not improve. It is a blot on our democracy that citizens should live

employed, many of whom he had known in other parts of Arizona. "Hullo Jim," and "Hullo Dick, Tom, or Harry," as might be, were the salutations that passed. Mr. Douglas has found no difficulty in determining his attitude toward those less fortunate than himself. His democratic manner has not lost him either the

dignity or the respect that is the meed of a successful captain of industry. On turning to the list of members of the American Institute of Mining Engineers, I find that James S. Douglas described himself as 'miner.' With that label I feel inclined to quarrel as incorrect, for I know him to be an accomplished technician, fully competent to devise and direct the operations of mine and smelter. If he were a 'miner,' without further ado, he would not be a member of the Institute. Still I like the sin-

THE MAIN STREET OF JEROME DURING THE STRIKE

amid such surroundings. The muddy roadway that served as a street, the crowded dirty sidewalks, the polyglot population, left an impression of industrial conditions that are in a rudimentary stage of development. The mining companies ought to build houses for their employees and try to do something to establish a reasonable standard of living. It is a manifest social wrong for a few men to draw wealth from these mines — from two of them at least—and live, as most of the owners do, in luxury in distant cities, while the work-people have to exist like castaways on a deserted island in the midst of this desolation, without any apparent attempt being made to mitigate the natural discomforts of the locality.

Passing with Mr. Douglas through the crowd along the muddy thoroughfare it was interesting to note the contact between the millionaire mine-owner and the men he

JEROME AND THE UNITED VERDE MINE

cerely democratic spirit shown by him in all that he does, now that I know him to be solicitous for the welfare of the men he employs and willing to leave his profitable enterprise at Jerome in order to do such work as an American of his age can perform 'somewhere in France.' Such men as he, with their recognition of the duties of citizenship, are likely to contribute to the solution of the problems that will perplex our industrial democracy with increased insistence when we have won the War.

The Metallurgy of Mercury

Furnace treatment will continue to be the method used for recovering mercury from cinnabar ore, as indicated in the discussion at a recent meeting of the San Francisco Section of the American Institute of Mining Engineers. With improvements in calcining and condensing, the two essential operations in current practice, the old process will prevail. Wet methods of extraction cannot compete in cost of operation with reduction by means of present furnaces. As a result of co-operation between the California State Mining Bureau, the U. S. Bureau of Mines, and the companies producing quicksilver, a series of investigations has been made during the last three years, and two publications on the subject will be issued soon. At the meeting mentioned, W. W. Bradley, of the State Mining Bureau, who has had charge of the research, gave some valuable information. Of the 20 species of mercury minerals, only three are of commercial value, namely, cinnabar, meta-cinnabar (the black sulphide), and native quicksilver. There is little literature on the metal. Its metallurgy is simple. Producers have been satisfied with the recovery, and up to 1916 little sampling and assaying had been done to determine the percentage obtained. No systematic investigation in concentration was done until 1913. For calcining ore, the D-retort is useful only for high-grade ore and concentrate. The Scott furnace was designed in 1875, and may be styled the standard in California. It consists of a shaft in which are tiles or shelves set at an angle, staggered, down which the ore travels to the bottom, where the fire-box is placed. Ore is drawn out at intervals. The disadvantages are considered to consist in too much handling and too much time consumed—24 hours being required for the ore to pass through. This furnace should not be used for drying ore. Until recently, fuel economy and temperature control have not been studied, and pyrometers should be installed. The consumption of too much air increases the consumption of fuel and is a detriment to the condensing system. The absorption of mercury is large where brick and cement are used in the furnace. The cost of operating the Scott furnace is from 50 to 75c. per ton, plus 25 to 50c. for other charges. The recovery from one ore, assaying from 0.26 to 0.36% mercury, was 91.3%, and at another, under careful supervision, treating 0.66% ore, it was 86.6%, but Mr. Bradley said it was doubtful whether over 75% has been recovered by average furnace practice in California. He stated that revolving furnaces had not been successful, although at New Idria one recently erected is working well at present. In multiple-hearth furnaces, such as the Herreshoff, dust was a nuisance; but with the Cottrell precipitator this was avoided. At Almaden one of these furnaces is now at work. Condensers have been constructed of brick, but wood is preferable, as it does not absorb mercury. Condensing methods have been erratic in the past. The vertical circular wooden tank seems to be the best condenser. It is necessary that the fume be

cooled as soon as possible after leaving the furnace. The introduction of cooled air is advantageous. Tests made at the University of California showed that in wet concentration of cinnabar the feed must be classified before passing to tables. 'Paint' cinnabar cannot be collected by tables, but the native metal can. By flotation, paint and slime ore can be collected. The specific gravity of cinnabar is 8, yet quicksilver miners considered concentration impracticable. Concentrate must be roasted, but if the mercury content is too high, that is, as much as 40%, this product packs in the furnace. A wet plant would cost half as much as a furnace plant. Sodium sulphide will readily dissolve quicksilver and the sulphide, but the process is not applicable in the presence of a considerable quantity of ochre. The Bureau of Mines, according to L. H. Duschak, first made a study of losses in fume. These were found to be surprisingly small. At New Idria, on 1% ore, the loss was but $4\frac{1}{2}$ lb. per 24 hours. At the Oceanic mine it was $6\frac{1}{2}$ pounds. Water losses, that is, mercury dissolved by acid vapors from calcining, were very low. Condensing consists of two operations, namely, cooling and collecting. Baffling the fume is essential. Good furnace work should yield a clean residue, and at least 90% of the metal should be expelled. At Idria, in Austria, the recovery is 95%. A temperature of 600°C. will expel mercury from one-inch ore in 15 to 60 minutes. Mr. Duschak has great hopes for rotary furnaces. These cost \$250 per ton of capacity against \$1000 for the Scott type, the consumption of fuel is one-third to one-half that of the Scott, labor is one-fifth to one-fourth, and the furnace is automatic. H. W. Gould, of New Idria, said that the rotary furnace has great possibilities. It is more flexible than the Scott, the ore passes through in 15 to 30 minutes, and there is no mercury left in the tailing. There are no absorption losses in the furnace, as all the brick is hot. There is no personal element attached to the rotary, as the discharge is automatic, whereas in the Scott this is irregular. The furnace now working at New Idria is 4 by 50 ft.; it makes from $1\frac{1}{2}$ to 4 revolutions per minute, and treats 96 tons of $1\frac{1}{4}$ -inch ore daily. No salivation of the workmen is possible on account of the joints at each end of the furnace. The new rotary being installed is 5 by 60 ft. Clifford G. Dennis, of the St. John mine, said that his experience was that assays of cinnabar were not satisfactory, in that condenser operations were so erratic that he had recovered as high as 330%. This was due to metal 'hanging up' in the walls of the condenser, and dropping irregularly, preventing checking actual recovery with the theoretical. E. A. Hersam championed the past work of quicksilver producers, praising the work of the Scott furnace. He thought that sampling and assaying cinnabar was much different from that of other ores, and should be done in greater bulk. He has more faith in furnace results than in assays.

POTASH is in strong demand at Pacific Coast points. Sulphate of potash commands \$350 per ton for the 90% grade, and a recent shipment from Japan sold at \$396.

Testing an Air-Compressor

By WALTER S. WEEKS

When a compressor is sold it is guaranteed to have a certain volumetric efficiency by orifice test.

This efficiency is determined as follows: The air delivered per minute by the compressor is measured. The volume of this air is calculated under the conditions that prevailed at the intake of the compressor. This volume is divided by the volume swept per minute by the piston of the low-pressure cylinder. The result is the efficiency sought. The piston rod should be neglected.

The term volumetric efficiency is also used in comparing the performance of a compressor at different altitudes and with different intake temperatures. This use of the term is in my opinion unnecessary and con-

in the compressor-room, so the free air at the temperature at the compressor-room is $\frac{520}{560} \times 1000 = 929$. The compressor will deliver, at this altitude, according to the

FIG. 1. COMPLETE AIR-METER

fusing. The whole subject may be clarified by using the term 'volumetric efficiency' only for that given by the orifice test and stating the air-consumption of tools in cubic feet of compressed air at a given gauge-pressure.

An example, if I may digress for a moment, would be something like this: An air-drill requires 10 cu. ft. of compressed air at 90-lb. gauge. The altitude is 10,000 ft. The temperature of the mine is 100°F. The temperature of the compressor-room is 60°F. What must be the displacement of the low-pressure cylinder to run 10 drills? The volumetric efficiency of the compressor by orifice test is 80%.

Compressed air needed $10 \times 10 = 100$ cu. ft.

Ratio of compression at 10,000 ft. $= \frac{90 + 10}{10} = 10$.

Free air needed $= 10 \times 100 = 1000$ cu. ft.

1000 cu. ft. is needed in the mine at 100°F. It is 60°

FIG. 4. THE NOZZLE

maker, only 80% of the piston displacement, hence the displacement needed is $\frac{929}{0.8} = 1161$ cu. ft.

The vital questions about an air-compressor are: How much does the compressed air cost, and is the compressor doing all that it should?

To answer these questions we must measure our power input, we must measure the air delivered, we must take

indicator-cards on the air end, and determine the displacement.

The measurement of power on the driving side is familiar to all, but a rapid way of measuring the air may not be quite so familiar. The air is best measured by what is known as the low-pressure orifice method (Fig. 1). All the compressed air that the compressor will make is discharged from the receiver through a valve *a* into a tank *b* in which is placed a nozzle or orifice *c*. The valve is closed until the compressor will just hold the receiver pressure desired. The pressure just back of the nozzle is taken with a water manometer *d*, and its temperature is taken with a thermometer *e*. From these data, with the size of the nozzle, the air flowing per minute may be computed.

The flow through an orifice is assumed to be adiabatic, but an adiabatic formula is cumbersome. If we assume that the density of the air is a mean between the density inside and outside the tank, a simple formula can be developed from the basic principle that $V = \sqrt{2gH}$. This simple formula agrees with the adiabatic formula up to 18 in. of water. A discussion of the development of the simple formula may be found in 'Engineering Thermodynamics,' by C. E. Lucke.

The formula there given is pounds of air per second through a circle of

$$d \text{ in. diam.} = 0.01366 d^2 \sqrt{\frac{h_w P}{T}} \text{ (No. 1).}$$

d = diam. of nozzle in inches.

h_w = difference in pressure on the two sides of the nozzle in inches of water (never over 18 in.).

P = mean pressure on the two sides of nozzle in lb. per sq. ft.

T = absolute temperature back of the nozzle in degrees F.

What we are after is the cubic feet of free air delivered per minute under intake conditions. Curves may be plotted to make our computations easy.

To find the weight per minute multiply by 60

$$W = 0.81960 d^2 \sqrt{\frac{h_w P}{T}}$$

First assume the nozzle to be 1 in. diam., the nozzle temperature 60°F., the barometric pressure 14.6 lb. per sq. in., and determine the weight that will flow out per minute with water-gauges from 1 to 15 inches.

After these weights are determined, calculate the volumes under a standard set of conditions by the formula

$$V = \frac{w R T}{P_s}$$

V = volume in cu. ft.

w = weight in lb.

R = 53.34

T = absolute temperature = 520°F.

P_s = absolute pressure in lb. per sq. ft. = 14.6×144 = 2102.4.

We now have the data for curve *A* (Fig. 2). The

values plotted include a coefficient of flow for the nozzle of 0.98, which from various investigations appears to be reasonable.

Now suppose the nozzle temperature instead of being 520° abs. is some other temperature T_1 abs. We can determine the flow by multiplying the values on curve *A* by $\sqrt{\frac{520}{T_1}}$. The air after making this correction will still be measured at 60°F. This correction is plotted in curve *B*.

Now suppose the barometric pressure is not 14.6 but some other pressure P_1 lb. per sq. in. In formula No. 1 P is the average pressure in lb. per sq. ft. Let P_{m_1} be the average pressure in the same units when P_1 is the

FIG. 3. LOW-PRESSURE INDICATOR-CARD

barometric pressure. The flow of air when the barometer is P_1 may be obtained by multiplying values from curve

$$A \text{ by } \sqrt{\frac{P_{m_1}}{P}}$$

Without appreciable error we may use the ratio of barometric pressures instead of the average pressures.

So we may multiply by $\sqrt{\frac{P_1}{14.6}}$ instead of $\sqrt{\frac{P_{m_1}}{P}}$.

After making this correction the air would still be measured at 14.6 lb. per square inch. We want the volume at pressure P_1 so we must multiply by $\frac{14.6}{P_1}$;

thus the total correction will be $\frac{14.6}{P_1} \times \sqrt{\frac{P_1}{14.6}} = \sqrt{\frac{14.6}{P_1}}$.

This correction forms the basis for curve *C*. I have used inches of mercury for the barometer pressure because most aneroid barometers read this way.

After making the corrections for nozzle temperature and barometer we have the air at 60°F. and at the barometric pressure existing. There remains still to compute the volume at the intake temperature. This correction is merely the ratio of the absolute temperatures and is plotted in curve *D*.

The final result must be multiplied by the square of the diameter of the nozzle in inches.

Example of the use of the chart.

Nozzle 2 in. diam.

Water column 8 in.

Nozzle temperature 80°F.

Barometer 30 in

Intake temperature 90°F.

Curve A 60.6 cu. ft. at 14.6 lb. per sq. in. and 60°F.

Curve B, 0.981.

Curve C, 0.995.

Curve D, 1.058.

Square of diam., 4.

Total correction, $0.981 \times 0.995 \times 1.058 \times 4 = 4.131$.

$4.131 \times 60.6 = 250.34$.

The nozzle then is discharging each minute 250.34 cu. ft. air at 90°F. and 30 in. of mercury. This figure divided by the displacement gives the volumetric efficiency.

Let us suppose that we are testing a two-stage compressor driven by a belt-connected induction-motor.

An indicating wattmeter gives the power-input.

The air-cylinders should be fitted with indicators.

Tests should be run at various gauge-pressures. Let us suppose we are running a test at 90-lb. gauge.

All gauges should be calibrated. Discharge all the air that the compressor makes through the nozzle and adjust the valve to the tank till a pressure of 90 lb. is maintained in the receiver. Let the compressor run

under these conditions for 15 minutes. Read wattmeter, water column, nozzle temperature, intake temperature, barometer, r.p.m., and take indicator-cards.

The horse-power calculated from the indicator-cards divided by the horse-power input gives the over-all mechanical efficiency.

From the cost of power, the kilowatt input, and the air delivered, may be calculated the cost of compressed air per unit.

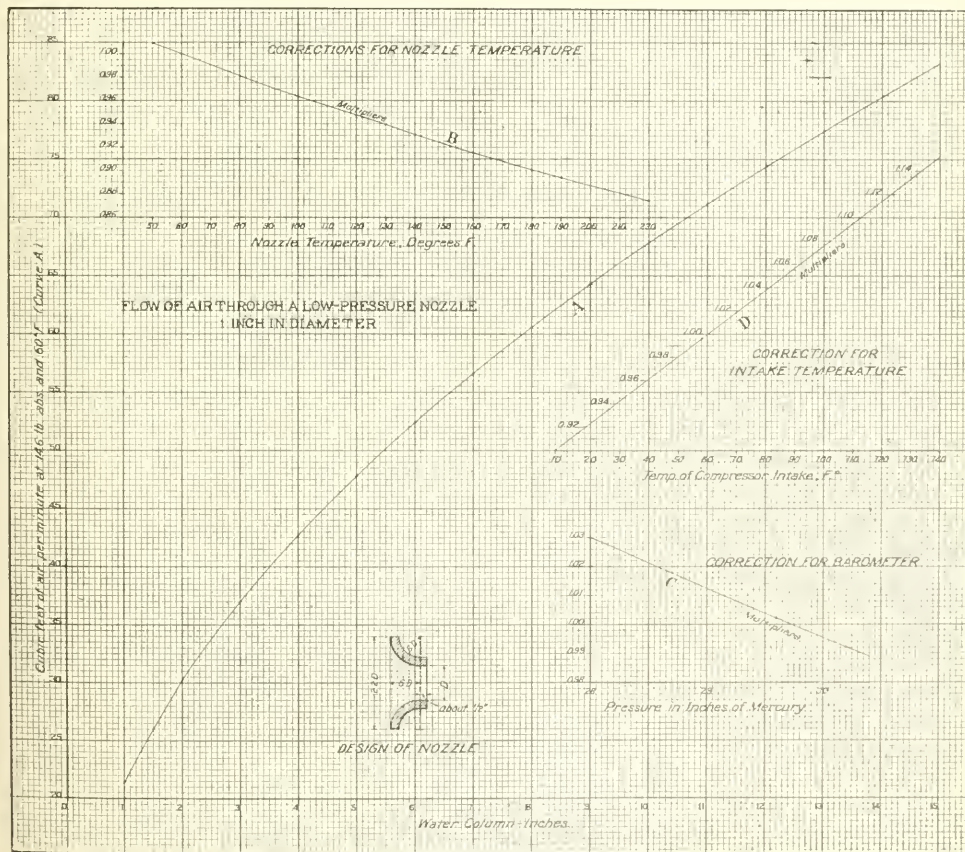

The air delivered divided by the displacement of the low-pressure cylinder gives the volumetric efficiency.

With the aid of the low pressure indicator-card we can determine the slippage.

The actual volume of air taken in each stroke at atmospheric pressure is represented by the length of the atmospheric pressure line included in the indicator diagram. Glancing at Fig. 3: if AB represents a displacement volume K then the volume of air taken in each stroke at

atmospheric pressure is $\frac{CD}{AB} \times K = L$.

Less air is taken into the crank end of the cylinder

than into the head end because the piston-rod takes up room; therefore the displacement of each end must be figured separately.

Let L_1 = volume at head end at atmospheric pressure.

Let L_2 = volume at crank end at atmospheric pressure.

Let S = r.p.m.

Then the number of cubic feet of air that actually enters the compressor each minute at atmospheric pressure is $(L_1 + L_2) S = M$.

The air delivered as measured by the nozzle divided by M gives what is called the slippage efficiency. It is assumed that the air is not heated on its way into the compressor. The air must be warmed somewhat, just how much in a fast-running compressor, I don't know. A little study will show that the warming of the air will make this efficiency appear lower than it really is. Even if the method is not rigidly accurate, it will detect leakage by the piston and through the valves.

S. B. Redfield, testing engineer for the Ingersoll-Rand Co., to whom I am indebted for much information, has used a similar chart for many years in testing the many compressors turned out by the plant, and has found the method most satisfactory. On the chart is a sketch of the nozzle adopted by Mr. Redfield. Fig. 4 is a photograph of a nozzle. A casting should be made of brass and the nozzle threaded to screw into the tank. The nozzle should be polished. For a test a nozzle should be selected to keep the water gauge less than 15 inches.

The area of the tank should be twenty times the area of the nozzle. An even flow through the tank is desired. The globe valve admitting air to the tank may be made delicate by fastening a long lever to the handle. When a compressor is purchased, specification should be made that it be tapped for indicators. These holes are handy in testing the tightness of valves and pistons.

It would be an excellent idea if the makers of air-compressors would agree on a standard method of testing. As the case stands at present a comparison of guarantees is impossible because the compressors are tested by different methods. The important guarantee of a compressor is the horse-power input per 100 cu. ft. air delivered. The way that the air is measured should be carefully scrutinized.

In order that curve A may be plotted to a more open scale, I append the values from which it is plotted.

Water-column in inches	Cu. ft. of air	Water-column in inches	Cu. ft. of air

GOLD HOLDINGS of Japan on December 15, 1917, amounted to ¥1,093,000,000, of which ¥631,000,000 is held abroad (1 yen = 50 cents).

Deepest Well in the World

The deepest well in the world, already 7363 ft. deep, is now being drilled on the Goff farm, 8 miles north-east of Clarksburg, West Virginia. Until January 24 the record had been held by a boring at Czuchow, Silesia, 7349 ft. deep. The drilling is still in progress and sufficient length of cable and adequate power and tools are at hand for driving still farther into the crust of the earth. The depth of this well exceeds the height of Mount Washington (6293 ft.), and it is over half a mile deeper than the Grand Canyon of the Colorado in Arizona. The well goes farther down than the deepest mines in Michigan, Brazil, or Europe. Several oil-wells in California, in the South-West, in West Virginia, and in Pennsylvania have exceeded 4000 ft. in depth, and one near McDonald, Pennsylvania, 14 miles west of Pittsburgh, reached 7248 ft. below the surface. C. E. Van Orstrand, of the Geological Survey, found that at a depth of 7000 ft. in the well the temperature is 152° F. and that the rate of increase at this depth is about 1° in every 51 ft. This shows that the outer crust of the earth in this region is relatively cool, for in many other regions the temperature increases more rapidly. Mr. Van Orstrand estimates that the temperature of the rocks beneath the Goff well will be found at the boiling point (212° F.) at a depth somewhere around 10,000 ft. The Goff well is near the centre of the great Appalachian coalfield basin, or trough, and is being drilled in search of deeper oil-sands than have yet been reached in this part of the basin. The most hope is based on the Clinton sand, a formation of Silurian age, which is prolific of gas and oil across central Ohio from Cleveland nearly to the Ohio river. From its outcrop this formation dips gently to the south-east beneath younger formations. If the drill can reach the Clinton sand beneath the Goff farm, which is on an anticline in the shallower strata, it may find gas or oil under tremendous pressure. If the well strikes a valuable oil or gas pool in the Clinton sand in this part of the basin it may lead to the development of new reserves that may open a new era in the history of the Appalachian oil and gas region.

BY-PRODUCT AMMONIA from coking is recovered as ammonium sulphate. The present output is 200,000 tons of the sulphate annually. Additions to by-product coking equipment in this country will double the production during 1918. If all coking were done in by-product ovens the quantity of ammonium sulphate available in the United States would be about 700,000 tons per annum.

THE PHENOMENON of life has been shown by Amé Pictet to depend upon that structure of an organic molecule in which the atoms are disposed as an open chain. So far as concerns its chemical relations death is accompanied by a change in the molecule that closes the chain, that is, causes cyclisation of the elements of the protoplasm.

Loss of Quicksilver in Gold Mills

By W. J. SHARWOOD

The death-knell of the stamp-mill and the amalgamation process has been so often and so loudly rung by vendors of rival machines and inventors of rival processes that one might almost suppose them to be obsolete by this time. Stamp-mills, however, continue to crush nearly all the gold ore in the world, and amalgamation is responsible for about a quarter of the gold produced in the United States, and for a still larger proportion of that extracted abroad. Mercury therefore maintains its importance in gold metallurgy, though at the present high price there is a natural and increasing tendency to substitute non-amalgamation processes wherever possible.

Much of the mercury used in the stamp-mill, whether fed into the mortar or sprinkled on the plates, is collected again in the form of amalgam and condensed when the latter is 'retorted.' Only a trifling amount remains in the retorted sponge, to be volatilized and lost in melting the bullion. A larger amount is carried off in the tailing, mostly mechanically as floured quicksilver or amalgam, but partly in the form of smears on the surface of particles of ore, and sometimes partly converted into oxide or sulphide. Some of this accumulates in odd corners, or is caught in traps, and cleaned up from time to time. In the cyanide process part of the mercury in the tailing is dissolved, re-appearing later in the precipitate, from which it is sometimes profitable to recover it by distillation. A certain irrecoverable loss occurs, principally in the tailing, but in modern mills, operating on low-grade gold ores, the loss per ton crushed usually ranges from about 0.005 to 0.01 pound avoirdupois, or, say, 0.07 to 0.15 oz. troy. At the prices current for some years before the present war the cost of an ounce of mercury averaged 4 cents, a flask containing about 1100 oz. troy. Since the outbreak of the War the price has more than doubled, averaging about 8 to 10c. per oz., and at times has been much higher. In former times, when milling high-grade ores with small

plate-areas, the losses were often much larger, while the various amalgamation processes (pan, patio, barrel, etc.) applied for treating rich silver ores, consumed enormous amounts, both mechanically and chemically, especially in the days when mercury was allowed to act both as reducing agent and collector, directly replacing silver in the compounds treated.

The accompanying table is the result of an attempt to collate some of the available data on the consumption of mercury in stamp-mills of both past and present. The endeavor has been made to reduce all figures to the basis of troy ounces of mercury per short ton. In a few instances the original writers have not specified clearly what sort of ounce or ton they meant, but the errors possibly introduced in this way are not of serious importance (see table below).

Older data on Australian mills are given by. A. G. Lock, 'Gold: Its Occurrence and Extraction,' pp. 638 and 1019.

A few special cases involve conditions different from ordinary stamp-mill practice, and may be separately considered (see table on next page).

Not much information is available as to the relative amounts of mercury used in the mortar, on the plates, etc., but some data have been published on the practice at the Homestake and Alaska mills. The former use inside amalgamation and have an unusually large outside plate area, averaging 240 sq. ft. per 5-stamp battery; the latter, before abandoning the use of mercury, also amalgamated in the mortar, each 5-stamp battery having a plate of 45 sq. ft. surface and two vanners carrying 18-in. plates.

The ultimate consumption or loss of mercury is no doubt influenced to some extent by the richness of the ore, by the area and slope of the plates, and the relation between their width and length, but more by the condition in which they are maintained as to 'dryness' or 'hardness.' Other factors are the manner of feeding the

mercury, whether into the mortar or outside only, the frequency of removing amalgam and dressing or brushing the plates, the kind of traps used and the attention paid to them. The nature of the ore treated, apart from its gold content, is also an important factor, pyritic minerals generally tending to increase the loss. In small-scale laboratory tests it is, however, noticeable that highly sulphuretted ores often cause less flouring and fouling of the mercury (commonly due to formation of a film of sulphide) than those containing a smaller proportion of sulphide that is in a partly oxidized condition. Pyritic concentrates, when run through a mill after becoming partly oxidized by storage, cause rapid discoloration of plates. No particular sulphide, speaking generally, seems to cause more fouling of the mercury than another, though in individual mines or districts such an effect may be apparent.

Manganese From Steel Slags

The importance of a judicious use of American steel-slags cannot be exaggerated. In 1917, owing to some interesting applications in Europe of certain steel-slags, an investigation of American slags was made by an American metallurgist to discover if any analogy existed. Six important slags regularly turned out by American steel companies are presented in this analysis. They all differ decidedly in their properties. Considering these slags from the standpoint of their value as manganese carriers, the following recapitulation is interesting:

Slag	Manganese oxide, %
Basic open-hearth	2.5 to 10.0
Acid open-hearth	3.0 to 21.0
Bessemer converter	5.0 to 22.0
Manganese steel from converters.....	45.0 to 50.0
Ferro-manganese furnace	5.0 to 12.0
Spiegeleisen furnace	2.5 to 5.0

When manganese ores became scarce, a good market was formed for the high-manganese slag from manganese-steel converters. This 45 to 50% manganese-dioxide slag has been sold to one or two companies making ferro-manganese. It has been used in their regular burden, and a large part of the manganese has been recovered, as well as some of the iron. Open-hearth and bessemer slags, particularly basic, are metallurgically available for use in regular blast-furnace charges, and economically so in many cases, but it is surprising how few pig-iron makers are availing themselves of this advantage. Basic slags are now being run through blast-furnaces to recover the lime and some of the iron, but particularly the manganese. One of the largest pig-iron and steel producers in the United States has in the past year or two raised the manganese content of the basic and other pig-iron from 0.90 to 1.50% by the use of basic slags alone. Some of the phosphorus is also given up, and when this becomes too high the charge of slag is discounted temporarily or for one day.

Slags, as a whole, represent by-products containing valuable ingredients. The basic slags in particular can easily be used, and it is believed that the successful employment of the acid slags can be advantageously accomplished. Bearing directly on these questions is the testimony of one large American steel and pig-iron maker, which is so explicit and illuminating that it is here quoted: "From our open-hearth slag we recover the metallic contents, iron 18%, plus phosphorus 1%, plus manganese 10.50%. This is equal to an ore value of approximately 25% in iron, figuring that we lose 40% manganese in furnace practice. This, of course, will vary according to temperature. Besides recovering the iron, we figure a limestone valuation of about 50%, that is, from every 100 lb. of open-hearth slag in use we get a credit in stone of 50 lb., or we might say that we take off 50 lb. of stone for every 100 lb. of open-hearth slag used. We figure that it costs the open-hearth department

about \$8 per car to waste the open-hearth slag which is saved by using it in the blast-furnace. In another furnace we use bessemer-converter slag, and recover the metallic contents, iron 8.50%, plus manganese 14%, or equivalent to iron ore of 16%. With converter slag we have a silica content of about 58%, which enables us to use a lower silica ore, consequently giving us a richer mix, and at the same time not too dry a burden, which reflects in the coke practice."

In Sweden two different procedures are being carried out for reducing, electrically, acid slags to alloys high in manganese. The first is the use to which slag from their bessemer converters is put. In Swedish practice pig-iron containing as high as 2% manganese is used, the manganese being the chief source of heat, because Swedish pig-iron is very low in silicon and phosphorus. As a result, a bessemer acid slag that is very high in manganese is obtained, sometimes reaching 50% MnO. Another Swedish slag comes from the blast-furnaces that make pig-iron. In producing an iron as high as 2% in manganese the slags have a very high manganese content also. Some are stated to average 20% in manganese oxide. Since the War started, and ferro-manganese and other manganese alloys for steel-making purposes grew scarcer in Sweden, attempts were made to recover the manganese. The Swedish bessemer slag is reduced with charcoal in an electric furnace, by which means a product is obtained containing about 60% manganese, with the balance made up largely of silicon and iron. From another source comes the information that the Swedish blast-furnace slags, which carry about 20% manganese oxide, are treated in an arc electric furnace requiring 1700 kw., and producing an alloy containing 60% manganese and 20% silicon. Because of the high silicon content the usual absorption of carbon is stated to be prevented so that it averages less than the usual 80% ferro-manganese. Reliable information is to the effect that the Germans are carrying out one or both of the electric-reduction methods for slags referred to, and using such alloys as substitutes for ferro-manganese.

A rough theoretical calculation shows a total slag output of about 2,373,500 tons in the United States in 1913, which contains approximately 148,376 tons of MnO, or 114,249 tons of manganese. It was much larger in 1916. The basic slag alone shows a manganese content of 86,159 tons of manganese, most of which is recoverable as manganese in the pig-iron. The acid slags, bessemer and open-hearth, contain 28,090 tons of manganese.

MOLYBDENUM was produced during 1917 from 17 different localities in Canada. The operations of the Canadian Wood Molybdenite Co., at Quyon, Quebec, was the most important. The ores were concentrated at the International Molybdenum Co.'s mill at Renfrew. The Canadian Wood company is building a second mill at Hull, Quebec, and a concentrator is being erected by the Renfrew Molybdenum Mines Co. at St. Patrick. Ferro-molybdenum is made at Orillia and Belleville, Ontario.

Operating Conditions at the Clarkdale Smelter

By L. S. AUSTIN

This smelter is owned by the United Verde Copper Co., operating at Jerome, Arizona. The plant consists of eight 21-ft. Wedge roasters, three blast-furnaces, two reverberatory furnaces, and five 12-ft. upright converters of the Great Falls type.

Six foremen are employed on the 8-hour day-shift, namely, one for the sampling-mill, one outside, and one for each of the operating departments. However, the sampling-mill is run by two shifts daily, needing a foreman for each shift, while at night the roasters are run without a foreman. This makes a total of 19 foremen daily to take charge of 250 men. Early in 1917 the labor cost was close to \$1000 per day, or 40 cents per ton, while one man was needed for each nine tons of output; today all such expenses have greatly increased.

The blast-furnaces are 26 ft. 8 in. long by 44 in. wide at the tuyeres. In the middle of 1916, taking a whole month through, 635 tons was the daily output of each furnace; by the end of the year this amount was no better, being 580 tons per furnace. This figure is bound to vary according to the condition of the furnace and the charge. The furnaces are not shut-down for cleaning out, but are run down low, the crusts due to hot-top being burned out. Any adherent crusts are loosened by barring off. The difficulty, due to running a furnace with much over-fire, is that it overheats the furnace-top, the down-take and, in one instance at Anaconda, the dust-chamber and its contents were inflamed and damaged. With the Giroux hot-top this does not occur, since the large quantity of cold blast passing through the nested pipes in the closed top abstracts much heat, to say nothing of the aid furnished by the greatly heated blast in its action within the furnace. However, the crusts were burned off with so little difficulty that even barring down was seldom necessary. Variation in blast-furnace tonnage is due to variation in the physical condition of the charge. The total charge is made up of ore about 88%, with 6% each of limestone and of smelter cleanings or secondary material to be re-smelted. Per ton of charge, 6.5% of coke is used, and the furnace operates at 32-oz. air-pressure.

The blast-furnace charge is made up of (1) silicious ore, (2) iron ore, (3) converter ore, (4) oxidized ore, all new material, together with (5) limestone and (6) smelter cleanings, already mentioned. The silicious ore seems to be a misnomer, when we regard its composition. It contains Cu 5.2%; SiO_2 , 22.0; Fe, 25.0; S, 21.0; Al_2O_3 , 9.0; and CaO, 1.0%. It is thus named to contrast it with the iron ore containing Cu, 4.6%; SiO_2 , 8.0; Fe, 36.0; S, 39.0; and Al_2O_3 , 2.5%. Both these ores (1) and (2) are therefore sulphides. The converter ore (3) is

really the proper silicious ore, containing with 2.5% of copper some 70% of silica. The oxidized ore is silicious, but low in copper, carrying Cu, 1%; SiO_2 , 52; Fe, 21; and S, 2% only. These ores are combined in the charge in such proportions with limestone as to produce a slag of the following composition: Cu, 0.25%; SiO_2 , 34; FeO, 45; Al_2O_3 , 9; CaO, 4; and MgO, 2%; an iron slag low in lime. In the blast-furnace at least 75% of the sulphur is volatilized, leaving enough to form with the copper a matte of 18%, quite low for direct converting. It is, however, united in that operation with the reverberatory matte of 33% copper. There are eight men, including the foreman, per furnace-shift; one weigher weighing for the three furnaces.

The output of the seven 21-ft. Wedge roasters is 75 tons each daily, roasting down to 8.5% in the calcine. The raw charge, carrying 23% sulphur, averages 5.3% in copper. By calcining it loses 12% in weight. It is made up of silicious ore and iron ore, largely the former. One foreman and one helper per shift take care of the furnaces.

The two reverberatories, 19 by 100-ft. hearth-area, put through 350 tons daily. This consists of 210 tons of calcine, 70 of flue-dust, 10 of cleanings, and additions are made amounting to 70 tons more, for fettling. One notes the large amount of flue-dust from the blast-furnaces and some from the roasters, all of which can be successfully treated in the reverberatories. It can be imagined what difficulties would arise were there no reverberatory furnaces, and the poorer operation of the blast-furnaces were they compelled to re-smelt their own flue-dust. In such ease briquetting would most likely have to be resorted to, with its resultant additional expense of \$1 to \$1.50 per ton for this operation alone. In this department, including the foreman, nine men are employed; this includes the motorman and brakeman who supply the furnace and remove the matte and slag. For the output of 350 tons daily there are used 325 barrels of oil, being 0.92 bbl. per ton of charge smelted. Allowing a credit of 110 bbl. for steam produced at the waste-heat boilers, there is left 0.61 bbl. of oil per ton of charge. It is generally reckoned that of the total heat developed, but 35% is effective in melting the charge. In the middle of 1916 the fuel consumption was greater, being 1.08 bbl. per ton of charge, from which should be deducted 0.31 bbl. for steam developed.

We now come to the 12-ft. basic-lined converters, all five in operation. About two tons of converter ore, containing 70% silica per ton of blister copper (also called bullion) is produced. Fourteen tons of copper is yielded daily per converter, using 28 tons of converter ore to

flux the iron oxide produced in the converting. The converter ore also yields some copper, since it carries 2% of that metal.

As regards temperatures, it is of interest to note that in November the air temperatures for the month ranged between 65° and 38°, the lowest recorded being 24° F. Of converter-air 37,000,000 cu. ft. daily, reckoned on the displacement, was used to produce the 70 tons of copper, being 530,000 cu. ft. of free air per ton. This was supplied to the converters at a pressure of 14 lb. per sq. in. The air, per ton of furnace-charge, may be computed at 100,000 cu. ft., or for each furnace 40,000 cu. ft. of free air per minute. This is on the displacement basis, with no allowance for slips and consequently for the actual quantity of air delivered. Slip may easily be reckoned at 15%, being no greater for higher pressure. The air, on its way to the furnace, passes through pipes set in the furnace-top above the feed-floor. The invention is called the Giroux hot-top. The air thus flowing through these pipes and to the bustle-pipe rises between 200 and 300° F. When a fresh charge is introduced the temperature is lowered, so that the blast-air drops to 225°, while just before the addition the furnace-charge is glowing, due to the fire creeping up; then the air in the pipes rises some 50° more.

Chrome Ores in Pennsylvania

The War has increased so greatly the demand for chrome steel for use in making armor plate, projectiles, and high-speed tools that between 1914 and 1916 the domestic production was multiplied almost eightyfold. From the beginning of the chrome industry until the Civil War the mines of chrome ore in Maryland and Pennsylvania were practically the only sources of supply for the entire world. Up to the latter part of the nineteenth century almost all these mines were owned or operated by the Tyson Mining Co. of Baltimore, Md. When the importation of Turkish ores lowered the prices of chrome ore in the market of the United States the production of these mines was reduced, and the Pennsylvanian deposits were relegated to the position of a reserve supply. Since the Eastern mines were closed, about 1882, the chrome ore produced in the United States has been derived almost entirely from deposits on the Pacific Coast, and the output has been declining, while the imports, chiefly from South Africa and New Caledonia, have been steadily rising.

In November 1917, E. F. Bliss, of the U. S. Geological Survey, examined the chrome-bearing rocks of the so-called State-line serpentine belt of southern Pennsylvania. Chromite is reported to occur at intervals along the northern boundary of the area of serpentine that extends eastward from Bald Friar, on Susquehanna river, through the southern part of Lancaster and Chester counties, Pa., and the northern part of Cecil county, Md. The ore is found as massive compact chromite in nodules and pockets of variable size in a

serpentine gangue, and as a spotted ore in which grains of chromite are rather evenly distributed through the serpentine. The pockets that contain the massive ore are so irregularly distributed that prospecting is largely a matter of chance, but in view of the theory recently advanced that chromite is formed through segregation along the bottom or sides of an igneous intrusive mass, it is of practical significance to the prospector to note that most of the Pennsylvanian deposits lie along the north edge of an apparently southward-pitching mass of serpentine. Four of the old mines are on the contact of the serpentine and the crystalline schists.

Nine abandoned mines were examined. These extend from the old 'Line Pit', three miles east of Susquehanna river, on the Mason and Dixon line, for a distance of nine miles eastward. Four of the shafts, of which the deepest is at the Wood mine, long renowned as a collecting ground for rare minerals, disclose massive ore. Specimens from the Wood mine assay as high as 56% chromic oxide and average 48%. The remaining five mines show disseminated ore, known among the chrome miners of that region as 'birdseye.' In the prosperous days of the Eastern chrome industry this ore was apparently not considered sufficiently valuable to repay the cost of concentration. Now that the country is certain to be short of chrome ore the question whether low-grade ores can be profitably concentrated assumes new importance. At several old mines in Lancaster county and at three in Chester county there appears to be a fair grade of concentrating ore. At one mine about 2000 tons of disseminated ore is lying on the dumps, and rock taken a few feet below the surface about a mile east of the mine contains ore of the same character indicating a considerable quantity below the surface. Analyses of average samples from the dumps show 33.27 to 34.27% by weight of chromite in the ore. An analysis of the chromite concentrate from the samples shows 48.79% of iron and alumina and 51.21% of chromic oxide. The ore, which is non-magnetic, occurs in black grains of brilliant lustre. The gangue is a massive green serpentine that contains little or no asbestos.

In view of the geologic relations of the chromite deposits in this region and of the favorable market for the ore, the possibility of discovering and exploiting new deposits in southern Pennsylvania, as well as the practicability of working some of the old mine-dumps, should receive attention.

PORTLAND CEMENT specifications by the United States government established the following chemical limits, which shall not be exceeded:

	%
Loss on ignition	4.00
Insoluble residue	0.85
Sulphuric anhydride (SO ₃)	2.00
Magnesia (MgO)	5.00

The specific gravity shall be not less than 3.10, and the residue on a standard 200-mesh sieve shall not exceed 22% by weight.

REVIEW OF MINING

NEW YORK

**Silver.—Rocky Mountain Club.—Coal.—Standard Oil.—
Conscription of Wealth.—Publicity Copy.—Salt Pro-
duction.**

The silver situation is apparently more staple than has been supposed, and authorities both here and in Great Britain are satisfied with the present market price—about 92 cents per ounce. In the event of an unexpected appreciation in value the Government will probably take action by releasing part of the \$200,000,000 worth of metal now stored in the Treasury in the form of silver currency, but the melting of this will be delayed as long as there is no immediate necessity for price regulation. Government price-fixing at \$1 per ounce has been mooted, and leading silver producers are reported to be following the recent tactics of the farmers and storing their product in anticipation of a rise. Both China and India show enormous increases in exports during 1917, and a heavy demand from this quarter is expected in the near future.

The Rocky Mountain Club of New York numbers 1100 members, mostly mining men. Dues for town members are \$50 per annum, while out-of-town members pay \$25. The former are now urged to purchase \$500 worth of Liberty Bonds when the new issue is open for subscription, and to hand them over to the Club in lieu of dues for 10 years. Other members are asked to buy \$250 worth to cover their subscriptions for the same period. The interest accruing from the deposited bonds will go toward Club expenses and for patriotic purposes.

The Fuel Administration is apparently awakening to the fact that coal mined during the past winter was often of the poorest quality. There has been a concomitant price-fixing as owners with the choice of several mines have, in many instances, concentrated their output from low quality and accessible deposits. Inferior coal has been responsible for much of the distress during the past winter, resulting in delay and congestion. Even the movement of army transports and naval vessels have been hampered on this account. Governmental action may now compel the mining of clean coal.

The Standard Oil group has distributed \$26,483,747 in dividends during the current quarter. This exceeds any previous payment during a similar period subsequent to 1913 when the New Jersey company paid a special dividend of \$40,000,000, bringing the total to \$55,652,423.

The phrase "conscription of wealth" sounds formidable and ultra-socialistic, but the application of the idea is well within the bounds of possibility. The Income Tax is really nothing more than a conscription of wealth, and a compulsory war loan would be more favorably received in that the money would only be lent to the Government. New Zealand, the cradle of many notable reforms and a school of practical sociology, has passed a law compelling subscription to war loans by those in a position to do so. The details of the scheme show that there would be little serious objection to its adoption in other countries. The New Zealand government compels those whose incomes for the year ended March 31, 1916, were not less than \$2500

subscribe to war loans to an extent equivalent to three times their total amount of land and income tax (exclusive of excess profit duty) for which they are liable. The law further states that a taxpayer in this class who has already subscribed to an amount equal to 1½ times his tax liability, previous to the passage of the compulsory act, should be credited with that amount and his obligation reduced accordingly. This latter clause would indicate that those who had subscribed to a small extent only, and in disproportion to their income, would be obliged to subscribe the full legal maximum in addition to previous subscriptions.

Local opinion among journalists is almost unanimous in the opinion that the material emanating from the bureaus and committees at Washington, and disseminated broadcast by publicity agents, is almost valueless, and often duplicated to an extent suggesting an entire lack of co-ordination. It has been urged that real news-men should handle this work, that worthless copy should be eliminated, and the remainder submitted in a form permitting its publication without re-writing. At present a vast amount of time is spent in editorial offices in separating the occasional news item of value from the voluminous amount of valueless and ill-arranged copy that congests the mails and serves no useful purpose.

Total salt production in the United States during 1917 amounted to 6,946,000 short tons, an increase of 583,000 tons over the previous year. Of this total New York contributed 2,175,000 tons, a gain of 202,715 tons. This would have been greater but for labor troubles in certain districts. The State possesses exceptionally extensive rock-salt deposits distributed over 2000 square miles, mostly in Livingston county. They vary in thickness from 8 to over 300 ft. Ordinary coal or metal-mining methods are employed, and the product is broken and sized for the market. In some districts water is conveyed to the deposit through drill-holes, the brine pumped out and evaporated. Salt from solar evaporation is made in Onondaga county, but this method is being displaced by the use of vacuum-pan evaporation. Screened rock-salt is used extensively in the chemical industry, this accounting almost entirely for the large increase in production during recent years. It is a necessary product for the manufacture of caustic soda, sodium carbonate, sodium bi-carbonate, soda ash, salt cake, sodium chloride, sodium acetate, sodium phosphate, chlorine, hydrochloric acid, and other compounds. The refined salt for domestic uses is made by cleansing the coarse crystals, re-dissolving, sterilizing, filtering in vacuum or pressure-filters, and re-evaporating. The final product is then ground, dried, and screened for shipment.

CRIPPLE CREEK, COLORADO

Ajax Deep Work.—Lost Shoot in Vindicator Found.—Rich Ore in Dante.—Lease Notes.

Ajax mine's February production totaled 1850 tons, valued at \$37,000 gross. Since the Carolina company of Boston, operating under bond and lease, commenced operations, the shaft has been sunk from 1400 to 2000 ft. New orebodies have been opened at 1600 and 1800 ft., and prospects for ore on bottom level, where driving is in progress,

are considered good. Seven sets of sub-lessees are operating from above the 1200-ft. level, practically all working on ore. E. M. Rabb is superintendent.

An important discovery for the Vindicator company has been made by Hayes & Co., lessees operating on the 1100-ft. level of the main shaft. The lost Martin ore-shoot on the middle vein of the Vindicator system has been found. It had jumped across the dike, so to speak. So far the shoot is 27 ft. wide by cross-cutting, and as broken the coarse ore will average better than \$25 per ton. An initial shipment settled at \$25.60 per ton, while screenings carry up to 4 oz. gold. Dr. A. I. Hayes, prominent physician of this district, and the head of the District Hospital, with his partner Craig, has spent over \$5000 without return in search for the shoot, but now has one of the most profitable leases in the district.

In the Dante mine, on Bull hill, Fred Cobb has opened rich ore on the 600-ft. level. He is sub-leasing from the Big Toad Gold Mining & Milling Co., a lessee of the Dante Gold Mining Co. Cobb has opened a new shoot on the main Dante basalt vein, north. The core, a streak 2 to 6 in. wide of fluorite and quartz, shows calaverite assaying as high as 20 oz. gold per ton. The vein-matter is 4 ft. wide, worth nearly \$30 per ton exclusive of the rich streak.

The Victory Gold Mining Co. will this week take over the Elmer Smith lease at the Howard shaft, also five leasing blocks of the Mary McKinney Mining Co.'s Gold Hill estate. E. P. Arthur Jr. will have charge of operations. Extensive development is planned and shipments will continue from ore already available.

An air-pipe line was laid last week from the plant at the El Paso Gold King mine in Poverty gulch to the Shoo Fly mine, on Womack hill, owned by Stratton Cripple Creek Mining & Development Co., operated under lease by Oscar Simms & Co. of Cripple Creek. Machine-drills are now in use, and shipments will follow.

Settlement made for the second car of ore from the shoot recently opened on 900-ft. level of the W. P. H. mine on Ironclad hill was at the rate of \$50.40 per ton. The third shipment was loaded out last week. The property is owned by the United Gold Mines Co., and is operated under lease.

The Free Coinage Consolidated Mines Co. has commenced shipping from the Pinto mine of the Free Coinage Gold Mining Co. on Bull hill. Ore mined on the 450-ft. level, shipped to the Golden Cycle plant at Colorado Springs, is about 1-oz. grade.

Over 225,000 shares of Rose Nicol Gold Mining Co., believed owned by the estate of the late James F. Burns, were sold on the Colorado Springs Exchange last week. They realized \$3 to \$4c. The shares sold on March 14 at 15c., and on the 16th at 12c. in open market. The mine is under lease to the Camp Bird Mining, Leasing & Power Co. Ore has been cut at 800 ft. depth, also in the Roosevelt drainage-tunnel, cross-cutting the property at a depth of 2100 ft. Shares were selling about nine months ago at 4 cents.

The Dexter vein has been cut on the 800-ft. level of the Rose Nicol shaft, at a point 200 ft. south. The ore is 4 ft. between walls and will average \$30 per ton. The property is under lease to the Camp Bird Mining, Leasing & Power Co. for six years, beginning 15 months ago. Plans for a large ore-house—enough for six cars—is to be constructed, and an aerial tram will be built to carry ore to the loading-station in Eclipse gulch. Ore has also been exposed by the Roosevelt drainage-tunnel in the Rose Nicol at a depth of 2000 ft. This vein is to be developed by drift from the tunnel-level. Ore will be taken out through the Elkton shaft, connecting with the tunnel.

The Howard shaft and five leasing blocks of the Mary McKinney Mining Co.'s estate on Gold hill was taken over last week by the Victory Gold Mining Co., represented by

E. P. Arthur Jr. The lease was recently purchased from Elmer Smith of Cripple Creek, who had operated the mine continuously for 12 years past, and made a fortune. Smith ceased operating when one of his miners was killed in the mine about three months ago.

The Modoc Consolidated Mines Co. is raising from the 15th level of the old incline to connect with the new vertical Frankenberg shaft on the Modoc mine. Shipments will commence from the filled stope as soon as the connection is made. The incline workings will then be thrown open to lease.

The Clyde shaft of the Millasier Mines Corporation has been sunk to a depth of 1425 ft. The station at 1400-ft. level is now being timbered preparatory to development.

The Forest Queen Mines Co. has been incorporated to take over and operate the Gaylord lease on the Forest Queen mine on Ironclad hill. Officers and directors are Robert A. Sullivan, Denver, president; Edwin Gaylord, Cripple Creek, vice-president and general manager; and John H. Reddin, Denver, secretary and treasurer. The new company is producing steadily from two orebodies under development on the 650-ft. level. The Forest Queen is owned by Los Angeles and Southern people.

The estate of the late James F. Burns, founder of the Portland company, and for many years its president, has been valued officially at \$1,251,871. The amount to be paid by the estate to the State as an inheritance tax will be \$44,379. By the will the estate was divided equally between the widow and two children. John H. Nichols, superintendent for the Camp Bird Mining, Leasing & Power Co., has been elected a director of the Mary McKinney Mining Co., representing the Burns interests. Mr. Nichols will in September have charge of the mining interests of the Burns estate.

The Excelsior Mining, Leasing & Electric Co., lessee at the Longfellow claims of Stratton estate on Bull hill, has cut a vein 48 in. wide, 17 in. of which assays 3 oz. per ton. This is supposed to be Legal Tender vein of the Golden Cycle system.

ELY, NEVADA

Labor Troubles Settled; Cause of the Walk-Out.

Labor troubles of the Nevada Consolidated Copper Co. have been settled for the time being. The men returned to work on the morning of the 26th. The Governor, Emmet D. Boyle, and State Labor Commissioner, Mr. Cole, came here and persuaded the men to resume work. The Governor has agreed to try to have Secretary Wilson of the Federal Labor Department at Washington, D. C., send a mediator, who will organize a State labor board to settle these questions during the War. The tie-up came about by firemen in the open-pit demanding a 50c. advance within 24 hours, or a walk-out. They went out, about 30 of them; not as a union, but independently. Then the enginemmen and switchmen joined them, making 90 in all, thus throwing out of employment most of the company's men, between 2500 and 3000. The Ruth mine continued producing 3500 to 3850 tons daily from the underground workings. Of the thirty who went out first, not one had been on the company's payroll for six months. It is doubtful if there is a mining company in the United States which treats its men better. They are only charged \$25 per month for board, room, light, and heat; the table alone costs the company \$32.50 per month per man. There never has been a complaint against the board. The wage-scale of the class that went out is better than any other large copper company excepting at Bisbee, where they receive 10c. more per day. Condition of the roads has improved, and manganese shipments have been resumed.

TORONTO, ONTARIO

Improvements on Canadian Railroads.—Porcupine, Cobalt, and Other Districts.

The Canadian government is taking steps to put the main railroads in good condition. For some time renewals of rails have been badly needed, but have been postponed, owing to the difficulty in procuring them. The Government has placed a contract for 100,000 tons of 80-lb. steel rails with the Dominion Iron & Steel Co. of Sydney, Nova Scotia, to be delivered by the end of July. It has also secured 500 miles of light rails made in the United States for the Russian government. The heavy rails on some sidings and branch lines, and on the Hudson Bay railway now under construction, will be taken up, and lighter rails substituted. The heavy rails will be used for much needed replacements on the Government lines, and the Canadian Northern. The Canadian Pacific and Grand Trunk will be supplied with rails at cost, plus transportation charges. The rolling-stock of the Government roads, including the Canadian Northern, will be replenished by giving contracts for 150 locomotives and 7500 cars, tenders for which are now under consideration. The prices asked, however, are so high that, before letting the contracts, an investigation is being made to ascertain whether the details entering into the cost of manufacture justify the increase. Should the contemplated plans be fully carried out, the expenditure will approximate \$40,000,000.

Cobalt.—La Rose Consolidated has prospects of a new lease of life, owing to an important discovery in the Violet mine. Here the shaft is down 425 ft. A cross-cut on the 410-ft. level cut three veins of good width and mineralization in the Keewatin zone immediately below the diabase. It is considered probable that this may be a continuation of the vein system that has yielded considerable silver in the O'Brien adjoining.

The new shares of the Adanac numbering 228,000 have been taken up by the shareholders at 10c. per share.

Fort Matatchewan.—A road is being constructed from Elk lake to this new gold district. Supplies are going in to the Otisse property, where buildings are being erected. A small prospecting plant will be installed. The Craig property is also to be thoroughly explored. The district is likely to be the scene of much development as soon as the season permits.

Munro Township.—The Croesus mine and mill have been closed until after the War, owing to the high cost of operating. The mine has produced some rich ore, but expenses were considerably increased by flooding, and the management considers that loss of interest caused by the suspension will be more than offset by reduction in price of materials and labor later on.

Porcupine.—The labor situation is much better. There has lately been a considerable influx of men, as work is likely to be resumed soon on properties where operations were either suspended or much curtailed by reason of shortage of labor.

The Dome Mines Co. is developing an orebody 120 ft. wide, said to average \$17 per ton on the 800-ft. level. Milling will not be resumed until enough of this grade is available to keep the plant busy. Under present conditions, it has been found impossible to treat \$5 ore profitably. Sinking the main shaft to 1500 ft. is believed will open a large body of good milling ore.

At the Dome Lake mill an Oliver filter has increased capacity to 150 tons daily.

Most of the new equipment of the Hollinger mill has been tested and found to be satisfactory. Production is maintained, and resumption of dividends is likely at an early date.

ST. JOHNS, NEWFOUNDLAND

Twillingate.—The Great Northern Copper Co. operating chalcopryite mines almost at the water's edge, has made arrangements for the erection of a small experimental mill and concentrator here. Results will decide definite plans for larger units to be erected later on. The company is said to have extensive ore-reserves and possess exceptional facilities for loading, and cheap transport to and from United States Atlantic ports, although this is restricted during the winter on account of the severity of the weather. The company also possesses the exceptional advantage of being outside autocratic dominance in flotation work by the Minerals Separation company. The milling tests will probably in-

MAP OF NEWFOUNDLAND

clude the use of sea-water and fish-oil. An abundance of the latter can be obtained cheaply, and the results of the tests should prove of general interest. The recent discovery of an oil-well at Bell island is an incentive to optimistic forecasts with regard to the fuel situation.

Fish-oils exported from this Dominion to the United States in 1917 and 1916 were as follows:

Kind	1917		1916	
	Quantity	Value	Quantity	Value
Cod, crude, gal.	1,837,652	\$1,231,907	700,517	\$493,640
Cod, liver, gal.	130,972	309,505	158,032	322,700
Seal, gal.	358,088	403,066	574,171	474,447

The above figures will give an idea of the fish-oil available for flotation purposes, which could probably be increased if mining operations expanded.

VICTORIA, BRITISH COLUMBIA

Institute Meetings at Montreal; Probable Outcome of Discussion

Representative mining men of Canada gathered at Montreal, Quebec, from March 5 to 9. Several organizations held important meetings, the largest numerically being the Canadian Mining Institute. There were also sessions of two special bodies, namely, the Munitions Resources Commission and the Advisory Council of Scientific and Industrial Research, the latter acting in an advisory capacity to the Dominion government. W. Fleet Robertson, Provincial Mineralogist, was present at all of these meetings on behalf of British Columbia and, since his return, has had several conferences with the Hon. William Sloan, Minister of Mines. While he is not prepared to make any statement as yet as

to what was accomplished or decided upon, he asserts that policies were tentatively agreed upon which may be expected to lead to development of some of the rarer minerals of British Columbia for war purposes. At both the Research and Munitions Commissions there were in attendance representatives from the three other mineral-producing provinces of the Dominion—New Brunswick, Nova Scotia, and Ontario. That something may be expected in the more intensive exploitation of the resources of the Provinces, more especially in molybdenum and manganese, was intimated by Mr. Robertson. At the Canadian Mining Institute meeting one of the outstanding subjects considered was that of fuel production in Canada. In this connection the absolute dependence of Ontario on coal from the United States for domestic and industrial purposes was emphasized. It was felt that some action should be taken, and the decision was reached that the situation might be met by the development of the peat in the Province. That there was a large quantity of this fuel in Ontario, and that it might be produced in briquette or powder form in sufficient quantity to make the Province at least less dependent on importations was the consensus of opinion. An interesting paper was contributed by W. A. Carlyle, former British Columbian Mineralogist, later manager of the War Eagle mine, Rossland, B. C.; and more recently employed in Spain. It took the form of an illustrated talk on the Rio Tinto copper mines of Spain, where 15,000 men are employed and ore has been blocked out that is calculated to last more than a century. Members of the Institute visited the Armstrong-Whitworth Works at Longueuil, Quebec, to see the electric-steel furnaces in operation, making steel for high-explosive shells, also the higher grades of tool-steel. This is a manufacturing art which the same company has carried to great perfection in Great Britain. Mr. Robertson spent three days at Ottawa on his return, visiting the Dominion Geological and Mining Departments, also attending a special meeting of the Geographic Branch.

JUNEAU, ALASKA

Alaska Juneau Company's Mine and Mill.

F. W. Bradley, president of the Alaska Juneau Gold Mining Co., has issued the following statement to the shareholders, with the annual report:

The company's new mill has been in combined process of completion and operation since March 31, 1917, and the best it has so far been made to accomplish is less than one-half of its promised capacity, at an operating cost per ton of over twice the expected cost. By installing machinery for an additional stage of crushing, the capacity of the mill can be increased, and by making other costly additions to and changes in the mill it would be possible to reduce the present high operating costs; but the real problem has been to keep as much waste as possible out of the fine-grinding end of the mill-work. It is estimated that two-thirds of the feed to the mill has been straight waste, and that the cost of fine grinding it is greater than the cost of fine-grinding ore.

The new mill was designed with the plan in view of both 'wholesale' mining and 'wholesale' milling; but as the layout of the pre-mining work has resulted in a caved mixture of an undue proportion of waste with ore, the wholesale plan of milling what has turned out to be (as far as the original pre-mining caving system is concerned) an uncontrolled mixture of waste and ore has had to be abandoned as unprofitable. Therefore in order to operate at a profit, the mine and mill operations are being re-adjusted to the 'sorting' plan of working which was interrupted nearly three years ago when the 'wholesale' plan was decided upon.

The payable values in the vein are carried by quartz string-

ers that, as so far developed in the Alaska Juneau property, have averaged about \$6 in gold per ton, in addition to their lead and silver values, and are susceptible of being partly sorted out from their enclosing vein-matter. This is not only because of the marked difference in color between the quartz and vein-matter, but because the quartz is much more friable than the vein-matter and thus lends itself to a partial mechanical separation, both when mined and when subjected to coarse crushing in the mill. Monthly crushings of several thousand tons each during the 16 years' operation of the old 30-stamp mill have given free-gold yields varying from a minimum of 35c. for low-grade vein-matter up to a maximum of \$6.21 for sorted-out quartz. In addition to its recoverable gold, the ore also carries recoverable lead and silver values. Many milling-tests in the old 30-stamp mill on ore sorted from the surface workings in the vein, and also milling tests in the pilot mill on ore sorted from the deepest workings in the vein have given recoveries of over \$5 free gold per ton from all the ore so sorted. During the first six months of 1915, 23,286 tons of mixed sorted quartz and vein-matter made an average mill-feed for the pilot mill of \$3.22 gold assay-value per ton. The sorted ore thus milled was obtained by mining three tons of vein-matter, of which two tons were left in the stopes as waste-filling and the remaining ton of about equal portions of sorted quartz and vein-matter was sent out of the mine as mill-feed. Because the pre-mining system as carried out has left no control over the quantity of waste mixed with ore, the mill-feed for the new mill during 1917 has averaged a gold assay-value of \$7.5c., or 3.74c. less than the gold assay-value of the mill-feed to the pilot mill for the year 1916. This lack of control has resulted in sending such a large proportion of waste with ore to the mill that of the rock over 12 inches in size fed to the mill, probably 90% has been straight waste, as distinguished from low-grade vein-matter.

To overcome this waste dilution and thus place the property on a profit-earning basis, an installation is being made, as outlined in the accompanying report of the general superintendent, to mechanically reject as much coarse waste as possible between the Blake and gyratory crushers. Also a new stope is being opened on another section of the vein where physical conditions promise a dilution of less waste with the ore and consequently a higher grade of feed for the mill. Up to March 10 this new stope had been cut out in vein-matter for an area of 25,482 sq. ft., with an average gold assay-value for that area of \$1.56 per ton.

SILVERTON, COLORADO

Recent Activities in the District.

The Sunnyside tram is almost complete and the new mill is ready to begin the season's run. It is expected to produce over 1000 tons of concentrate per month. It is probable that this mine will be rated as one of the largest, if not the largest, producers in the district. The mine is under the management of M. M. Kuryla. The company has been making conditions agreeable for employees, in the matter of recreation and welfare work, and all seem to be satisfied. Labor shortage is not expected during the coming season.

The D. L. & W. Mining & Reduction Co., managed by H. M. Kingsley, and financed by Iowa capital, is now working at full capacity, employing over 20 men. A tram has been built over a distance of 3000 ft., leading to a siding on the Silverton Northern line, thus saving packing ore down the mountain-side. A mill will probably be erected by the company along the Animas river. The company's future appears to be good. The Crater mine, above Animas Forks, is another property that will be operated by this company during 1918.

THE MINING SUMMARY

ALASKA

Fairbanks.—Eighteen miles east of this place is the Stepovitch tungsten mine. In 'Economic Geology' for March the property is briefly described by Alan M. Bateman. The deposit occurs within Birch Creek schists, which consist of crystalline limestone and mica-schist. Ore appears to be a replacement and impregnation of the limestone along its contact with the mica-schist. It occurs as small shoots within the limestone. One shoot is 4 to 60 in. wide, the other 12 to 72 in. wide. Operations have been of a haphazard nature. Depth opened is 50 ft. on incline. One shipment of 265 tons has been made.

ARIZONA

Globe.—Old Dominion company last week exploded 25 tons of Hercules dynamite, breaking 300,000 tons of limestone. This is used as flux in smelting. W. G. McBride, general manager, states that this was the second largest blast ever set off in Arizona, one at Ray being bigger. In the news last week we mentioned a large blast at Ajo, whereby 200,000 tons of ore was broken.

Jerome.—General Development Co. has suspended work at Jerome Copper Co.'s property after doing 1750 ft. of work. Resumption is dependent, it is said, upon developments in the Green Monster.

Mammoth.—W. R. Ramsdell and associates have purchased the molybdenite property of E. W. Childs at Copper Creek. A large body of molybdenite is blocked out, containing 2% MoS₂. This property has been held by various interests, but because of small copper content has been given up. It is claimed that metallurgical difficulties are now overcome.

Mayer.—Consolidated Arizona company's Blue Bell mine has opened two new orebodies, one on 800-ft. and the other on 1200-ft. level. The latter level will soon be yielding 150 tons daily. A drift on 800-ft. level is to be driven south to open the Blue Thunder shoot 2200 ft. from main shaft.

Metcalf.—Shannon Copper Co. may curtail operations on account of decrease in value of ore. At Clifton, the company will continue to concentrate and leach 15 tons of ore daily, extracting 14 to 16 lb. of copper per ton at cost of 12c. per pound. N. L. Amster is president.

Miami.—Miami Copper Co. is reported as preparing plans for increasing capacity of its 6000-ton mill.

Tombstone.—Bunker Hill silver mine, owned by Phelps-Dodge Corporation, was closed last week on account of low grade of ore. Manganese has been mined during the past 6 months. Lessees will continue to work.

Tucson.—No. 2 shaft being sunk by San Xavier Extension has cut some ore that was found on 275-ft. level of prospecting shaft 150 ft. north.

Alpha Copper Co.'s work on 200-ft. level proved that two outcropping veins have junctioned into one body 25 ft. wide of high-grade lead-silver-copper ore.

Reinger-Freeman company, operating in San Xavier district, has found a new silver-gold vein in main shaft, which

is 208 ft. deep. Work has been started on San Carlos claims of this company.

CALIFORNIA

Alleghany.—Second trial of the suit of Senator William Flinn of Pittsburgh, Pennsylvania, against the Twenty-One Mining Co. is being held before Judge Thomas F. Graham in San Francisco. In 1913 Flinn agreed to purchase the mine for \$250,000. He paid down \$25,000. When he started to work the mine he alleged that the ore was not equal in value to samples and that the mine had been salted. Judge Graham gave him a judgment. Soon after the Twenty-One company resumed possession of the mine the company extracted gold worth \$125,000, having found a shoot. Then the Twenty-One asked for a new trial, holding that Flinn's contention that the mine had been salted was not justified. This question is to be decided by Judge Graham. Further complications entered the case when the Supreme Court gave a decision recently, holding that the Sixteen-to-One mine is entitled to the high-grade ore mined by the Twenty-One company on the ground that this ore was taken from the Sixteen-to-One.

Crescent Mills.—Juneday Mining & Milling Co., operating at this place in Plumas county, has put up a good deal of machinery, expects to construct a power-line this spring, and will erect a 50-ton mill during the summer.

Downieville.—To impound debris from hydraulic mines at Brandy City, a concrete dam is to be constructed across the North Yuba river at Bullard's Bar. G. E. Taylor is manager.

Forest.—Kate Hardy Mining Co. has received permission from State Corporation Commission to issue, in addition to directors' qualifying shares, 250,000 shares to the San Jose Realty Co. in consideration for a lease and an option to purchase the property. The company is also authorized to sell 250,000 shares at 25c. per share, so as to net 80% of the selling price.

Kennett.—Wage dispute at the Kennett smelter, between the Mammoth Copper Co. and its 300 blacksmiths, smeltermen, electricians, zinc-plant workers, and machinists was to be adjusted in San Francisco on March 30 by the Federal Wage Commission. Company and men have agreed to abide by the Commission's ruling. The tradesmen urged that they should receive the same pay as men similarly employed in shipyards around San Francisco, but the company holds that it cannot afford to pay such wages.

Needles.—Rincon Mining & Milling Co., having claims in the Monumental mining district of San Bernardino county, has been given authority by the State Corporation Commission to issue 1250 shares to Walter J. Farr, H. W. McDowell, and J. C. McDowell in exchange for four groups of claims on the Colorado river, together with machinery, improvements, and equipment thereon. Company is also authorized to sell 250 shares at \$50 per share for cash, so as to net the full selling price.

Silver Lake.—Vanderer Mining Co., with 13 claims in San Bernardino county, has received permission from the

State Corporation Commission to sell 4950 shares at 20c. per share, and 60,000 shares at 60c., so as to net 80% of the selling price. All of the claims have been worked previously. The company proposes to re-open the lower adit.

COLORADO

Boulder.—Metal Mining Association's annual dinner here recently was largely attended. The Association is considered to be doing good work.

James Duce, State Oil Inspector, is to make an examination of petroleum resources of Boulder county.

Lucky Two mines, between middle and north Boulder creeks, has been acquired from the W. B. Holmes estate by W. F. Blecher of Boulder. Property is a large producer, and is to be extensively developed.

Nederland.—La Plaisance M. & M. Co. has been incorporated by E. V. Grant, F. A. Fair, and Alfred Dawson to operate the La Plaisance with the New England mine. Former was a large producer of gold and silver years ago. Machinery is to be ordered.

Ouray.—Silver Point Mines Co. has been organized with capital of \$50,000. A. E. Bundson of Denver is president. Mine was a good producer of silver ore about 15 years ago. It is just south of Bear creek. The lower adit is being reopened.

Prospectors are preparing for exploration of the Cow Creek district, following discovery of molybdenite there last fall.

Rico.—Rico Argentine company last week had 1000 tons of lead and lead-zinc ores awaiting improvement in roads.

IDAHO

Kellogg.—J. P. Acoam of Spokane and associates have concluded purchase for \$80,000 of controlling interest in property of Sidney Mining Co. in Pine Creek district. The property includes 18 claims, covering 350 acres.

Mullan.—Federal Mining & Smelting Co., during quarter ended January 31, made a loss of \$193,525, compared with a profit of \$359,929 in the previous period. Shipments included 12,036 tons of ore and concentrate, against 32,659 tons.

Copper King has opened ore 50 ft. wide for a distance of 75 ft. Ten feet on hanging wall assays 3.3% copper and 17 oz. silver per ton. Remainder assays 4 to 6% lead and 5 oz. silver. Ore is in Revett quartzite. A 200-ton mill is proposed later on. H. W. Ingalls is manager.

Paris.—Western Phosphate M. & Mfg. Co. is to erect a 100-ton plant to crush phosphate rock. Deposit is said to be 150 ft. wide, with two strata, 6 and 10 ft. thick, carrying 73 to 78% tri-calcium phosphate. The crushed rock is applied directly to soil as a fertilizer. Lewis A. Jeffs, of Salt Lake City, is general manager. Shipments to Pacific Coast points have been maintained since October last.

Sagle.—Armstead Mines Co., operating on Pend Oreille lake, H. H. Armstead president, has secured \$200,000 for erection of development and 100-ton mill. O. B. Hofstrand of Salt Lake City has designed the plant. Ore carries silver mostly, with some gold and copper.

Wallace.—Coeur d'Alene region in 1917 produced the following metals, according to Robert N. Bell, State Mine Inspector:

Lead, pounds	395,883,000
Zinc, pounds	96,123,000
Silver, ounces	12,497,917
Copper, pounds	7,282,000
Gold, ounces	41,326

Wardner.—Lookout Mountain M. & M. Co. has been financed by M. Baumgartner of Spokane. About \$10,000 is

to be spent on compressor, machine-drills, and extending the adit. Property is on Pine creek. Ore carries lead and silver.

KANSAS

Baxter Springs.—Inspiration company, 7 miles west, is operating its 400-ton mill 10 hours daily. Ore carries 7% blende, and concentrate 50% zinc and 50% lead. Shafts are 250 ft. deep. B. E. Brown is general superintendent for the controller, Fred Hutting.

MICHIGAN

Houghton.—Ahmeek Mining Co. pays \$2 per share on April 10. Mine is producing 5000 tons of ore daily.

Osceola Consolidated pays \$2 per share on April 30. This makes \$4 for current year.

Seneca Copper Co.'s shaft has cut the Osceola lode. Some of the ore carries rich 'shot' copper. Lode is in two parts, hanging-wall side being 9 ft. wide.

Mohawk is to use four electric locomotives in No. 6 shaft, if they can be secured.

Coal docks of Calumet & Hecla have been burning for over two weeks. More than 100,000 tons of coal is stored there.

Mayflower-Old Colony Copper Co.'s initial report for 8 months ended December 31, 1917, show balance of cash assets amounting to \$32,302, against \$103,596 on May 1. Main shaft is 261 ft. deep. Sinking by bucket is to be superseeded by skip.

Indiana company has suspended work indefinitely due to lack of funds. Little has been done for some time.

Mass Consolidated Mining Co. in 1917 crused 244,671 tons of ore averaging 16.29 lb. per ton, yielding a total of 3,984,616 lb. In 1916 the figures were 287,900 tons, 16.51 lb., and 4,752,588 lb., respectively.

Iron Mountain.—Aragon mine, one of the Oliver properties, situated at Norway, will be electrically operated as far as possible. Plant will include pumps, underground haulage, hoisting, etc., and is on the way. Power will come from hydro-electric plant at Quinnesec Falls.

At Traders mine of Antoine Ore Co. new electric machinery, including two pumps and compressor, are being installed. Electric haulage was started last fall. Compressor capacity is 1200 cu. ft. Pumps will handle 600 gal. per minute each. Normal inflow is 200 gallons.

MISSOURI

Damsel.—Osage Mining Co.'s property in Camden county was examined in October last by F. E. Small, the following being abstracted therefrom: Deepest shaft is down 75 ft. Several others have been sunk, also several adits driven. All openings are said to show ore carrying lead, gold, silver, copper, and zinc. Drill-holes from 70 to 200 ft. deep also show ore. Production so far has been 500,000 lb. of lead ore. A 1000-ft. shaft is suggested to follow one of the drill-holes. Cost of mining and milling is estimated at \$1.50 per ton.

Galena.—Drill-hole put down by L. H. Phillips of Joplin on leased land shows the following record:

Depth, ft.	Blende, %
230 to 235	9.68
235 to 240	7.60
240 to 245	23.98
245 to 250	10.43
250 to 252½	11.17
252½ to 255	17.00
255 to 260	19.81
260 to 267½	30.10
267½ to 272½	57.81
272½ to 275	26.82
275 to 280	5.36

Joplin.—Zinc-ore market was weaker last week. Production of Missouri-Oklahoma-Kansas region was 9577 tons blende, 175 tons calamine, and 1697 tons lead, averaging \$48, \$35, and \$85 per ton, respectively. Total value was \$513,231, making \$5,750,308 for 12 weeks. Oklahoma contributed \$444,349 of last week's total.

MONTANA

Butte.—Davis-Daly Copper Co. reports as follows for last quarter of 1917:

Development, feet	1,934
Ore shipped, tons	11,891
Copper, pounds	1,773,701
Silver, ounces	76,498
Revenue	\$364,392
Disbursements	219,919

Cash at end of year amounted to \$105,048, and quick assets \$129,812.

Tuolumne Copper Mining Co. during 1917 shipped 30,972 tons of ore, averaging 2.431% copper, 1.471 oz. silver, and 0.0072 oz. gold per ton. This was mined on 1200, 1400, and 2600-ft. levels. On account of high costs, operations at the Tuolumne mine were suspended at beginning of 1918. Net smelter return was \$200,303. Main Range mine produced 10,967 tons, assaying 1.972% copper, 9.422 oz. silver, and 0.0078 oz. gold. This came from 700 stope on Spread Delight vein. Shaft is being sunk to 800 ft. Net smelter return was \$106,703. At Colusa-Leonard Extension mine development is under way at 1600 ft. New machinery was installed. Main Range company will soon be directly controlled by Tuolumne. Paul A. Gow is manager of all properties.

Helena.—Thomas Cruse Developing Co. has installed a new air-operated hoist on the 640-ft. level. A winze is being sunk on vein which carries good gold-silver-lead ore.

A 75-ton concentrating mill is being built at the Economy mine, East Helena. About 125,000 ft. of lumber will be required. The mine is developed 300 ft. deep.

Iron Mountain.—Intermountain Copper company shipped 2 cars of ore and 8 cars of concentrate during March. Crude ore averaged \$1200 net per car, and concentrate \$2200. Recent development revealed 30,000 tons of ore between 200 and 400-ft. levels, east of two faults. In the plant a ball-mill and Wilfley table have been added, raising capacity to 125 tons daily.

NEVADA

Aurum.—Spring Valley Copper Mines Co. has been organized by G. E. Hemphill and others of Utah to operate in the Nuncy district. Good copper-silver and silver-lead-copper ore has been opened.

Goodsprings.—Yellow Pine Mining Co. reports for January 1956 tons of concentrate and ore returned \$57,579 gross. Expenditure was \$16,804, leaving \$40,774 profit. Mill was closed at end of month. In February, 1475 tons of crude zinc-lead, 115 tons of zinc, and 50 tons of lead ore was shipped; but no returns are available yet. A new crushing and sorting plant was installed for crude ore. The 700 north orebody yields most of the ore, but new shoot on 300 sub-level is becoming important.

Omco.—Olympic Mines Co. in two years has transformed this place from a sage-brush patch into a thriving little centre with post-office and daily mail service. Omco is 25 miles north-east of Mina, in Mineral county, the nearest rail point. The 100-ton mill and cyanide plant has just completed a satisfactory year's run. During this period ore averaged \$18 gold per ton. Extraction was 96 to 97%. Machinery includes a Joshua Hendy ball and tube-mill, Dorr duplex classifier, thickeners, and agitators, Oliver filters, and Merrill apparatus for zinc-dust precipitation. On March

19, the Governor, ex-Governor, and other prominent Nevadans visited the property. The men were addressed concerning their position as Americans in the present strife. A branch of the Red Cross has been established at Omco. Every member of the community is identified with the movement, and most of the men contribute one day's pay per month. Fred J. Siebert is general manager and J. O. Greenan superintendent.

Pioche. In the suit between Virginia-Louise and Prince Consolidated, in which the former was awarded \$27,334,

MAP SHOWING LOCATION OF GOLD MOUNTAIN DISTRICT, NEVADA

and costs about \$3000, the plaintiff could not collect, as the defendant also had an apex suit against Virginia-Louise, which was not settled. Virginia-Louise retaliated by asking the Nevada Railroad Commission to declare the railroad of the Prince company a common carrier and force it to carry Louise ores. The dispute has been settled, judgment against the Prince is canceled, and the apex suit and the common carrier case are to be dropped. The Prince has agreed to haul the Virginia-Louise ores over its railroad. The transportation agreement covers a period of five years.

Tonopah.—Ore production of district last week was 10,972 tons, valued at \$183,464.

Tonopah Extension in February extracted 835 oz. gold

and 82,882 oz. silver from 7927 tons of ore, realizing a profit of \$16,584.

Apex suit between Jim Butler and West End was argued before U. S. Supreme Court at Washington on March 27. No decision is expected before June.

Interest increases in the Gold Mountain district, and development expands. The Tonopah & Goldfield Railroad may construct a spur from its main line into the district. Tonopah Divide shares have sagged from \$2 to \$1.75. Last week the drift on the 270-foot level was advanced 47 feet in good ore. A compressor and hoist are being installed. —Tonopah Gold Zone Mining Co. has been re-organized as Gold Zone Divide Mining Co. Old 300-ft. shaft is to be repaired. —Divide Extension has been provided with a hoist and compressor. So has the Dividend mine, where sinking is in progress. —In the Gold Reef district, near Gold Mountain, the Gold Wedge property is said to be a good prospect.

NEW MEXICO

Hanover.—Republic Mining & Milling Co. is shipping high-grade zinc ore to smelters in Pennsylvania. Report for period October 1, 1916, to January 1, 1918, shows that receipts totaled \$41,467, of which \$31,748 was from sale of shares, \$9000 from notes payable, and \$719 from iron and lead ore. Equipment and development cost \$29,438, and purchase of property \$5500. Estimates of developed ore in both groups total 75,000 tons, assaying 19% zinc. To depth of 200 ft. there was 970 ft. of work done by the present owners. When 100,000 tons are opened, a 100-ton mill is to be built.

OKLAHOMA

Commerce.—Consolidated Zinc & Smelting Co. has acquired the Emma Gordon and other tracts here. Some of them are well developed, with mills in operation. J. D. Hawthorne is superintendent.

Picher.—Production of the region last week was 7254 tons blende and 1129 tons lead, valued at \$444,349.

Big Chief Mining Co.'s property—40 acres and 250-ton mill—was sold last week for \$150,000 to Oklahoma City and Wayne people, represented by J. M. Curtis.

Quapaw.—Imperial Development, St. Louis Lead & Zinc, Big Three, and Muskogee Lead & Zinc companies have combined to fight the water problem. A 10-in. Texas pump is to be put in the Muskogee, just east of Imperial, which already has two 12-in. and one 14-in. Pomona pumps, and another Texas pump. Water was encountered at 167 ft. in the Imperial. Shaft was cemented and 200 ft. was attained, but driving could not be done on account of water. Rich ore was opened during this work. J. C. Isbell is manager and G. O. Spafford superintendent.

Tar River.—Standard Lead & Zinc Co. has sold its property and 250-ton mill to Fort Worth, Texas, people, for \$250,000. J. D. Young and others are interested.

OREGON

Grants Pass.—Mountain Lion gold mine, 12 miles southwest of Grants Pass, has been acquired by J. P. Sinnott of Portland and C. G. Murphy of Grants Pass. They have erected a 30-ton Lane mill. This mine has been extensively opened during the past 25 years, there being 8000 ft. of workings done on two veins that are in greenstone and slate, and close to contact of these rocks within an area of granodiorite. The slate occurs as narrow lenses in the greenstone and the best ore of the veins has been obtained near the contact of the two rocks. The veins are 12 in. wide and are faulted at many places. The vein filling consists chiefly of quartz, calcite, and sulphides, the last constituting 1%. The new equipment is driven by gasoline power.

Takilma.—Golconda chrome mine, six miles north-east of Takilma, has made an initial shipment of two cars of ore at Water creek under the new lessee, R. J. Rowen. Thirty-five miners are employed, and on arrival full equipment of auto-trucks ordered, production will be 1200 tons of ore per month.

TENNESSEE

Manganese deposits of Bradley county are briefly described in 'Resources of Tennessee' by the late A. H. Purdue, State Geologist. In 1916 a new deposit was opened 9 miles south of Cleveland, and another in 1917, two miles away. Manganese occurs in limestone and residual soil above it. Layers of the mineral vary up to 14 in. thick. Ore is said to be high grade, and is found in caverns in the lime and in the clay. Some boulders weigh 800 lb. Present operators expect to get one ton of manganese from each 100 tons of residual material. Immediate source of the mineral is Tellico sandstone.

TEXAS

Abilene.—Rich copper ore has been discovered on ranch of James Billberry, near here. For several hundred feet the deposit is 7 ft. thick. Native copper is found scattered over a wide area north and east of Abilene, and geologists think that it has come from this deposit. C. S. Brown of Post and L. A. Harrison of Jayton, Texas, have obtained a lease on the property and are preparing to begin extensive development.

Diamond Mound.—Texas Exploration Co., holding 5200 acres near here, is to construct a large sulphur plant, using the Frasch process of extraction from the beds. E. F. Sills, H. T. Staiti, and George Hamman of Houston are largely interested.

Quanah.—T. Sanford Gibbs will erect a mill at his copper mine situated near this place.

UTAH

Alta.—Cardiff Mining Co. has 12 ft. of \$159 ore on 800-ft. level. It carries 9.1% copper, 26.6% lead, and 117.4 oz. silver per ton, also desirable quantities of iron. About 250 tons has already been broken. Bins at mouth of south fork are full of ore, also on dumps, totaling 3000 tons. This is valued at \$40 per ton. When roads permit, over 200 tons daily will be shipped.

Bingham.—Bingham Mines Co. paid 50c. per share on April 1. This is equal to \$75,000, making \$337,500 to date. Net receipts of company's properties during past two years were as under:

Mine	1917	1916
Dalton & Lark.....	\$174,501	\$132,537
Commercial	1,758	1,461
Victoria	2,755
Victoria Con.	146,753	37,893
Eagle & Blue Bell.....	498,677	136,126

Yosemite showed a loss of \$12,918, against a loss of \$5646 in 1916.

Park City.—Silver King Consolidated Mining Co. reports the following for 11 months of 1917 compared with the whole of 1916:

	1917	1916
Ore, tons	10,260	10,082
Gold, ounces	403	423
Silver, ounces	451,627	439,007
Copper, pounds	248,771	288,819
Lead, pounds	5,016,627	5,273,216
Net smelter returns.....	\$642,467	\$500,498
Dividends	383,287	294,561

The Spiro adit is in over 5000 ft., the last 2300 ft. being

in Wideside shale, after which favorable ore-bearing formation is expected. Solon Spiro is general manager.

Dugway.—According to Israel Larson, superintendent for the Lucky Star Copper Mining Co., in the Deep Creek district, rich copper ore has been opened at a depth of 100 ft. This shoot has widened to 5 ft. and appears to be dipping toward the orebody on the 220-ft. level. Ore is being sorted preparatory to sending it to the smelter.

At a depth of 190 ft. in the Silver Bell mine, from 5 to 7 ft. of 7% copper ore has been opened. Some rich ore occurs in small pockets.

Marysvale.—Mineral Products Co.'s new mill is treating 200 tons of alunite daily, producing 20 tons of potash. This

Great Northern Mining Co., 15 miles from Keller, has done 1850 ft. of tunneling and opened a wide copper-gold vein.

Addison Copper & Milling Co., 7 miles east, has developed lead-silver ore.

Walla Walla Copper Mining Co. has sunk two shafts, is sinking another, and drove four adits a total of 1200 ft. Manager, J. E. Leonard, states that copper ore is to be shipped soon.

Manila Mining & Milling Co., four miles west, has been extensively developed, and is said to have a large quantity of ore in reserve.

Spokane.—While this city has for years been the recognized mining centre of the North-West, it is only recently that a mine has been developed within the limits of Spokane county. After a short period of development, high-grade native silver and galena ore has been opened by the Silver Bell Mining Co. near Loon Lake.

Walla Walla.—Niaga Placer Co. has been formed with capital of \$500,000, \$282,000 issued with shares at \$1 per. Trustees are M. Zuger of Waitsburg, A. M. Elam of Milton, W. B. Brooke, Ernest Knight, John Rosendahl, and Hugo Reinman, all of Walla Walla, and C. B. Brooke, of Seattle.

CANADA

British Columbia

Hedley.—Hedley Gold Mining Co. paid its quarterly dividend of 30c. per share on March 30. The sum was \$36,000, making \$2,339,520 to date. The last disbursement was a reduction of 20c. per share, 50c. having been paid for a considerable time.

Prince of Wales Island.—Complex mine of J. L. Harper, formerly of Republic, Washington, is supplying rich lead-zinc ore for a new 80-ton concentrating plant recently erected.

Ontario

Boston Creek.—O'Donald claims of 200 acres in this district are under 60-day examination for influential syndicate. Price, if results are satisfactory, is said to be \$250,000.

Cobalt.—Kerr Lake produced 204,153 oz. silver during February. This is equal to recent months, although February was three days short.

Pittsburg-Lorrain company is to experiment with a Groch flotation plant. About 10,000 tons of low-grade ore is available for treatment.

Trethewey Silver-Cobalt Mines Co. reports for 1917 that 34,722 tons of 13.3-oz. silver ore yielded an operating profit of \$114,935. Dividend No. 15 absorbed \$60,500. Silver in ore-reserves decreased from 361,482 to 264,944 oz. Several properties were examined with a view to purchase, and \$4819 was spent on one in Cane Township before stopping work. An option has since been taken on the Castle Mining Co.'s property.

Gowganda.—This district is short of fuel, it being almost impossible with deep snow to cut wood. Mining situation is reported to have never been better.

Kirkland Lake.—Elliott Kirkland company has opened from 18 to 24 in. of rich gold ore on 125-ft. level. This is considered an extension of Kirkland Lake company's vein.

Teck Hughes company in February treated 2374 tons of \$7.27 ore.

Tough-Oakes company has cut a new vein on 350-ft. level, assaying \$20 per ton across 6 feet.

Port Colborne.—International Nickel Co.'s new refinery will be finished within a few months. Capacity is 20,000,000 lb. of nickel per annum.

PART OF UTAH, SHOWING SITUATION OF MARYSVALE DISTRICT

replaces the plant burned in October last. An immense quantity of ore was blocked out during suspension of treatment.

Florence Mining Co.'s alunite mine adjoining will have a 100-ton plant operating by June. Jacob Young is in charge.

In the Iron Cap mine, 6 miles from Marysvale, a mixture of alunite and iron ore is being opened.

Copper, gold, and silver ores are being mined in the district.

WASHINGTON

Keller.—Lack of transportation facilities has hindered development and production from this region, but hopes are held that a railway may be built.

Iron Creek mine is the most developed property in the district. Ore contains copper and silver. A 25-ton mill is contemplated.

Illinois Copper & Mining Co., three miles west, has opened a wide vein carrying gold, copper, silver, and zinc.

Temagami.—Near Doherty siding silver ore has been discovered and a number of prospectors are busy. Between 1907 and 1910 a good deal of work was done in the district, revealing little of importance.

CHILE

Casapalca.—Backus & Johnston smelter in January produced 1,921,839 lb. copper. Average per month in 1917 was 2,025,697 pounds.

KOREA

Usan.—Oriental Consolidated Mining Co. reports for November that 200 stamps crushed 25,882 tons of ore. Extraction by amalgamation and cyanidation was \$139,410. Operations cost \$73,638, and improvements \$3010, leaving \$62,762 net.

January clean-up, as cabled, was valued at \$125,280.

MEXICO

Aguascalientes

Aguascalientes.—American Smelting & Refining Co. refuses to compromise with State authorities regarding the tax levied. This amounts to \$9000 per month, which the State offered to reduce to \$1500.

Mexico

Mexico City.—A decree issued March 23 prohibits exportation of gold in bars and of Mexican and foreign gold coins. It provides for the exportation of gold and silver bullion by special permit in each case. As to the exportation of ore and concentrate containing gold and silver, the decree issued in September is still in effect. Silver pesos may be exported, by special permit in each case, if gold to the same value is imported in return. The decree exempts gold in bars and National and foreign gold coins from consular fees and does not require consular invoices.

A U. S. Consular Report states that the Mexican government has issued a decree fixing taxes as follows on petroleum lands. First, on petroleum lands being developed by lessees under contracts made prior to May 1, 1916, 10% of the annual rental up to \$5 per hectare, 20% of the annual rental from \$5 to \$10 per hectare, 50% of the annual rental above \$10 per hectare, and 5% of all royalties paid by the lessee to the lessor; second, on oil lands being developed by the owners of the land \$5 per hectare annually, and 5% of the products annually; third, oil lands for which no rental is being paid are taxed \$5 per hectare annually, and oil lands on which no royalties are being paid are taxed 5% of the products annually.

Since 1913, according to figures issued by the Department of Commerce, Industry and Labor, gold and silver valued at \$125,000,000 have been extracted in Mexico. In the same period copper production was \$31,000,000, and lead \$5,000,000.

Utah section of A. I. M. E. entertained, on April 4 at Salt Lake City, the Institute president, Sidney Jennings; first vice-president, Charles W. Goodale; and secretary, Bradley Stoughton. V. S. Rood and J. A. Norden read a paper entitled, 'Engineering problems encountered during the recent mine fire at the Utah Apex mine at Bingham, Utah.' On April 8 the Columbia section of the A. I. M. E. entertained the above officials at Spokane, Washington. During the period of June 16 to 20 the San Francisco section will also entertain them. No definite date has yet been fixed.

The Australian Institute of Mining Engineers on January 21 elected J. W. Sutherland of the Golden Horse-Shoe mine, at Kalgoorlie, Western Australia, president for coming year. The annual report states that 117 members are on active service, several of whom have been decorated for conspicuous bravery.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Henri Jequier is here from Penarroya, Spain.

J. B. Tyrell was at Tulsa, Oklahoma, last week.

Samuel H. Dolbear has returned from Washington.

F. L. Sizer, after a visit to Merced, has gone to Arizona.

D. M. Riordan is expected in San Francisco from New York.

Clyde E. Tilford, of Ely, Nevada, has joined the 27th Engineers.

George H. Garvey is on geological examination work at Tonopah, Nevada.

R. S. Baverstock, of Baverstock & Payne, Los Angeles, was here this week.

F. A. Fahrenwald of Cleveland, Ohio, is expected shortly in California on his way from Arizona.

S. A. Ionides enlisted in a Canadian regiment and is now in the Explosives Department at Ottawa.

D. D. Homer, recently superintendent of the Jerome Del Monte mine, at Jerome, is in San Francisco.

H. L. Christensen has resigned as mill superintendent for the Alaska Juneau. He is now in San Francisco.

Hanzo Murakami, geologist of the South Manchurian Railway, is in Utah studying American mining methods.

Bulkeley Wells, Robert E. Cranston, Roy H. Elliott, and Wilbur H. Grant are now at 313 Hobart Bldg., San Francisco.

Frank Crawford, superintendent for the Doctor-Jack Pot Mining Co., has been appointed superintendent for El Paso Consolidated Gold Mining Co., at Cripple Creek. He succeeds Owen Johnson, who resigned.

Allen H. Babcock has been appointed Western representative of the Naval Consultation Board. Inventions likely to be useful for the War should be submitted to him at his office in the Southern Pacific building, San Francisco.

A. F. Brigham, late general manager of the Jaegersfontein diamond mines, South Africa, has been appointed general manager for the Hollinger Consolidated at Porcupine, Ontario. P. A. Robbins, formerly general manager, will be managing director.

The California State Civil Service Commission announces two examinations for senior and junior geological draftsmen, to be held at Sacramento, San Francisco, and Los Angeles during the year 1918, on April 20 and October 19. The salary ranges from \$100 to \$150 per month for the senior, and \$75 to \$100 for the junior draftsman. Duties of the senior include the compilation and drawing of topographical, geographical, and geological maps, and geological cross-sections from field notes and other data. Duties of the junior include map tracing, compilation of geological data, and the drawing of cross-sections from field notes. Candidates as senior draftsman must be graduates of recognized engineering colleges, or must have had at least three years varied experience as a draftsman, and a common school education. Candidates as junior draftsman must have had at least two years of work in an engineering college of recognized standing, or at least two years varied experience as a draftsman, and a common school education. A knowledge of geology and mineralogy is desirable in both positions. Persons desiring to enter either of these examinations may secure application blanks from the Commission at the Forum Bldg., Sacramento; Ferry Bldg., San Francisco; and Hall of Records, Los Angeles.

San Francisco, April 2

Antimony, 45% metal, per unit.....	\$110
Chrome, 38% and over, f.o.b. Cal., per unit.....	\$1.25-2.00
Magnetite, crude, per ton.....	\$8.00-10.00
Magnetite, 40%, f.o.b. New York, per unit.....	\$1.20
Magnetite, 40%, at Honoluli, Cal., cents per unit.....	75
Manganese, chemical, per ton.....	\$80-100
Tungsten, 60% WO ₃ , per unit.....	\$24
Molybdenite, per lb., 85% MoS ₂ (nominal).....	\$1.80
Pyrites, domestic, per unit of sulphur, cents.....	28

Chrome prices are to be fixed at an early date, probably between the above-mentioned figures.

EASTERN METAL MARKET

(By wire from New York)

April 2.—Copper is quiet. Lead is dull and easier. Spelter is inactive and lower. No quotations for platinum.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

A big factor in the recent rise in silver is through China's import season just coming to an end, and its exports are beginning to assume customary large business. These Chinese exports are paid for in bar silver. Hence a large increase in that country's demand is expected. Another factor which accounts for the silver scarcity is low stocks at smelters. The severe winter not only hampered smelter output, but transportation was seriously impeded. This caused smelters to use up stocks on hand, and the winter restrictions are just beginning to have an important effect on the silver market.

Dividends paid by copper companies during first quarter of 1918 totaled \$36,717,447, against \$45,362,926 in 1917, and \$29,537,100 in 1916.

Refining charges of the Nichols Copper Co. at Laurel Hill, New York, have not been increased 33%, as stated here on March 23, but it is probable that this and other refiners will ask the Government to include in the new price for copper to be fixed after June 1, an additional charge, say 1/4c. per lb., so that refineries can operate at maximum production in these abnormal times.

Eastern Metal Market

New York, March 27.

All the markets are quiet, in some cases lower, and in no case have they advanced.

Copper is featureless and is closely controlled.

Tin has been active again for futures, with spot metal nominal and unobtainable.

Lead is quiet and easier.

Zinc is not active, but is considerably weaker.

Antimony is nominally a little lower.

Revised prices of the iron and steel schedule were announced yesterday at Washington. The revision is not extensive. It is to hold for three months more from April 1, though earnest efforts were made to lengthen the period. Actually, few changes were made. Basic pig-iron was advanced \$1 per ton, bringing it to \$32, and bessemer iron, \$1.10 per ton, that is, \$35.20, foundry iron being left unchanged. The only other change made in the entire schedule was a reduction of \$1 per ton in heavy melting-steel scrap. The arrangement is satisfactory to the large steel-makers, excepting the question of its duration. Such producers expressed a willingness to sell ingots and slabs to the smaller plate producers at special prices so that the latter might continue to roll plates at a fair profit. These desired higher prices on plates.

"The effort of the Shipping Board to get ships from the manganese-ore trade with Brazil is a matter of concern to the entire steel industry," says 'The Iron Age.' "The development of domestic manganese supplies proceeds slowly, but considerable increase is promised for the second half of the year. Meanwhile an increased use of spiegeleisen will be of some help."

COPPER

There have been no new developments in the past week, and the situation appears to be satisfactory. Inquiries as to supplies elicit the information that there is at present enough to go around and that, while the output is not at the maximum capacity, it is expected to reach 200,000,000 lb. per month in the near future. This output will be necessary to fill all international demands, which are the greatest ever recorded. Railroad congestion, or incapacity, still exerts its influence on the copper market, but not as strongly as heretofore. Some consumers not having Government work still meet difficulty in securing supplies, and are also in the market for early and in some cases for prompt delivery, but the tendency is not to meet these wants fully, in order to conserve supplies. All trading is regulated by the Government price of 23.50c. for carload and larger lots, and 24.67½c. for less.

TIN

Last Wednesday, March 20, there were good sales of future metal at 76c. per lb. and upward; more could have been sold had there been sellers. This was also true of Thursday and Friday when considerable inquiry was noted. The feature of the situation is that sellers are really scarce; hence that it is difficult for buyers to cover. A serious phase of the situation is that many foreign houses actually have grown weary of doing business here. Trade comment is to the effect that no blame justly can be attached to them, because the conditions in this country are positively 'rotten'—as some express it. These dealers are now subject to all manner of Government regulations, red tape, and other difficulties, so that they are losing large sums in interest and through other charges. On Monday, March 25, a fair business was done, but the market is now quiet. Arrivals to

March 25, inclusive, were 1472 tons, with 6300 tons reported afloat. The London market has fallen as compared with that of a week ago. Yesterday, spot Straits was sold at £317 10s., or £4 under sales made a week ago.

LEAD

It is stated that odd lots have been offered in the last week at 7c., St. Louis, or 7.17½c., New York, but it is probable that these were special offers to special buyers, and that they do not represent the market. They are indicative, however, of the fact that the tone is quite a little easier. Quotations are fundamentally unchanged at 7.25c., New York, for both the A. S. & R. Co. and the outside market, with the St. Louis price at 7.10c. Railroad congestion has improved enough to relieve the market here of its paucity of supplies. This, together with the fact that buyers are not as numerous, explains the easier conditions. The spot market is quoted at about 7.37½c., New York, which is a little lower than last week. Jobbing lots of five tons and less, which a short time ago brought 7.75c., were not accepted when offered this week at 7.50c., New York.

ZINC

The market has grown weaker than was thought possible some weeks ago. Prime Western for April delivery, even for May and June, has been offered and sold as low as 7.25c., St. Louis, or 7.50c., New York. One large dealer quotes as low as 7.12½c., St. Louis, today. Undoubtedly the market is lower than a week or two ago, but just what the time-level may be is hard to define. It is believed that sales have been made—small ones likely—by means of quietly negotiated transactions. It is also market opinion that some dealers have been or are pressing their product on the market, and that this is the cause of the present weakness. Without question the metal is cheap at the above prices, and if any demand exists it should come out now. Some dealers are unwilling to meet these prices, contending that sales at those levels represent an actual loss. Grade A is officially held at 15c. per lb. and is in strong demand for Government uses. Sheet-zinc is pegged by the Government at the 12c. per lb. basis.

ANTIMONY

The market is nominally lower at 13 to 13.25c. per lb., New York, duty paid, for Chinese and Japanese grades. Demand is very light. Imports of matte, regulus, and metal in 1917 were 35,649,113 lb. against 19,749,830 lb. in 1916, and 17,484,030 lb. in 1915.

ALUMINUM

There has been no development since a week ago. Official prices on scrap have not been announced. On No. 1 virgin metal, 98 to 99% pure, the Government price of 32c. per lb. for 50-ton and larger lots rules; while for 15 to 50-ton lots, 32.10c. is the price, with 1 to 14-ton lots pegged at 32.20 cents.

ORES

Antimony: The quotation is about \$1.75 per unit, but only a light business is reported.

Tungsten: The market has been active and scheelite has sold at \$24 to \$24.50 per unit of 60% concentrate. Wolframite sold at \$24. One dealer reports that off-grade ore has declined \$1 per unit. Ferro-tungsten is quiet at \$2.25 to \$2.40 per lb. of contained tungsten. For domestic consumption \$2.40 is asked, while the lower quotations apply to foreign inquiries.

EDITORIAL

IN the article on 'Testing an Air-Compressor,' by Mr. Walter S. Weeks, in our last issue, there was a typographical error in the tabulated statement on page 482, where the cubic feet of air corresponding to a water-column of 12 inches should have been 74.36, and for 13 inches, 77.44. The error would be detected by a careful reader, and by comparing the figures with the chart of nozzle-discharge; however, we mention it in justice to the author.

THE silver bill drafted by Mr. Key Pittman, Senator from Nevada, has been approved by the Treasury Department. The quantity of coin that would be melted under this bill, if it should become law, has been increased to \$250,000,000. The measure is now before Congress. This plan for releasing silver for export, and gradually replacing it by renewed purchases of bullion in the market, was discussed editorially in our issue of February 16. Its effect would be to expand credits against a metallic basis, at the same time offering relief and incentive to the silver miners at a time when a market at prices fixed by the Government will be particularly useful to them, and will enable the producers to contribute to the financial strength of the country, as they have done at other periods of national stress.

RECENT reports from the great Bawdwin mine of the Burma Corporation show an increasing proportion of copper in the ore, which hitherto has been mainly valuable for silver, lead, and zinc. On the fifth and sixth levels high assays of copper have been recorded, in one case the copper content for 854 feet ranging between 7 and 21%. This is interesting, for it may presage the uncovering of a large tonnage of copper ore. American experience has shown that silver and lead near the surface are succeeded in depth by copper often enough to justify the expectation of such an order of deposition. The average miner and prospector can be restrained with difficulty from arguing that the relation has been proved to be a necessary sequence. The mines at Butte were originally worked for silver, and the appearance of copper brought discouragement at first; lead and zinc are found in association with these deposits, and the magnitude of the zinc output of the Butte & Superior, Elm Orlu, and other mines bids fair to rival the copper pro-

duction of the district. At Bisbee lead, as well as copper, was found at the surface in the early years of development, and it is still a factor in the metallic output, whereas zinc is found in many places, particularly associated with the deep pyritic ores of the Calumet & Arizona. The Yankee Girl, in Colorado, was started as a silver-lead mine, although it achieved fame as a source of copper ore, containing the precious metals. Other examples will come to the mind of the reader.

IN our issue of March 16 we published two letters protesting against the imputation, made by our correspondent in Mexico, that the Compañía de Minerales y Metales was German-controlled and we were informed that 97.7% of the stock was held by the American Metal Company. On April 4 an Associated Press dispatch announced that two directors of the company last mentioned had "been given permission to open negotiations in Switzerland with German holders of 40% of the stock of the company." If 40% of the parent company is German and if it owns 97.7% of the subsidiary, then at least 39% of the subsidiary is German controlled; this does not include the holdings of naturalized Germans; in short, the German share-holding is large enough to warrant the phrase "German-owned," to which strong exception was taken by an engineer for whom we have sufficient regard and respect to regret a decided difference of opinion.

AMONG the feats of engineering contributing to the successful waging of the War we like to record the manner in which the interned German ships were made ready for use after they had been damaged. The Germans did such damage as would, they estimated, put the vessels out of service for two years. The 37 German ships, of 700,000 total tonnage, had their 74 engine cylinders so broken that speedy repairs seemed impracticable. Some of the castings required for the biggest vessels were supposed to be beyond the capacity of any American foundry. The Shipping Board estimated the bill for repairs at \$2,600,000, and the time required at 18 to 24 months, yet the job was accomplished in 7 months at an expense of only \$273,000. One of the first ships tackled had four broken cylinders and it was estimated that 18 months' work would be required, but

within 60 days the engines were repaired, and within 90 days the vessel was ready for sea; indeed the time taken for repairs in many instances was hardly more than that needed for such overhauling of the machinery and cleaning of the bottoms as was necessary after so long a period of inactivity. Many of these ships are now stronger than before, and they are being operated more cheaply than by the Germans. The most striking example is the 'Vaterland', which is 907 feet long, or 200 feet more than the height of the Woolworth building in New York, and is rated at 54,282 gross tons or 23,548 tons net. She has 18 decks and 18 elevators. Cylinder castings weighing 70 tons each were required and there was no dry dock big enough to hold her except at the Panama canal. The thirteen breaks in the cylinders were patched by electric welding, without a single rivet having to be put through the $3\frac{1}{2}$ inches of metal. Many improvements were made and within a few months after seizure the great ship went forth at a 21-knot speed using 200 tons per day less coal than before. She is now called the 'Leviathan', and is credited with transporting 15,000 soldiers in a single voyage across the Atlantic, making her last round trip in 11 consecutive days. The Germans were misled—they were badly fooled—by their conceit. American invention and enterprise used constructively was more than a match for their sabotage and meanness used destructively.

WATER-POWER development at length has emerged from the realm of academic discussion into that of practical consideration by the leaders of industry. A year after assuming belligerent responsibilities in a contest that jeopardizes the future welfare of the Republic, the stupidity of our restrictive national policy toward the utilization of water-power has been realized. Congress now has the question before it in the form of a bill, on which early action is expected. The Chamber of Commerce of the United States, representing half a million of the progressive men of the country, has registered its conviction that proper enabling legislation is urgently required. It is pointed out that the available undeveloped water-power of America exceeds the total steam-power at present in service. Most of the water-power is controlled by the Federal government. The advantage of hydro-electric power, from a financial standpoint, is not as pre-eminent as the public has imagined, because it requires a very large initial investment, and it is not so readily increased as steam when necessary to meet a growing demand. The conditions under which it may be controlled must be freed from onerous burdens in order to make it attractive to capital. This has not been done in the past. It must be noted also that efficiency in steam-engineering has become so great as to admit of generating power with coal in competition with water-power at many Eastern points. On the other hand, the saving in the conservation of fuel and labor, and the release of an enormous carrying capacity of the railroads to more urgent uses, is of such vital moment in the present crisis that strenuous efforts are needed to

permit the harnessing of water-power with the utmost speed. The merits of the bill before Congress may be open to discussion, but the debate must be decisive and practical, and, above all, of a constructive sort, leading to a wise decision without waste of precious time. It is the duty of every citizen to urge upon Congress that this measure be dealt with promptly, and in a broad spirit commensurate with the tremendous National issue at stake.

SUFFICIENT attention has not been paid to the fact that Germany is playing a clever game in her economic dealings with the Ukraine and Rumania. The German papers characterize the treaty with the Ukraine as a 'bread peace,' and that with Rumania as an 'oil peace.' This accentuates the special needs of Germany, but, on the other hand, she is not oblivious to the necessities of the peoples who have been forced to make terms with her. Certain German factories have been assigned to the production of goods urgently required in the conquered districts, and careful attention has been given to stabilizing exchange, so as to facilitate commercial intercourse. This tends to repair the ravages of war, and to ease the conditions of living, thereby promoting a revival of friendly feeling. Another device for re-establishing confidence is that of making part-payment for Russian goods in Russian securities, thus encouraging the development of industrial operations and the rehabilitation of the railways, by definitely placing the control in the hands of domestic capitalists. In the face of this it will be seen that German commercial penetration is being accomplished by methods that tend to allay animosities and to give the Central Empires a strength in the East that will increase their power of resistance. It also lessens our right to expect political opposition in Russia in aid of our cause. To count upon any effective uprising there is to base our campaigns upon false hypotheses. Germany is now using economic weapons where we cannot reply in kind. It makes more imperative the need of developing our military offensive to the highest degree of efficiency and strength, for it is by arms alone that we can win.

Oil-Shale in Colorado

We publish another article on this subject, this time by our regular correspondent at Denver, Mr. Arthur J. Hoskin, a mining engineer particularly well informed concerning the mining industry of Colorado. The article is sufficiently comprehensive to give an excellent general idea of the conditions governing this new departure in mineral exploitation. The region now the scene of this activity is one well known to fishermen and to hunters of big game; it is one of the most attractive portions of Colorado. Fortunately the shale deposits have been examined and described by the U. S. Geological Survey, and if public interest in the subject is sustained it may be assumed that the Director of the Survey will arrange for the publication of further information. Although a

comparatively undeveloped industry in this country, the exploitation of oil-shale is a relatively old industry in Scotland, where in 1913 an output of 3,280,000 tons of shale yielded 1,718,000 barrels of crude oil, the average yield being about half a barrel, or 20 gallons, per ton. In Colorado, it is estimated, there is sufficient shale of even greater oil-content to yield 20 billion gallons of crude oil, from which two billion gallons of gasoline may be extracted. These figures suggest the possibilities of one region only, for in Utah and Indiana, for example, other resources of the same kind, and of equal magnitude, are available for judicious enterprise. Mr. Hoskin describes the character of the rock formation, and outlines the methods of mining, development, and distillation. He lays stress on the tentative nature of most of the work now in progress, but writes hopefully concerning the outcome, the ultimate success of which must depend upon adapting Scottish and Australian practice to local conditions. He places particular emphasis upon the need of good engineering advice, pointing to the fact that in such a new field of enterprise it is likely that expert advice will be set aside too readily by the promoters of speculative schemes. The operations require the use of mining, mechanical, and chemical experience such as is readily available, at Denver, for example; therefore the public is advised to insist upon proper guidance in all technical matters, for without it much money will be squandered.

American Smelting v. Bunker Hill

We are informed that the controversy, developing into serious litigation, that has existed for several years between the American Smelting & Refining Company and the Bunker Hill & Sullivan Mining & Concentrating Company has been settled out of court. In our issue of December 1, 1917, and on other occasions, we have referred to the dispute over an ore-contract culminating in a suit commenced by the Smelting company in the Federal Court of Oregon, followed by a petition for a temporary injunction against the continued operation of its own smelter by the Bunker Hill company. When preparations were under way for the trial of the suit it was realized, we are informed, that the contract was so indefinite in many particulars as to afford ground for persistent litigation. Therefore the parties in controversy, by mutual agreement, have cancelled all contracts between them and entered into a new one whereby the Smelting company receives a portion of the ore of the Bunker Hill company at rates that are satisfactory to both parties. In previous references to the subject we have mentioned the salient facts. The principal contract was for a period of 25 years, from 1905, but it provided fixed terms for only the first five years, covering such of the output as contained between 30% and 75% lead. It did not require the Bunker Hill to put its ores through a mill, and, as the ore from the mine averaged less than 5% in lead, it was possible to contend that none of the

ore came within the limits specified. As a matter of practice, however, the Bunker Hill company did concentrate most of its ore and its methods of concentration were such that at times nearly a third of its output was a product containing more than 75% lead. As this grade of material did not fall within the binding terms of the contract, it was provided that the Smelting company should have an option to purchase this product by giving the Bunker Hill "the best going market rates and terms." When the latter company built its own smelter, last year, it placed itself in a position, by bidding for other ores produced in the Coeur d'Alene, to make the terms that it should receive for its high-grade product, in the event that the Smelting company should exercise the option. Another interesting dilemma arose over the concentrate of intermediate grade, between 30 and 75%. The contract, as amended, fixed definite terms for the ten years between 1905 and 1915; after that and for the remaining 15 years the Bunker Hill was to receive at least the terms obtaining during the first period and any better terms that might be granted by the Smelting company to a majority of independent 'shippers' in the Coeur d'Alene, so long as the Smelting company should continue to purchase a "majority" of the Coeur d'Alene ore; but if this company should cease to do so, then it was obliged to give the Bunker Hill not merely the terms that had been in force, but was obliged to meet the terms of its competitors in the smelting business. The Smelting company did receive the major portion of the Coeur d'Alene output during 1915, 1916, and 1917 on terms that were no better than those which the Bunker Hill received during 1905 to 1915, therefore the Smelting company, by omitting to make new contracts, was in a position to continue the old terms, assuming the contract to be binding, so long as it refrained from making a market and so long as it retained control of the regional production of lead ore; but it was apparent that a time would come when such inaction would entail the loss of the major production from the Coeur d'Alene and therefore the loss of the Bunker Hill output, or the Smelting company would be compelled to meet its competitors' terms, which necessarily would be affected by the new competition of the Bunker Hill smelter. Meanwhile two of the mines that had been shipping to the Smelting company became exhausted, so that since the beginning of the current year it has not been receiving the "majority of the ores" [a phrase suggesting the poor wording of the contract]. Moreover, the Bunker Hill smelter was receiving so much outside ore that it was not dependent on the output of its own mine, and would have been embarrassed if it had to treat that output in addition to the current receipts of custom ore. The contract was uncertain in its definition of the means for ascertaining the rates accorded by competing smelters, and as these terms might be changed with each new contract made in the region, it seemed likely that the controversy would persist until the expiration of the contract. For these and other reasons both parties concluded to cancel the contract and enter into a new one that promised to obviate litigation.

Undoubtedly they have been wise in so doing, but we regret the event nevertheless, because we have reason to believe that it would have been to the public interest to have a suit in the course of which the methods of smelting companies would have been bared, particularly in so far as they involve preferential rates from the railroads and combinations against the producers of ore. We rejoice, however, that a possible menace to the success of the Bunker Hill smelter has been removed and that this independent plant will continue to exercise a healthy influence in the ore-purchasing business of the North-West.

Prussian or Bolshevik

The Russian debacle, following the impact of the Prussian idea on the revolution that we hailed a year ago as the latest flower of democratic aspiration, presents a sinister picture to the student of social philosophy. On the one hand we see the concrete expression of highly organized and frankly autocratic militarism and on the other the disintegration of a nation plunging into the chaos of sentimental anarchy. To which of these extremes is the world drifting? Apparently it is one or the other if we and our Allies do not win this war soon. Are human beings willing to surrender their conscience to the idea of a State that, like the king of an outworn dogma, can do no wrong, and therefore may commit crime without shame, or are they to assert their individualism to the extreme of destroying all social order? That seems to be the choice of evils offered to civilization today by the pacifist and non-resister. The prostitution of patriotism to a highly effective form of international brigandage has been so fully exemplified by Germany that we are left in no doubt as to the ends and purposes of kultur, the idea of the beast that has the brains of an engineer. We loathe the idea and its many bestial manifestations; we question even the efficiency of its sponsors; to us the claim of superlative sagacity and supreme competence is incompatible with the insanity of plunging into such a war a people that by peaceful penetration was in process of acquiring all the commercial advantages and political influence that it wanted. Has the German proved himself fit for world dominion? The question is derisive. He does not play the game; he has fought bravely, but with a dirty meanness that has provoked contempt; he has no psychical intuition, his diplomacy has been that of the spy; he has proved himself less chivalrous than a pirate and less humane than an Apache. To a Napoleon, a Caesar, or an Alexander the world might, if compelled, yield service, but to the pitiful paranoiac at Berlin it refuses even the respect given to unscrupulous tyranny. To us the Prussian idea, which is now German, is the negation of all that for which we have striven since the United States came into being—nay, since Magna Charta was signed. It stifles the aspirations of every democracy, of every attempt at democratic government since man emerged from the jungle. It is a return to the brutishness of the ape and the tiger.

We repudiate it with all our heart and soul; we shall fight it as long as we have an arm to raise in forceful protest. But what of the alternative that begins to glibber at us from amid the reek of war? Is Bolshevism any better? Let the Russian reply. The bureaucratic regime of the Romanoff did at least ensure some kind of social order, some maintenance of industrial activity, some assurance of food and clothes; now these elementary requisites to human welfare are gone, and with them all that stood for any sort of stability, that is, the rights and responsibilities recognized between members of an organized community. With cynical effrontery the propaganda of the German autocrat has urged the Russian to assert himself to the point of discarding military discipline, repudiating financial obligations, confiscating all forms of property, and labeling every intelligent citizen a 'bourgeois' and therefore anathema. The Bolsheviks have served the German purpose only too thoroughly, demoralizing as well as demobilizing the armies that fought so heroically for two years, opening the gate to the invader, and wantonly discarding the intelligence of the country at the moment when it was most needed to guide her destiny. This destruction of the complex machinery of a nation's life is the pestilent growth not of socialism but of anti-social perversion of the true socialistic spirit; it is the expression of unrestrained individualism, for which 'internationalism' is a mere cloak. This political catch-as-catch-can, this anti-social wrestling with all the forms of established order, is a reversion to the jungle; it leads nowhere except to social chaos, that is, anarchy or nihilism. To the liberal, longing for the fulfillment of the American idea—equality of opportunity—it is a bestial satire, no more and no less. It is a curious manifestation of human unreason and it is portentous, for, if the War last long enough, we see the danger of an infection from this intellectual meningitis. The blasts of war may blow the poison-gas across the world. The carnage and destruction of battle cannot continue forever; sooner or later even a disgraceful peace will seem preferable to the weak-minded and feeble-hearted, of whom every nation has a share. It would be in accord with the justice of things if the German propaganda, like their chlorine, were blown back from Russia into their own ranks. It is likely, if a military decision does not anticipate the event. The wish may be father to the thought, and the same wish leads us to hope that the I. W. W. and similar Bolshevik tendencies may be abated both in the United States and in Great Britain. Unless we check Prussianism we shall be endangered by a growth of the non-national, anti-social, purely individualistic and essentially uncivilized spirit of Bolshevism, which, like Prussianism, is the negation of that orderly co-operative and social trend of human affairs for which intelligent men generally—outside Germany—are striving. Our destiny depends upon the winning of this contest against two enemies of representative government—that kind of government on which we stake our existence as a nation—those two enemies being tyranny and anarchy.

Cascade Method of Froth-Flotation

By H. HARDY SMITH

Modern flotation practice is almost entirely concerned with what is now known as air-froth flotation, and the practice of air-froth flotation is in turn largely concerned with methods of getting atmospheric air into intimate association with a mixture of mineral particles in water. The process therefore can be subdivided according to the manner in which the air is introduced, and at present there are three distinct processes, first, the mechanical agitation or Minerals Separation process,

Fig. 1

second, the pneumatic or Callow process, and, third, the fluid-jet air-entraining or Cascade process. The last is of recent origin and at present is in use only to a limited extent in comparison with the other two processes. Owing to its intrinsic merit, however, it bids fair to occupy an important position in the metallurgical use of froth.

The Cascade process works by virtue of the fact that a stream or jet of fluid tends to drive or carry contiguous particles of a surrounding fluid along with it, as a result of the friction at the interface caused by the adhesion between the two fluids. This principle was recognized centuries ago, and was applied by means of the 'trompa' or hydraulic air-compressor, to supply air at low pressures for the Catalonian forges. About the middle of the last century it was employed in the form of the jet-pump and the jet-ejector, and it also enters into the action of the modern steam-injector.

The extraordinarily large volume of air or gas that can be injected by a jet of water against a moderate resistance by this means, leads to the supposition that the force of adhesion between air and water is greater than had been commonly supposed. The operation of the hydraulic air-compressor depends primarily on the grip that a rapidly descending surface of water can obtain on the contiguous air, and the high efficiency, which many of these contrivances have shown, is evidence that the forces engaged are not fickle or elusive, but are constant and reliable.

In the Cascade flotation process, the jet or stream of

Fig. 2

fluid is not only employed to introduce air into the body of the pulp, but its kinetic energy is absorbed also in producing agitation, so as to thoroughly disseminate the bubbles throughout the mass and to assist them in their grasp upon the mineral particles which are to be floated. This agitation is not to be compared in its intensity to that in the method of mechanical agitation, but is more in line with that produced by the pneumatic process.

It is important to distinguish between the kinds of bubbles. In a froth-flotation sense there are active and inactive bubbles. Air introduced into the body of a liquid necessarily must produce bubbles before it escapes at the surface, since a bubble is merely a certain volume of air surrounded by a liquid, but, from a flotation standpoint, some air will be consumed in forming useful bubbles, and the remainder will escape without performing any useful purpose. For example, a jet of air blown into a pulp free from a frothing contaminant, even if the other flotation conditions are good, will produce mostly inactive bubbles, and, even if a frothing agent be present,

the proportion by volume of inactive bubbles will be large. Apparently the activity of a bubble is in inverse proportion to its diameter, but there may be other less obvious factors.

In the so-called pneumatic process of froth-flotation, the enormous production of bubbles for a given result is its most striking characteristic, a point which would lead one to suppose that the proportion of inactive to active bubbles is large, and consequently that the 'bubble-efficiency' is low. On the other hand, the froth production for a given result with the Cascade method is decidedly moderate, and consequently the bubble-efficiency must be relatively high. In this respect it probably does not equal the method of mechanical agitation, but the large consumption of energy to produce the bubble and transport it through the pulp to the surface, in the latter method, is an economic drawback. It will be necessary to learn more about the fundamental physical principles governing the production of bubbles in liquids before it becomes possible to indicate the reason for this high bubble-efficiency inherent in a volume of air injected as a film adhering to a fluid surface in rapid motion; but whatever be the reason, the fact remains that this method of introducing air and of agitating brings about the desired results in a particularly pleasing and efficient manner. The Cascade process is the logical outcome of the growing recognition of the importance of air in froth-flotation practice, since anyone of ordinary intelligence could not stand below a waterfall or a cascade, and observe the intense aeration in the pool beneath, without immediately being struck by the potentialities inherent in this method of agitation, were he cognizant of the fact that in this intense aeration lies the basic principle governing the successful froth-flotation of minerals.

On the economical and practical sides the strong points in favor of the Cascade process are: the simple and inexpensive plant, insignificant wear and tear, low repair-costs, small power-consumption, and the meagre attendance and regulation required to keep the plant running under good conditions. The honor and credit for first recognizing the principles underlying the Cascade process, and for embodying them in practical form, seems to be due to Messrs. Seale and Shellshear, of the Junction North mine at Broken Hill, Australia, where a full sized working plant was put into operation about the end of 1914. As frequently happens, the same idea was hit upon and developed independently at practically the same time in other widely separated localities, namely, at the Arizona Copper Co. in the United States and at the Suan mine in Korea. Later on, in 1916, U. S. Patent No. 1,187,772 was taken out by G. E. Ohrn, and another, No. 1,202,512, by Gustaf Gröndal, both of Sweden, for apparatus embodying the Cascade principle. About the same time a simple machine of true Cascade type was evolved at the Mineral Farm mill, at Ouray, Colorado. Recently Commonwealth Patent No. 2353 16 was taken out by L. V. Waterhouse, of Mt. Lyell, Tasmania, for a novel form of the Ohrn machine. Although all the contrivances developed by the various

investigators contains the same fundamental principles, the method of application differs widely. With some of the plants it is claimed that violent preliminary agitation and mixing of the flotation reagents with the pulp is unnecessary, but in most cases it will be found that this is highly desirable. The excellent mixing and emulsification which can be obtained by grinding the ore with the reagent in a tube-mill, in certain cases, may be sufficient, but supplementary agitation of the pulp, diluted to a consistence suitable for flotation, will not, in the general run of cases, be found amiss. In the apparatus developed at the Junction North mine, followed by other mines at Broken Hill, and by the Arizona Copper Co., as well as at Suan, and at Mineral Farm, the force of gravity alone is relied upon to inject the air and to disseminate it through the pulp. If insufficient natural fall is available, artificial fall must be created by means of elevators or pumps, which, at the same time, can be relied upon to provide a certain amount of the desirable preliminary mechanical agitation. In the Ohrn and Gröndal forms, the energy of high-pressure steam is employed, and in the Waterhouse machine, that of high-pressure water or solution. In these latter types it is safe to assume that preliminary violent agitation is not so vital, since the energy expended within the machine itself is greater than in the simple gravity-types.

The necessity for providing equalizing apparatus at the head of the plant is even more important in the case of the Cascade process than in other flotation processes, especially with gravity plants, since the nature of their operation makes them very sensitive to fluctuations in the volume of the feed. This lack of flexibility is one of the chief disadvantages of the process. A plant once designed for a certain tonnage, or more correctly, for a certain volume of pulp per unit of time, will not work satisfactorily at points much above or below this volume, and adjustments to suit altered conditions are not readily made.

In certain cases the froth produced in the Cascade process is extremely evanescent, and if allowed to occupy areas approaching those used with other flotation processes, the result will be failure. Where disappointing results have been obtained in trials with the process, it is fairly safe to assume that this was one of the points not fully comprehended. The ratio of frothing area to capacity is one of the most important considerations in the design of a plant. On account of the frail froth that is liable to be encountered, another important thing is to provide for short travel and rapid removal of the froth-concentrate. A Cascade machine, in the design of which proper attention has been paid to the above two points, will be found particularly efficient on coarse material, or in preferential flotation. In the case of a relatively high-grade pulp, containing a large proportion of readily floatable sulphide slime, the points mentioned may not be of such importance.

Turning to the mechanical details, Fig. 1 is a diagrammatic sketch of the simplest type of apparatus, and the only one which is accurately described by the name

'cascade'. Its chief recommendation is its simplicity. The feed-apron spreads the moving liquid into a sheet, and although this gives a large area, it is not the maximum area in contact with air that the same volume of liquid could provide. This would lead to the supposition that the efficiency of the machine is not high. In the one

Fig. 3

Fig. 4

developed at the Mineral Farm mill, not even crowding-boards were employed, the apron simply discharging into a box of square section, and the float being skimmed off continuously by a paddle. The results are said to be quite satisfactory. The capacity of a plant depends on the length of the frothing-boxes and the intensity and time of treatment on the number of steps or cascades. Both can be increased indefinitely, but it is preferable to have not more than six steps in succession, and, if further treatment is necessary, to interpose an elevating device to raise the pulp to the next tier. The frothing-boxes

Fig. 5

must be properly designed to suit the hydraulic head of each step, otherwise a loss of energy will result. This applies to all types of gravity machines. With the type shown in Fig. 1, a 30 to 40-in. head will usually be sufficient.

A more advanced type of apparatus is represented in Fig. 2. In most cases this could be expected to yield better results than the arrangement shown in Fig. 1, yet it is open to the objection that it involves more mechanical complication, and there is a loss of head between the steps, in consequence of which the total fall may not be utilized to the greatest advantage in the aerators. The capacity of the plant depends upon the dimensions of the induction-pipe and the frothing-pot. These cannot be increased indefinitely, so that a multiplication of units is necessary for a large tonnage. Very large volumes of air can be entrained by means of the induction-pipe, either with or without the small air-pipes shown in the aerator in Fig. 2, and this part of the apparatus is undoubtedly efficient both as an aerator and as an agitator, in combination with its bucket or diaphragm. A length of induction-pipe of 25 to 30 inches in the clear will usually give good results, but to get the total height between steps, the loss of head in the aerator (6 to 8 in.)

and in the under-flow pipe from the preceding frothing-pot must be added to it. The latter will depend on the density and coarseness of the pulp under treatment, but it will usually not be satisfactory at less than 12 in. Individual small frothing-pots have the advantage of providing a rapid discharge for the concentrate, and this apparatus is therefore well adapted to coarse material, to refractory ores, or to preferential flotation. The machines developed at the Junction North mine, Broken Hill, and at the Suan mine, Korea, are of this type.

Another type, corresponding to what was developed at the Arizona Copper Co.'s mill, and at the Central mine at Broken Hill, is shown in Fig. 3. Considerable difference of opinion may arise over the relative merits of the two types represented by Fig. 2 and 3, but as they come into more general use, admitting the comparison of operating results, doubtless one will become popular at the expense of the other. With two pots working side by side, one fitted with jets and the other with an induction-pipe, although the froth had a different appearance, the amount of concentrate coming over seemed to be the same. The apparatus shown in Fig. 3 has the advantage of less complication and practically no loss of head, but the jet-injectors must be carefully designed and the nozzle needs frequent renewal. It is found that 30 to 40-in. head, and $\frac{3}{4}$ to 1-in. nozzles, will give satisfaction. When a rapid froth removal is necessary it is desirable to have small individual pots, either of square or round section. Common oil-barrels make satisfactory pots of this class. With many ores, especially where large tonnages have to be treated, oblong pots would be preferable, the length depending on the tonnage that it is desired to treat in each unit. Very long pots are liable to be unsatisfactory on account of the difficulty of distributing the feed evenly.

One of the latest developments in the Cascade type of machine is shown in Fig. 4. It is covered by the Waterhouse patent. A high-pressure liquid jet is used, both to inject air and to agitate the pulp. This machine will doubtless be elaborated and brought to a high state of metallurgical and mechanical efficiency. A pressure of about 80 lb. is used at the jet, and this pressure can be obtained by using a pump, as seen in the sketch. Since only solution and the finest suspended slime passes through the pump, the wear and tear are not excessive. The frothing-pot is made deep, and is fitted with baffles to confine the violent agitation to the lower part of the vessel. The frothing compartment is usually oblong in shape, and the single pump supplies several jets with high-pressure liquid. To get multiple treatment of the feed, each jet discharges into its individual pocket, which is separated from the succeeding pocket by a partition over which the pulp has to travel in order to reach the final pocket where it is discharged. The flotation reagents should be thoroughly mixed with the pulp before being fed into the separating tank, since it is preferable that the high-pressure liquid used at the jet should carry its proportion of frothing-agent before injection.

The apparatus shown in Fig. 5 presents a radical

change from the preceding types, but its governing principles bring it within the Cascade classification. In this case the stream of fluid that entrains the air and causes the agitation is not a liquid but a vapor, namely, high-pressure steam, the energy of which is utilized by means of a steam-jet injector. On account of the very low thermo-dynamical efficiency of the latter, this machine cannot be economical except when steam has to be used in any case to heat the pulp. In that special field it had a promising future. Oil is mixed with the steam before it strikes the pulp by being drawn into the jet through the small pipe shown in the sketch. It is claimed that better distribution of the oil is obtained in this way, and the claim is well founded, because the heated and atomized oil should certainly possess great covering power. The jet not only forces in the air for the bubbles, but also injects the pulp into the machine. The exact object of this is not clear, but, in the case of multiple-treatment, it would make it possible to have the series of units on the same level, the tailing from one being led into the feed-hopper of the next. This type of machine is covered by the Ohrn patent.

The ideas covered by the Gröndal patent are similar to those embodied in the Ohrn apparatus, except that the oil is forced into the steam-pipe, and the mixed steam and oil then pass to a Koerting steam-jet apparatus where air is drawn in. The steam, oil, and air become thoroughly commingled, and the mixture is led to the bottom of the agitating compartment, which it enters through a funnel-shaped orifice. Unlike the Ohrn machine the pulp is fed direct into the agitating compartment over the mouth of the funnel. After violent agitation in one chamber, resulting from the entry of the steam-oil-air mixture, the pulp passes to another, where the froth and tailing separate and are removed. The method of feeding the pulp direct into the agitating compartment, instead of through the injector, seems to be preferable, except in the case of the multiple treatment above mentioned.

The various machines that have been devised to take advantage of the Cascade principle have been touched upon in the briefest manner, to indicate the lines along which development has proceeded. Many modifications and elaborations will suggest themselves, to suit local conditions, and a wide field for experiment and research lies open to produce a machine possessing a maximum of the strong points of the Cascade process, with a minimum of mechanical complication.

Hitherto, in air-froth flotation practice, metallurgical and mechanical efficiency have followed somewhat divergent paths, but perhaps a by-way, connecting the two, will be suggested by the process as outlined in the preceding pages.

LIFTING MAGNETS are used successfully in recovering iron and steel objects that had been sunk in the water. Recently a Cutler-Hammer type of magnet was applied to lift 420 tons of pig-iron from a wrecked barge in the Tennessee river.

The Oil-Shale Industry

By ARTHUR J. HOSKIN

INTRODUCTION. Much is being said about an American industry in the intermountain region embracing portions of western Colorado, south-western Wyoming, eastern Utah, and a part of Nevada. Anyone living in Salt Lake City or Denver is bound to hear of the petroleum in the shale beds of the so-called Green River series. Not only are the professional promoters busy, but staid business men are becoming interested. Government experts have said so many nice things about the oil-producing character of these shales that the present state of affairs is logical.

Any conversation on this subject is bound to include some reference to the mining and treatment of such shale in Scotland, it being assumed that our American shale is analogous to the Scottish. There being no other source of information concerning the cost and system of operation, many writers of prospectuses have offered lengthy quotations from books descriptive of the Scottish oil-shale industry. Petroleum-shale has been worked successfully in Scotland, France, Germany, and New Zealand for years. American shales will doubtless be worked for centuries to come. At the same time, there may be differences just as significant in oil-bearing shales, the world over, as there are in gold ores, and, in my opinion, conclusions drawn from foreign practice should not be applied prematurely to the Rocky Mountains. We hope the Scottish methods will prove exactly suited to our needs, but we shall not know this for a fact until somebody has demonstrated it upon a commercial scale.

The greatest activity in our new industry is noted along the valley of the Grand river, on the so-called western slope of Colorado. The little towns of De Beque and Grand Valley especially feel the impetus accruing from this new development. These towns are on the main lines of the Denver & Rio Grande and Colorado Midland railroads, which, in this region, operate a joint track.

The general elevation of the productive beds is more than 7500 ft. They are in a vast prairie region, which has been largely neglected because of the inability to irrigate lands that, with the application of water, would prove fertile. Along the water-courses agriculture flourishes. Upon maps this plateau country is called Book Cliffs and Battlement Mesa, these being originally one tableland, now separated by the Grand River valley. The tops of these mesas are almost inaccessible from the riverside, the thick beds of shale having the habit of eroding into precipitous cliffs hundreds of feet high. Mt. Logan is an isolated mass that attracts particular at-

tention from travelers by train. It is just north of De Beque.

THE GEOLOGY of this region is relatively simple. The Green River formation is the most recent of the sedimentary series. It lies, thousands of feet thick, above the Wasatch formation, and this, in turn, overlies the Mesa

COLORADO OIL-SHALE AREA

Verde formation, which is known to be coal-bearing. My description will apply particularly to the Grand Valley, but I wish the reader to remember that the oil-shale is extensive geographically and that activities will spring up, probably, wherever there is convenient access to a railroad. The Denver & Rio Grande railroad traverses

a wide expanse of shale in Utah, and the Union Pacific railroad does the same in Wyoming.

Not all the Green River formation is oil-bearing. For the most part the productive strata are relatively high in the series, in places constituting the top of the tableland. Properties now esteemed most valuable are those so situated as to include the exposure of rich beds upon the faces of cliffs. There is no dearth of such land at present, but there are other economic desiderata that will not long exist in the scramble for ground upon which to establish industrial operations. A fair supply of water seems indispensable. Another essential is accessibility by wagon-road. Roads can be constructed to any property even if they are expensive, but the supply of water is restricted. At present, the search is for thick beds of rich shale lying exposed close to creeks.

Oil-shale is ordinarily discussed in a way to leave an impression that the oil in the rock is ready for extraction. This is, in the main, erroneous. No doubt there are traces of free petroleum in the shale, but the major part of the oil that may be derived from such rock is created during the treatment to which it is subjected. In other words, these sedimentary rocks contain natural substances in proper proportions to bring about, when heated, certain chemical reactions that will produce hydrocarbons. The shale is the compacted ooze of a former fresh-water marsh or sea; it contains the remains of the vegetal and animal life that flourished in that sea. If these organic remains be subjected to heat they will produce oil that is similar, in every way, to the petroleum obtained from wells. There is no alcohol in corn, but the moonshiner knows how to get 'lieker' from it; likewise there is no free oil in shale, although it is a simple matter to put some shale into a gold-miner's retort and produce oil at the gooseneck. The richness of oil-shale, then, depends upon its content of organic remains. In Scotland these substances in the shale go by the name of 'kerogen,' a maker of kerosene. This scientific fact being understood, it is permissible to speak of the shale as 'oil-bearing,' although strictly we should say 'oil-yielding.'

The shale lies nearly flat and is without faulting over large areas. The barren and the enriched strata alternate, and, whereas the thickest and the richest layers are among the most recent, there are frequently thin seams of rich shale in the lower part of the series. These thin seams do not attract attention at present.

A splendid description of these deposits is given in Bulletin 641-F of the U. S. Geological Survey; this, if not out of print, may be obtained gratis upon application at Washington or at the other distributing offices of the Survey, for example, at Denver and in San Francisco. Although the beds lie, as stated, relatively high in the present Green River formation, they probably were originally approximately in the centre of the series.

The productive strata are generally darker in color and lighter in weight than the lean ones. The richer the shale, the less is its specific gravity. The variation in kerogen content does not, however, always correspond to

the color of the rock, rich shale sometimes having a brown instead of a black hue. As the many strata in the face of a cliff are viewed from a distance it is impossible to distinguish the lean from the rich. Although there are apparent differences in shade, it does not follow that the darker streaks represent the richer zones. The richest beds have become sufficiently altered by weathering to present a yellow or gray tint that closely matches the adjacent leaner strata. If, however, a prospector's pick be driven into an outcrop, the shale is quickly differentiated as to grade, because the weathering of the oil-yielding rock does not usually extend more than a fraction of an inch deep.

When one becomes familiar with these shales he learns another characteristic that can often be utilized in long-range investigations, namely, the richer the shale the better it has withstood climatic agencies, so that it often forms a slightly projecting shelf above a sheer cliff of lean rock. The productive strata in weathering do not usually create cliffs nearly as steep as do the leaner strata; consequently they generally outcrop as sloping walls above and perhaps below vertical precipices. This is held to be an economic advantage inasmuch as it will afford a foothold during quarrying operations.

VARIETIES OF SHALE. The oil-yielding shales where they outcrop exhibit two kinds of structure, known as the 'paper' and the 'massive.' The paper shale splits into thin sheets resembling leaves, whence the name Book Cliffs, whereas the massive shale, although showing primary stratification, breaks with an irregular fracture, often conchoidal. Another difference has been asserted, namely, that the paper shale contains more paraffine than the massive. This observation has yet to be confirmed. Horizontal excavations into the paper strata usually encounter the massive shale within a short distance, indicating that the papery characteristic is only a phase of weathering.

It has been found, by preliminary research, that there is a decided difference between the properties of the two kinds of shale when subjected to heat in retorts, the massive shale having a strong tendency to form a pasty mass, especially if heated rapidly, whereas the paper shale remains in separate fragments. This has led to the assumption that a process efficient with one kind may not work successfully with the other; so the question has arisen as to what process, if any, will succeed with both kinds of shale. One company has constructed a still with the intention of handling only the paper shale that outcrops abundantly upon its property. It has succeeded in treating this shale in a small retort and is planning to erect a larger plant. Some concerns are preparing to exploit the massive shale only, while others propose to mix the two kinds as they are quarried or mined.

METHODS OF DISTILLATION. Much research is being devoted to the distillation of the oil-shale. Many persons are positive that the Henderson, Pumpherson, or Young & Fyfe processes, all Scottish, or slight modifications thereof, will prove the ideal treatment for American

A MOUNTAIN OF OIL-SHALE NEAR DE BEQUE, COLORADO

MT. CALLAHAN, GRAND VALLEY, COLORADO

shale. On the other hand there are those who question whether any foreign method will suffice. Anyone who has performed experiments with massive oil-shale in a closed retort will have observed the persistent tendency to caking. Some authorities are emphatic in asserting that this shale will not cake if it be heated gradually, while others claim that the admission of steam to the retort during distillation will prevent caking. It is about this very point that the entire controversy over the treatment of our American oil-shale revolves. If we accept a statement quoted from the memoirs of the Geological Survey of Scotland, to the effect that true oil-shale does not cake when heated to redness in a closed vessel, we may conclude that the Scottish shale must differ from the American shale in this significant particular.

Among the advocates of the non-caking theory are the companies that propose to install a retorting process devised by Otto Stahlman of Salt Lake City. The refining of the crude petroleum from these retorts will be done by the Wells process, developed in the Oklahoma oil-fields. The Pearse Engineering Co. of New York controls rights to a modified Scottish process that is being adapted to the Rocky Mountain shales. In its principle of operation it differs little from the foreign methods.

The main feature of all the Scottish retorts is a vertical and rather slender furnace, oblong or cylindrical in cross-section, flaring slightly downward and operated without admission of air. The upper or distillation half of each retort is constructed of steel and is heated from without, the volatile products discharging together into large pipes leading from the top to condensers. The lower portion of each retort is of brick; within this chamber the fixed carbon is burned, in the presence of steam, to generate illuminating gas and ammonia, these products representing the main revenues from the Scotch industry. The shale is fed and discharged continuously or nearly so. The retorts are arranged in batteries or 'benches' of 64 to 80 units. The petroleum, collected as a single product from the condensers, is piped into the refining departments for fractionation. Such plants are expensive, one unit of the Pumphierston retort, including its condenser, ammonia scrubber, and tanks, costing approximately \$1700, and having a capacity of only four to five tons of shale per day. This cost does not include the refining. The refining plants are of the type found in petroleum districts.

L. F. Chew of Denver is experimenting with an apparatus that is a modification of a simple gas-producer. In his process, the crushed shale is fed continuously at the top of a vertical brick-lined steel retort. Heat is furnished by the combustion of the fixed carbon of the shale itself at the bottom of the furnace. The spent shale discharges continuously through a shaking grate. It is light in color in contrast with the residual shale drawn from retorts that do not consume the fixed carbon. In practically every other American process only the volatile matter is removed during distillation. In the method just described the incandescent zone extends upward from the grate about 18 inches. The volatile matter is

drawn off at the top by suction and is collected as one product.

A Denver company has built a large distillation unit patterned after a McDougall roaster familiar to copper metallurgists. This machine has four distillation chambers containing revolving rakes, each compartment lying above another compartment within which heat is generated by the burning of hydrocarbon vapors injected through burners at one side, the gases of combustion escaping at the opposite side. Crushed shale passes across the decks in alternating radial directions precisely as in an ore-roaster. It is planned to derive different volatile products from each of the four distillation chambers, the temperature of the shale being raised successively at each stage. This process was developed by Messrs. Fefelle and Wingett.

Among the processes originating in Denver is one bearing the name of its inventor, J. H. Galloupe. The shale, after being crushed to one-quarter inch, is fed continuously into the upper end of an inclined (30°) steel retort through which it travels at a rate that will cause the spent shale to discharge at the lower end in about six minutes. The retort is 24 ft. long and 4 ft. wide, and has a rated capacity of 50 tons per 24 hours. In cross-section the bottom side of the retort appears as the arc of a circle struck from the centre of a longitudinal oscillating shaft placed near the top of the retort, which, in cross-section, is an inverted V. Numerous scraper-arms protrude from this shaft. As the shaft moves slowly back and forth, these arms gently but firmly move the thin layer of shale on the floor, causing it to roll or slide forward. The retort is divided, by transverse partitions, into numerous compartments, the partitions not quite reaching the floor. Heat is applied from a fire-box at the lower end of the retort, the flame and hot gases of combustion passing longitudinally beneath the retort and discharging into a flue at the upper end. Pipes lead off from each compartment to separate condensing-members. The accompanying photograph shows that the cooling was done by air. This unit had a capacity of only 15 tons daily, but the commercial units will, as said, handle 100 tons. No air is admitted to the retort.

Numerous other processes are coming into notice, but, so far as I am able to ascertain, they are either unimportant modifications of the Scotch methods or they do not possess sufficient merit to warrant critical investigation. The only process that thus far has been installed in the Colorado shale-field—as previously mentioned—is an adaptation of the Henderson. A 12-ton unit was built by Messrs. Richards and Flynn upon property about 25 miles north-west of De Beque and was operated successfully last summer and fall upon paper shale.

It will be noted that some processes simply distill the hydrocarbons from the shale as a single product that must subsequently be subjected to re-distillation just as is done with petroleum from wells. Other processes perform the initial distillation and fractionation in one stage. I have been told that there has never been one of

these that succeeded, although there have been many attempts in this direction.

FRACTIONATION. The crude oil derived from shale may be fractionated into numberless products. Most of the companies propose to make only a few shipping products, such as gasoline, kerosene, lubricating oil, wax, and residuum. The operators who install the simple distillation methods will rely upon marketing the crude, or they must erect complete refineries in conjunction with their retorting plants. If the majority of the companies proceed upon the plan of manufacturing only crude oil, it would seem that a splendid opening is afforded for the establishment of custom refineries.

Transportation of the liquid products from the retorting-plants to the railroads will probably be done by motor-trucks with large tanks. Pipe-lines for the delivery of the gasoline and kerosene would be feasible, since all the shale-plants will be at altitudes higher than the railroads. Crude oil and residuum cannot be thus transported for the reason that they are too heavily charged with paraffine, which would freeze in the pipe.

HYDROCARBON PRODUCTS. A good idea as to the petroleum contents of the shale may be obtained by reading Bulletin 641-F, already mentioned. Many individuals and companies have had tests made by professional chemists, and these tally with the results reported by the Government experts.

A run made by a prominent Denver chemist upon shale taken about 12 miles north of De Beque showed a total oil content of 46 gallons per ton, the specific gravity being 0.91, equivalent to 24°B. It is proper to remark that it has become the custom to rate oil-shales by the number of gallons of crude oil derived from one ton. Shale of the grade just cited will yield about 17½% crude oil. Upon fractional distillation, the 'crude' from this sample yielded 13.1% gasoline, 45°B., to 150°C.; 38.1% kerosene, 35°B., to 300°C.; and 47.5% residuum, 16°B., to 400°C.

A test made by a refining company in Kansas showed 48 gal. crude per ton of shale, 31.8°B., to 360° C. In re-distillation of this crude, the following was obtained: 15% benzine, 55°B., to 102° C.; 10% distillate, 41.7°B., to 132°C.; 20% gas-oil, 34°B., to 194°C.; 25% heavy oil, 25.8°B., to 260°C.; 28% residuum, 18.6°B., to 360°C. This report showed the crude to contain 18.6% heavy wax or grease-stock and 25.8% wax-distillate.

An investigator at Salt Lake City tested a large sample of De Beque shale and reported a recovery of 54.25 gal. per ton. The average temperature of the charge was 525°C. The crude, upon fractionation, yielded 1.5% naphtha to 150°C.; 5% light oil to 200°C.; 16% heavy oil to 250°C.; 16% fuel-oil to 300°C.; the remainder

being lubricating oil to 350°C. A laboratory in Kansas City has made many tests and sums up its findings by stating that the average shale will yield, per ton, 5 gal. gasoline, 25 gal. kerosene, 2 lb. benzol, ½ lb. cresol, 100 lb. ammonium sulphate, ¼ lb. phenol, and 10 lb. wax.

A sample of shale-oil sent to an Oklahoma refinery, upon fractionation, yielded 15% gasoline; 16% naphtha, benzine, and kerosene; 43% lubricating oil; and 10% paraffine.

From such returns we observe that the shale is variable

MINING OIL-SHALE NEAR GRAND VALLEY, COLORADO

both in total contents and in the fractions that may be made. Of course, it is not strictly proper to compare these various results, for the reason that the shales and the crude oils were probably handled quite differently by the several chemists. Differing manners of applying the heat during retorting will produce varying results from the same shale, while the splitting of the fractions at different temperatures will likewise make wide variations in the quantities of the several products. Here is a new field for the petroleum technologist.

PROSPECTIVE DEVELOPMENT. There will be great activity this year in the development and equipment of oil-shale properties, but it is improbable that more than a

few enterprises will get under way on a commercial scale. This is not said in a pessimistic spirit, by any means, but because I appreciate the difficulties confronting every operator in this new industry. Since nobody thus far has operated upon a practical scale in America, we lack knowledge regarding the best methods of procedure in mining as well as in retorting. We have no standard processes generally acceptable. If all managers could feel certain that foreign methods would prove efficient, progress would be rapid. The very fact that so many persons are bringing out processes differing from the Scotch is indicative that there will be considerable experimentation. Several companies are arranging to erect working units based upon new inventions. It is unlikely that all these schemes will prove successful and therefore one may anticipate that some disappointments will be experienced by the pioneers. Men who are in the lead to the extent of risking capital deserve the highest respect from their fellows and followers. Somebody must make the start. Every one of the new schemes has been tested upon a small scale, but, as any engineer knows, this is no assurance that it will prove successful upon a commercial scale. The net result of this year's efforts will be progress in the industry. Mistakes made this year will be of incalculable benefit in guiding further advance.

COST OF EQUIPMENT. When it comes to the expense of equipment, we are compelled to guess. The first cost varies tremendously. Some of the proposed schemes call for ten times as much capital as others. Any manager is willing to pay the highest figure if thereby he can feel assured of the best apparatus and the most profitable result. It may be stated roughly that the initial cost of a 100-ton retort and refinery, including the requisite mining, crushing, grinding, and condensing equipment, will be anywhere from \$50,000 to \$500,000. Before one can offer estimates of cost, there should be some decision as to the proper size of such a plant. Figures have been quoted publicly for plants of a capacity of 1000 tons per day. Such a capacity is perhaps the ideal to which the companies should strive, but, in an industry as new as this, it would seem improper to build a plant to treat 1000 tons daily until we know more about the operation of the processes involved. It is advisable to make the first equipment upon a modest scale, say, of only 100 tons daily in the retorting department, with provision for expansion just as soon as we know how to adjust and operate the selected processes. The crushing and grinding department of a plant can be designed at the start to handle the proposed ultimate tonnage, which may be 1000 tons or 500 tons. Several companies have made plans for plants of 500 tons daily capacity. They propose to put in retorting units to handle only 100 tons per day and to experiment with these until the managers have learned how to operate them perfectly, when additional units can be added to bring the capacity to the 500 tons. Naturally, the cost of handling shale upon a 100-ton basis will considerably exceed the cost per ton when the ultimate capacity is attained. However, the greater operating expense will be war-

ranted if it prevent large losses due to the premature erection of unsuccessful plants.

The equipment for mining or quarrying, at the start, will be cheap. As already explained, the shale-beds, in most instances, outcrop high above the foot of the cliff where retorting plants would logically be erected, and the formation lies almost flat. In most cases, the excavation of the 'ore' can proceed for a considerable time in open workings along the precipitous slope. Eventually, it will be necessary to drive into the hills and to secure the shale by underground methods, probably by a modification of the room-and-pillar system common in coal mining. There are a few properties in which the overburden may be stripped and the shale mined continuously by open methods. In this kind of mining there will be no hoisting or pumping. Ventilation underground will require machinery as the workings are extended. This kind of ground will drill easily by hand, but the cost can be lessened by using machines. Power for driving fans and compressors will be generated by internal-combustion engines utilizing 'home-made' fuel.

One thing that gives considerable concern to each prospective operator is the problem of getting the raw shale from the mine to the plant to be erected at the foot of the cliff. Aerial tramways are planned by two companies. Others believe they will succeed in dropping the broken shale down the steep walls of the gulches in such fashion as to render it readily recoverable by shoveling and tramping.

COSTS OF OPERATION. From the foregoing it is apparent that an estimate of the average operating cost will not be possible until a decision is reached concerning the scale of retorting, the method of excavation, the manner of lowering the shale from the mine to the plant, the processes used in distillation and refining, the number of shipping products manufactured, and the scheme for delivering these products to the railroad.

Machinery for crushing and grinding will vary, some processes requiring relatively fine grinding while others call for coarse crushing only. In some of the Scottish methods the shale is crushed only to 6-inch size, whereas in at least one American process it must be reduced to quarter-inch. Oil-shale behaves differently from ordinary shale in crushers and pulverizers, being much tougher and having a tendency to clog the machinery. All kinds of comminuting apparatus are being tested, so that it is impossible to arrive at even rough averages for the probable cost of crushing. This item of expense may vary from 7 to 35c. per ton.

There is more assurance regarding the probable cost of mining. Estimates based upon an initial output of 100 tons per 8-hour day place the cost of securing the shale from outcropping ledges at from 40 to 50c. per ton. These figures including the breaking of the rock and lowering it to the refinery-sites. When the shale is mined underground the cost may be 20c. higher per ton.

The cost of distillation has been estimated between 12 and 65c. per ton; that of condensation depends upon the number of products made and may run from 9 to 17c.

per ton of shale treated. In processes employing separate retorting and refining plants, the item of refining is important, for it may run from 25c. to \$1. If by-products or materials other than ordinary gasoline, kerosene, lubricating oils, greases, and wax are to be manufactured, one must allow additional expense for the apparatus and chemicals required.

The cost of fuel will differ according to the process. One company expects to mine an extra ton of shale to be burned on grates in driving off volatile matter from four

the yield of ammonium sulphate constitutes an important factor in the profit. It is said that where the yield of oil is low that of ammonia is high. The nitrogen content is therefore of more significance in Scottish works than the kerogen. To the American way of thinking, it appears that the Scottish profit is dependent largely upon the by-product from the oil-recovery.

American oil-shales invariably yield ammonia upon distillation, and it is probable that every company will contrive to make a commercial product from this variable chemical. Various investigators have reported other by-products, such as potash, gold, silver, and even platinum,

THE CHIEW APPARATUS

THE FLYNN & RICHARDS RETORT

tons of the same shale. Others intend to conserve the fixed gases that come off first from the shale during distillation and to burn these in the fire-box. If the gases do not supply sufficient heat, they will be augmented by raw shale or possibly by coal or wood. Another suggestion is to manufacture water-gas from the residual carbon in the hot spent shale from the retorts, this gas to be mixed with the non-condensable gases coming from the retorts. In practically every instance, the operator plans to get his fuel from the shale itself.

BY-PRODUCTS. In Scotland the quantity of crude oil retorted seldom exceeds 30 gal. per ton of shale, and it is a regular practice to treat rock yielding as little as 10 to 15 gallons. In our American shale-field nobody expects to handle shale running below 30 gal., at least for some years to come. An average grade for the shale deposits upon which activities are based in the near future would be one barrel, or 42 gal., per ton. In Scotland

in addition to such things as phenol, benzol, cresol, ozokerite, and dye-stuffs. Some of these substances may be recovered from the shale at a profit under prevailing market-prices, but there is doubt regarding the commercial outlook after the War. The spent shale will average 1% K_2O , too little to warrant the necessary expenditure for recovering potash, even at current prices. As to the precious metals, I am skeptical and suggest that samples have been salted unintentionally in the laboratories. A few cents per ton of shale handled might be received from the sale of benzol, cresol, and phenol, but the profit might prove a negative quantity. If it really prove possible to manufacture 10 lb. of ozokerite per ton of shale, as one chemist claims, this single item would offer greater returns than all the other products combined.

In the domestic industry, plans are laid primarily to make but a few primary products, such as motor-spirit, fuel-oil, lubricating oil, and residuum, for all of which

there will continue a steady demand indefinitely. Managers will, no doubt, be awake to the potentialities in by-products and will, in the course of time, make preparations to manufacture such of them as offer a profit.

PROPERTY RIGHTS. It is necessary to make some mention of the legislative troubles confronting future locators of oil-shale land. Up to the present, this kind of land has been located under the ordinary oil-placer regulations, claims being usually of 160 acres each, in the names of eight persons. Bills are pending in Congress looking to future restrictions in the location of all kinds of oil-yielding land. It is likely that Congress will place all non-located oil-shale land in the same general class with ordinary petroleum land, so that future locations will be governed by the same regulations as to acreage and lease royalties as will apply to oil-lands.

A MANUFACTURING INDUSTRY. The operation of an oil-shale plant is a manufacturing proposition. The supply of raw material is abundant and plants can be designed for long service. There is little or no speculation regarding the grade of the raw material because the beds continue reasonably uniform in their content of kerogen over considerable distances. The markets for the products will remain strong for years to come. The supply of motor-fuels, derived from petroleum wells, has been falling steadily behind the needs of the world at large. The uncertainties confronting this industry are primarily in the selection of suitable schemes of treatment, but these will be settled before long by those that have the nerve to make the first moves in the erection of commercial plants.

There is one feature of this business that has not been sufficiently recognized. This is the necessity of placing the technical and practical affairs of the business in the hands of men properly qualified. The remark is often made that we have, in America, too few experts in this line, and this is literally true. At the same time, we have plenty of engineers that have had sufficient experience in branches not widely different from this new business to have given them the foresight and judgment needed for avoiding serious blunders. It is stupid to risk capital in projects that are to be managed by laymen who assume they are capable of handling this business at least as well as a trained engineer. Even with the best available technical advice, companies may experience difficulties at first, but such troubles will be vastly less costly than those to be faced by shortsighted operators unwilling to employ engineers. On the other hand, investors must be on their guard against numerous shysters that pose as experts. The activities of such persons are apparent already.

X-RAY PHOTOGRAPHS may be used to determine the internal condition and deterioration of reinforced concrete. Photographs of slabs several inches thick have shown the condition of the concrete and also of the reinforcing-rods. The injection of a bismuth solution under pressure helps to determine the existence and position of even fine cracks.

Chromite in North Carolina

By JOSEPH HYDE PRATT

*The occurrence of chromite is in the peridotites and allied igneous basic magnesian rocks, or in serpentines that have resulted from their alteration.

The mining of chromite has been attended with uncertainty on account of the pocketly nature of the deposits, for chromite is not found in veins, but in pockets or bunches of varying dimensions, which may or may not be connected with one another, and are limited in extent. The fact that 10 tons or 10,000 tons have been taken from one pocket does not signify that it is still a good deposit, but if a certain pocket has been largely productive, that would serve as a strong indication of the existence of other pockets nearby. Again, if a deposit of this mineral is found near the contact of peridotite with other country rock, and if this peridotite is extensive and the chromite is found in considerable quantity, there is a probability that large deposits will persist in the area.

While chromite is almost universally associated with the peridotites of North Carolina, only in a few localities is it found in quantity. One of the most promising deposits is in Yancey county at Mine Hill, five miles north of Burnsville, the county-seat. The ore is in peridotite, which outcrops on both sides of the road. The work done gives indication that chromite occurs in quantity. The C. C. & O. railroad from Erwin, Tennessee, to Green River station, North Carolina, runs within $3\frac{1}{2}$ miles of the property. A 52% ore can probably be obtained by hand-picking. Associated with the large peridotite area in the vicinity of Webster, Jackson county, chromite has been found abundantly near the contact. It is not proved whether it is to be found in sufficient quantity to make mining profitable. These deposits are from three to five miles from the railroad. Another property is being developed on Big Ivey creek, in Buncombe county, about 16 miles north-west of Asheville and nine miles from the railroad. There is considerable chrome sand on the property, which is readily concentrated, and the concentrate is said to contain 54.09% chromic oxide. The cobbed ore analyzed 48.78% chromic oxide. A promising deposit of chromite occurs in the Balsam Gap peridotite area on both sides of Dark Ridge creek about 175 yards south of the Murphy branch of the Southern railroad. A number of open cuts and pits show the presence of chromite. There is a large quantity of float-ore in the vicinity. All the North Carolinian ores are high in grade. The existence of large deposits has not been conclusively shown, but the four localities mentioned are worthy of investigation.

CREDITS to the Allies totaled \$4,949,400,000 to March 1918. Of this, England received \$2,520,000,000; France, \$1,440,000,000; Italy, \$550,000,000; and Russia, \$325,000,000.

*Abstract: 'Manufacturers Record.'

cause no uniform plan for its exclusion had been followed when the wells were drilled. It was recommended that a campaign of repair be followed, commencing with the plugging of the bottom of two wells, which were probably too deep and therefore causing the main trouble. It was pointed out that if this first step failed to remedy conditions, work at other wells would be required in order to control the 'top' water.

The owners of the two deep wells commenced work as recommended. One of the wells (Alma Jr. No. 2) has been pumped by compressed air for a number of years. It produced about 12,000 bbl. of water per day, with no oil. As soon as repairs began at this well, the air-lines had to be removed. The water-level rose immediately in surrounding wells, which thereupon ceased to produce oil. This made it necessary that the proposed repairs should be made as rapidly as possible. To expedite matters, J. E. Beard, president of the Alma Oil Co., arranged that the State Oil and Gas Supervisor should assume the responsibility of choosing a crew of workmen and of directing the work. A crew from the adjoining Santa Fe property was engaged, and with the co-operation of D. T. Saine, superintendent for the latter concern, repairs proceeded successfully. It is of particular importance to note that several years ago a similar co-operative agreement between the companies had been made, but the efforts to repair the well were unsuccessful at that time.

No new mechanical methods were adopted by the State Mining Bureau in repairing the well, but it was impressed upon all interested parties that the job was difficult and would not be abandoned, no matter how slow the progress might be. It was recognized that the upward flow of water through about 100 ft. of loose unconsolidated sand could not be stopped until a plug was placed below the sand and in the impervious clay-stratum overlying the water-bearing sand. Such conditions held out no promise of speedy work. The old perforated casing was removed from the well and unperforated 7½-in. casing was inserted until it was stopped by the heaving and caving sand at a depth of 702 ft. The casing was carried through the loose sand to a depth of 789 ft. by introducing sufficient clay to fill the interstices of the sand and thus prevent further caving of the sides of the hole. This took about four months and required 1000 cu. yd. of clay. The casing could not be carried deeper than 789 ft., but the continued use of mud permitted the hole to be cleared to a depth of 886 ft., proving that the original log shown in the cross-section was in error to the extent of 60 ft. This required 100 cu. yd. of clay in addition to the amount already used. The clay was shoveled into the top of the casing and a steady stream of water was also kept running into the well. The tools were kept swinging at the bottom of the open hole, mixing the mud and assisting the water to carry it into the loose sand. The casing had to be raised and lowered to keep it free. A system of mixing the mud at the surface and pumping it into the hole would have

been quicker, but the necessary equipment was not available.

Within a week after mud was started into the well, it began to show in the fluid pumped from surrounding wells, as much as a quarter of a mile away, both up and down the dip of the strata. As fast as neighboring wells showed mud, they were shut-down, so that the mud would not be drawn away unnecessarily from the well under repair. The well was plugged between depths of 886 and 702 ft. The plugging was done by stages from the bottom. The general plan was to 'shoot' away the casing in impervious clay streaks and to place solid cement plugs. Between the clay streaks the casing was not 'shot' ordinarily. Instead a filling of clay, cobbles, and rope was tamped into the hole. Each cement plug required from 10 to 15 sacks of cement. Five 'shots' of 30 to 50 lb. of 60% dynamite each were exploded. A heaving-plug was set in the casing at a depth of 702 ft., and the casing was perforated between 684 and 702 feet.

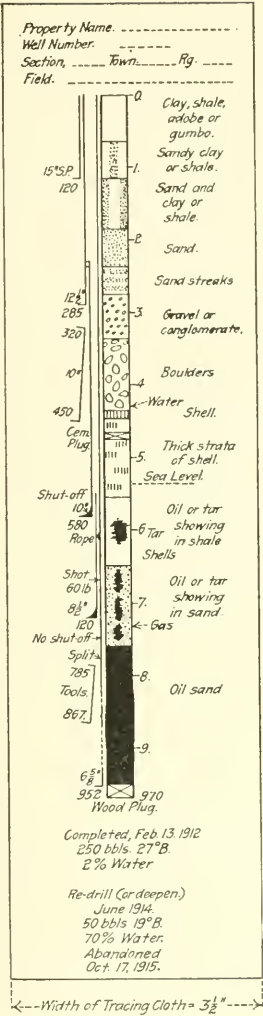

The total cost of the work was as follows:

Labor (March 1 to September 17).....	\$4,444.48
Lumber	180.05
Material, miscellaneous	562.40
General expense	231.20
Hauling clay	2,499.14
	\$7,917.27

The condition of wells in the vicinity, both before and since repairs, is shown by the following table:

No.	ALMA JR.		After repairs	
	Oil bbl.	Water bbl.	Oil bbl.	Water bbl.
1	trace	150	7	00
2	00	12,000	trace	100
5	trace	200	10	trace
11	"	250	7	40
12	"	200	10	25
1	3	32	4	10
PETROLEUM DEVELOPMENT CO. (SANTA FE)				
2	00	1,440	(not yet rigged for pumping)	
6	5	250	4	20
10	5	400	5	10
14	5	5	5	10
18	7	1,000	7	25
Total	25	15,927	59	240

The saving in operating expense and fuel at the compressor-plants, plus the increased production from affected wells, amounts to about \$150 per day, which is a yearly profit of nearly 700% on the expenditure for repairs. The profit would have been much greater had the well been repaired at first before the compressor-plants were built. It may surprise the average reader, holding the common belief that large oil companies are highly efficient, to learn that comparatively few concerns take full advantage of technical knowledge. The State Mining Bureau has, during the past year, called the attention of all concerns having an annual oil production of more than a million barrels to the advantage and

The kind of plugs (cement, wood, or other) must be noted, as shown at left, and bottom.

economy of thoroughly organized technical staffs authorized to direct their development work. A gratifying improvement has been noted, but some companies do not yet realize the importance of this matter. The public has always been concerned in the protection of our oil-fields, and at present the war-time needs make it obligatory that the utmost efforts toward economy of labor and material be exerted. The next annual report of the State Oil and Gas Supervisor will therefore classify all the large producers with reference to their technical organization. The law makes it mandatory for the State Mining Bureau to approve specifications and inspect all work at new wells, and it is therefore impossible immediately to investigate and solve the many old prob-

STREAM OF WATER PUMPED FROM ONE OF THE AFFECTED WELLS BEFORE REMEDIAL WORK WAS DONE

lems similar to the one herein described. There remains in the oil business a broad field of usefulness for competent engineers engaged in private practice or in the regular employ of oil companies.

ACCORDING to a preliminary report issued by the U. S. Bureau of the Census, American-owned merchant vessels of five tons net register or over, of all classes, operating during the year 1916 on the coast or inland waters of the United States, including Alaska, or between ports of the United States and foreign countries, numbered 37,894 and had a total gross tonnage of 12,250,000. Gross tonnage is calculated by dividing entire internal capacity, in cubic feet, by 100. The geographical distribution of this gross tonnage was as follows: Atlantic Coast and Gulf of Mexico, 6,509,000; Mississippi river and its tributaries, 1,621,000; Pacific Coast, including Alaska, 1,186,000; Great Lakes and St. Lawrence river, 2,738,000; canals and other inland waters, 196,000. The distribution according to method of propulsion was: Steam and other power, 6,098,000; sail, 1,089,000; unrigged, 5,063,000. The increase in vessels compared to 1906 was only 1 1/2%, and the gross tonnage shows a decrease amounting to 5%. This is caused by the marked reduction in number and tonnage of sailing vessels and in tonnage of unrigged craft. The former show a decrease in number from 7131 to 2979, or 58%, and in gross tonnage from 1,704,000 to 1,089,000, or 36%.

GOLD OUTPUT of Rand in February was 659,000 oz., compared with 721,000 oz. a year ago.

Roasting Zinc Ore for Leaching

By FLOYD DIXIE JAMES

*Zinc sulphide ore is roasted to convert the zinc into the oxide or sulphate so that it can be dissolved in dilute sulphuric-acid solution. There are two schemes available: (1) an oxidizing roast, and (2) a sulphatizing roast. The object of the oxidizing roast is to completely eliminate the sulphur, the zinc remaining as oxide. The object of the sulphatizing roast is to oxidize the zinc entirely to sulphate. Zinc oxide is readily soluble in sulphuric-acid solution, and zinc sulphate is soluble in water. In the early work on the hydrometallurgy of zinc, the sulphatizing roast was tried, because the zinc sulphate formed was soluble in water, but great difficulty was experienced in converting all of the zinc to the sulphate, and the recovery was low. The existing commercial plants appear to have started to effect a complete de-sulphurization or 'dead roast', that is, to convert all of the zinc to zinc oxide. This has always been the aim of the retort smelters, so that information and data are readily obtainable along this line. The processes now in use seem to have been based on the application of the oxidizing roast, because the metallurgists could figure on the results to be expected from it. As the plants are giving the anticipated results, their metallurgists are experimenting with the sulphatizing roast, as this would lower the cost of treatment, and materially lessen the acid-consumption per pound of zinc.

Regardless of which roasted product may be desired, the complete elimination of sulphide-sulphur is essential. Zinc sulphide is practically insoluble in dilute sulphuric-acid solutions, and each pound of sulphur, present as sulphide in combination with zinc, renders two pounds of zinc insoluble.

Care must be used in eliminating it, for at elevated temperatures zinc ferrite is said to form. Zinc ferrite causes no difficulties in retort-smelting, as it requires only a little extra heat to decompose it, but in hydrometallurgical processes it may prove fatal, because, being insoluble in dilute acids, it causes a large loss of zinc. Some metallurgists assert that zinc ferrite forms at a low temperature, and they regulate the roasting temperature accordingly, while others assert that high temperature is required to form it.

The length of time that the ore is roasted is important as well as the temperature. The longer and harder an ore is roasted the denser will be the resulting product, on account of the molecular stresses which are set up. The physical condition of the ore plays an important part in the ease of solubility of the zinc from the roasted ore. This may increase the time of leaching, or it may

cause a lower recovery, for some of the zinc may have been rendered insoluble. One writer† gives zinc ferrite as 20% soluble in cold 10% sulphuric acid. W. McA. Johnson‡ says that, by heating zinc ferrite at 1300° C. for 12 hours, he obtained a hard dense zinc ferrite, which was practically inert chemically. The ferrite used by the former writer could not have been so strongly ignited.

It is known that ignition renders zinc oxides less easily soluble in caustic solution, and time and temperature play a large part in the degree of solubility. This should also hold for other solvents. Therefore, when roasting for hydrometallurgical purposes, the temperature apparently should be held as low as is consistent with good work, and the roasting should be as rapid as possible. The conclusion from this is that the possibility of forming zinc ferrite is not the only reason for the careful regulation of the conditions of roasting. The present tendency toward the sulphate roast makes it beneficial to have iron in the ore, as it is difficult to obtain a good sulphate-roast on a blende that is low in iron. While the iron aids in sulphate roasting, it also makes the production of zinc ferrite possible, unless the temperature can be controlled to prevent it. Such control of the conditions of roasting as will produce a maximum of zinc sulphate, and at the same time avoid an excessive formation of zinc ferrite, or leave zinc sulphide unoxidized, will admit of treating any of the low-grade complex ores successfully. In my experiments I finished some of the roasting tests at a high temperature to bake the iron and to render it insoluble in dilute sulphuric acid. This was easily done; but as some of the zinc apparently was rendered insoluble, and as it was found that a considerable quantity of ferric iron was not harmful in electrolysis, this method was abandoned. A small amount of iron is necessary in the solution during purification to remove the arsenic and antimony. It is more effective if it is dissolved from the ore than if produced by throwing in scrap.

The practice of using carbon to aid de-sulphurization in the roasting-furnace does not appear to have a place in roasting for subsequent leaching. The carbon, at the low temperature of a roaster, will decompose zinc sulphate according to the equation:

This would defeat the purpose, as a maximum amount of zinc sulphate is desired. The effect of carbon on zinc ferrite at the temperature of the roaster I do not know.

*Abstract: 'The Hydrometallurgy and Electrolytic Precipitation of Zinc'; Bulletin Missouri School of Mines and Metallurgy, 1917.

Coal added to an ore which had been roasted to a low-sulphur content gave a roasted product which yielded a better recovery by leaching than an ore not treated with coal. When the loss of zinc in roasting was investigated, the ore to which coal had been added showed a loss about three times as great as in the regular roast. The gain in recovery on leaching was slight.

LEACHING OF THE ORE. The idea was to determine the maximum percentage of zinc that could be leached under the most favorable conditions. The recoveries obtained show what is possible under ideal rather than commercial conditions. Whether or not these can be duplicated on a commercial scale, I cannot say, but under favorable conditions they should be. The exact amount of acid solution was calculated and added. After the ore and solution had been agitated a sufficient length of time the solution was filtered from the residue. Dilute sulphuric-acid solutions were used for all the leaching tests. After solutions of various strengths had been tried, it was decided that 10% was best, as it gave the zinc concentration desired for the electrolytic cells, and decreased the bulk of solution to be handled. A more dilute solution gave the same recovery, but it had the disadvantage of producing an electrolyte low in zinc and a large volume to be handled. Very little work was done with stronger solutions, as they did not give promising results.

In the first series the agitation was continued for 24 hours. The idea was to extract all the zinc possible. The time given was found to be in excess of that required. The ore was ground to pass a 100-mesh screen. It was thought that at 100 mesh all the soluble zinc would be exposed to the action of the acid. The results of the leaching on finely ground calcine and that on the calcine as it came from the roaster did not show much difference in extraction. The ore appeared to have been rendered porous enough by roasting so that the acid could penetrate it and extract all the soluble zinc.

PURIFICATION OF THE SOLUTION. The most important step in the electrolytic-zinc process appears to be the purification of the solution. Until recently all of the processes in vogue attempted to deposit the zinc from impure solutions, and were failures. Now, however, by using practically the same process, but purifying the solution before electrolysis, favorable results have been attained and large successful plants are in operation. It appears that an exceedingly pure solution is essential for success. The presence of some impurities, even in small proportions, will not only give an impure deposit of metal, but will prevent the deposition of zinc in a smooth coherent cathode. The solution from the leached calcine may contain the following impurities: arsenic, antimony, iron, manganese, copper, and cadmium, together with others of less importance.

The iron is the first impurity to be removed. It is present mainly in the ferrous state, and must be oxidized to the ferric condition so that it may be precipitated and removed as ferric hydroxide. Various oxidizing agents can be used. Manganese di-oxide is generally added to oxidize the iron. The oxidation takes place according to the following reaction:

The free acid in the solution must be neutralized before the iron can be precipitated as the hydroxide. Limestone, milk of lime, high-grade roasted zinc ore, or zinc oxide can be used to neutralize the free acid and precipitate the iron. The method of leaching can be so arranged as to run the solution through a fresh charge of ore. This will use up the free acid, while the ferric hydroxide will be precipitated from the solution when it becomes slightly alkaline. When milk of lime is used the following reaction takes place:

The insoluble ferric hydroxide is precipitated, and carries with it the arsenic and antimony present, the freshly precipitated ferric hydroxide forming an insoluble compound with arsenic oxide. The antimony behaves in a similar manner. The solution contains copper, cadmium, and other metals, and these are removed with some form of metallic zinc. Some of the metals are replaced by zinc as shown by the following reactions:

The filtered solution should be sufficiently pure for use in the electrolytic cells. In my tests the procedure was as follows: The iron was oxidized in three ways: (1) By forcing air through the solution; (2) by passing ozone through the solution; (3) by addition of manganese di-oxide. In the first method compressed air was passed through the solution for some time, and the remainder of the purification carried out in the regular manner. In the second, ozone was passed through the solution slowly. Considerable difficulty was experienced in handling the ozone. The machine was rather small and the work was done under difficulties. The results cannot be taken as final. Ozone is a cheap and efficient oxidizing agent, and when properly applied, it seems that it should prove the cheapest and most effective method of oxidizing the iron in solutions that are free from manganese. In the third method manganese di-oxide was added to the solution and thoroughly agitated with compressed air. This gave very satisfactory results.

The solution was filtered, and the copper, cadmium, and other metals were precipitated from the solution by means of zinc-dust, which was added to the solution and thoroughly agitated. Better results were obtained when the solution was allowed to drop slowly through a filter containing zinc-dust. It is thought that this was due to the greater length of time that the solution was in contact with the zinc. Zinc-scrap and shaving have been used to remove copper, and other metals, but zinc-dust has been found to be the most speedy and efficient reagent for this purpose. The solution was then filtered to remove the excess zinc-dust and the metals which had been thrown out of solution. This filtered solution should be pure enough for the electrolytic cells.

Source of Nitrate and Iodine

By A. W. ALLEN

Chile produces two substances having strangely contrasting utility: nitrate of soda, used for making munitions, and iodine, the base of iodoform, which is perhaps the best known wound-healing antiseptic. They are found together in one of Nature's greatest chemical storehouses, the Atacama desert. Of the two the nitrate is more widely employed, for in times of peace it is used extensively as a fertilizer and also in sulphuric-acid manufacture. In the period of reconstruction that will follow the War it will play an important part in giving renewed impetus to agriculture.

The deposits of the raw material, constituting Chile's most valuable asset, and yielding her an immense revenue, have caused war and have aided war. Provocative action on Bolivia's part in 1879, interpreted as an interference with Chilean interests at Antofagasta, then a Bolivian town, led to a severance of diplomatic relations. In the war that ensued Peru joined Bolivia against Chile, but Peru ultimately lost the province of Tarapacá, and Bolivia lost her only seaport. Chile gained an immense territory containing about 500 square miles of nitrate deposits. The nitrate pampa, as the desert is called, has no rival for desolate dreariness. It never rains and all the lines of erosion are always dry. Of vegetable or animal life there is nothing to be seen; but the pampa's desolation and monotonously dry climate is its salvation, because a single shower of rain would play havoc, and the world's principal deposit of nitrate would be quickly lost by seepage into a waste of worthless sand. Many theories have been advanced to account for the deposit. Some maintain that it has been caused by the action of bacteria; others that original deposits of guano or sea-weed have been subjected to the decomposing action of salt water during a subsequent submergence under the sea. It is doubtful whether any unanimously acceptable theory will ever be advanced. The fact remains, however, that this huge deposit is estimated to contain about 250,000,000 tons of sodium nitrate and about 250,000 tons of iodine. This supply is enough to make munitions and antiseptics, even at the present rate of consumption, for another century. The nitrate and iodine-bearing rock or 'caliche' is found in horizontal layers a foot or more in thickness, often on the very surface, but usually at a depth varying from 5 to 30 ft. It commonly occurs in the form of a brick-red stone, somewhat resembling granite, and often sparkling with crystals of nitrate, but other colors are also seen. The 'caliche,' as it is called, is exceedingly friable, and falls to pieces after prolonged exposure to the air. If taken outside its native habitat, it absorbs moisture with great avidity and 'weeps' its soluble contents.

Methods for the recovery of the nitrate usually follow conservative old-fashioned lines, but recent research is pointing the way to more economical methods. The broken caliche is 'cooked' in large vats, and the clarified liquor distributed to shallow 'bateas,' where the nitrate is allowed to crystallize. The iodine is then recovered from the remaining 'mother liquor' by means of a precipitant made from native sulphur and coal.

Over a hundred nitrate plants are in operation, the larger number having a normal capacity of about 800 tons of caliche per day. Over narrow-gauge service-

NITRATE AND IODINE WORKS, CHILE

railroads life pulsates through the mummified landscape; a never-ending stream of oil-tanks and supply trains goes from the coast to the pampa region; and platform cars stacked with nitrate returns from the pampa to the coast. "It all goes to the Germans," said a well-known Mejillones wit to me; and then, seeing that the jest had not miscarried, he added, "but in a form they don't like." This may not be strictly true, because some of Germany's 'neutral' neighbors imported largely increased amounts of nitrate at the outbreak of war, ostensibly for agricultural purposes, but at a rate suggesting the advisability of putting the crops on rations to prevent over-indulgence in fixed nitrogen.

After an apparent realization of the existing conditions of supply in the United States an appropriation of \$20,000,000 was voted by Congress over a year ago to provide a plant to extract nitrogen from the air. The scheme, for reasons not hard to understand, was long blocked by certain chemists and others who tried to have the money diverted from its intended purpose to experimental investigations. Entire dependence on Chile for nitrate is still the sad case of this country and is likely to remain so for some time to come.

REVIEW OF MINING

NEW YORK

Employment and Labor; Co-operation and Benefits.

The New York Section of the American Institute of Mining Engineers met at the Engineers Club on March 26 and discussed labor and employment problems. Sidney Jennings, president of the Institute, and one of the vice-presidents of the U. S. Smelting, Refining & Mining Co., outlined the evolution of company laws from the inception of the idea in early Roman times, cited the drastic anti-company legislation passed during periods of mediaeval and modern English history, and discussed the application of the principles involved at the present date. It was pointed out that the immense growth of centralized business has tended to estrange personal co-operation between employer and employee. Operations are now carried out on so vast a scale that the manager or superintendent of a property or works may know personally very few of the men on his payroll. This has led to a lack of understanding. A plea was made for the better utilization of prominent trades-union leaders in the handling of employment problems by large concerns; and the appointment of an employment agent or manager to engage and discharge all employees, and so minimize the effect of personal friction and misunderstanding between the latter and their shift-bosses. J. Parke Channing, of the Miami Copper Co., compared labor conditions here and in England, and dwelt on the difficulty of the foreign labor problem in the United States—a complex phase of the situation not encountered in England. Attention was directed to the post-bellum reconstruction policy of the British Labor party in its tentative demands for (1) a national minimum wage, (2) the democratic control of all industry, and (3) the re-modeling of national finance so that all excess wealth could be utilized for the common good. These demands indicate the temper of the masses and, although a modification of the terms may be expected, the fundamental ideas will doubtless find repetition among the same section of the community in the United States. Trades unionism is little understood, and it is inadvisable to ignore the obvious fact that the claims and interests of employers and employee are usually diametrically opposed. Compromise might help to reach an understanding, but education is imperatively necessary on both sides. The human phase of engineering should form a part of every educational curriculum to train men for positions of responsibility. Walter Douglas, of the Phelps-Dodge Corporation, dwelt at length on the efforts being made, especially at the Copper Queen property, to attract and retain labor by means of material and monetary advantages. A service bonus of \$100 is paid to all employees after they have been in the company's service for over a year. A pension amounting to 2% of all wages earned is paid after 15 years' service, or if retirement is necessary on account of physical incapacity. Workers may retire at 60 and claim the same privilege. The maximum amount payable under the scheme is \$1000. The cost of living at Bisbee has been reduced by well-organized and efficiently-managed company stores. Hospital dues amount to only \$2 per month as a maximum expense to cover all possible medical attention for a married man, his wife, and children. Unions are recognized by the authorities, but no

possible excuse is accepted for disloyalty to the Government or repudiation of a contract when once entered into. Grievances which cannot be amicably settled at the mine are taken to a Federal Mediator. Edwin Ludlow, vice-president of the Lehigh Coal & Navigation Co., dealt largely with the position of labor in the anthracite coal region of Pennsylvania during the past 15 years. Serious labor troubles in 1902 led to the appointment of what was known as the Anthracite Strike Commission, whose findings have materially aided industrial peace and a better understanding between employer and employee since that date. Failing a settlement of the dispute on the property it was agreed that the matter should be laid before a Board of Conciliation, which was empowered to grant or refuse the request. If the Board considered the request equitable it was granted; if unreasonable, it was refused. This excellent provision eliminated the unnecessary discussion which inevitably follows all attempts at bargaining; and indicated that the more moderate the demand the greater likelihood of its acceptance. A second salutary condition was insisted upon in that no grievance could be considered, much less remedied, as long as the men did not return to work. The objection to this on the part of employees that the findings of the Board might be delayed unreasonably was effectively met by a counter-proposition on the part of the employers that all awards would be retro-active, and would date from the time that the complaint or grievance was lodged. The result of these eminently satisfactory conditions is that the anthracite field is now able to meet labor troubles with confidence as to an ultimate solution acceptable to both parties. Of the 150,000 workers in the region, all nationalities are represented except Orientals, and these would be welcomed. The better class of workmen are encouraged to join the unions, as it is found that their influence tends to moderate or allay the socialistic opinions of the more radical and less responsible element. The I. W. W. have now no hold on the district, and would receive no welcome if they returned.

A wage increase of 15% among day laborers in its plants has been decided by the U. S. Steel Corporation, as announced in the annual report for 1917, recently published. The extra pay provision goes into effect on April 15 next; it will absorb a total extra expenditure of \$45,000,000 per annum; and will increase the wage of 200,000 employees who will then receive an average of \$3.69, compared with \$2 two years ago. About 25% of all the Corporation's employees, including practically all underground men, work on an 8-hour basis, but this provision is not to be extended to the laborers with less strenuous duties. A shortage of labor was experienced, notwithstanding the fact that the Corporation employed 15,300 more than during the previous year. The total average number of employees amounted to 268,058, absorbing a payroll amounting in the aggregate to \$347,370,400; or an average wage per day of \$4.16. Welfare work received considerable attention, and it is interesting to note that sufficient encouragement was given to employees resulting in the planting of no less than 15,765 vegetable gardens on idle land in the vicinity of the works, covering an area of 2032 acres. Provision for the inculcation of the safety-first idea and the prevention and relief of accidents accounted for over \$4,000,000 during the year.

The benefits likely to arise as a result of friendly intercourse between workers and officials has been recognized to an unusual extent by the Standard Oil Co. Regular dinners have been arranged to take place at the New York office of the company where a few workmen, selected by the vote of their fellows, will share the salt with the chairman, president, and other high officials. At the first reunion it was announced that John D. Rockefeller Sr. had donated \$50,000 of stock and \$100,000 cash for Y. M. C. A. expansion; and that a 10% increase in pay to all wage-earners, except bricklayers and watchmen, who will benefit to the extent of an additional 5% only, and lead-burners who have already received a rise, will take immediate effect. This will apply to nearly 30,000 employees. This increase makes a total increment in individual wages paid by this company recently of 98% in the case of non-skilled, and 79% in all classes. It will cost about \$3,000,000 per annum. In addition, arrangements have been made with the Equitable Life Assurance Society and all employees, without cost to themselves, will be given a life insurance policy after one year's service, which may be continued in force after the employee has left the service of the company by the payment of the annual premiums. While in the company's service all charges are met by the company. Death benefits under these policies vary with the length of service from an equivalent of three months pay to a maximum of \$2000. Annuities are to be given to employees on reaching 65 years of age and will be based on 2% of total earnings, with a minimum of \$300 per annum. Ample financial provision is to be made in the case of accidental injury. The experiment of closer personal co-operation between employer and employee has been commenced at a time when relations are particularly cordial; and it is fully expected that reunions of this kind, where anything of the nature of a grievance can be freely discussed, will tend to preserve and augment the good feeling already existing.

HOUGHTON, MICHIGAN

Decision of Supreme Court on Rights of Shareholders.

The decision of the Supreme Court of Michigan, reversing the action of the lower Court in the case of William A. Paine v. the Trimountain Mining Co., is one of vital importance not only to mining but to all corporate interests in the State. The action was a great surprise to corporation lawyers. Practically, it means that minority shareholders of operating concerns can block the dissolution of any corporation when that dissolution is wanted simply as a matter of convenience in doing business. Mr. Paine is president of the Copper Range company, which has absorbed the Champion, Baltic, and several other subsidiary companies. The basis of exchange for Trimountain shares was generally considered not only fair but more than reasonable, yet some of the shareholders would not agree. The consolidation, therefore, could not be effected without action in court, compelling the minority shareholders to surrender. This they did, with two exceptions. One of these was Senator Saulsbury of Delaware, who had been "hooked" with a large block of Trimountain share in the days of high finance. The other shareholder was Michel M. Foley, assistant county treasurer of Houghton county, Michigan. Charles Briggs, president of the Calumet & Arizona company, which had done considerable absorption of its own at one time and another, also held out as a minority shareholder in Trimountain until the case went to court. Saulsbury and Foley protested against the action in court. They were defeated, but appealed to the Supreme Court. This tribunal—the highest in Michigan—decided unanimously in their favor. The decision was written by Justice Bird and concurred by all the other justices on the bench. Quoting the decision: "It appears to be the desire that Copper Range shall be-

come the owner of all the shares instead of a portion of them. The idea back of this desire is said to be that the cost of operation can be materially reduced if the property can be operated as a unit with the Baltic and Champion. This may be commendable as a business proposition, but it is no measure of respondent's rights. The respondents made their investments when the mine was more or less of a speculation. They have been loyal and retained their investments during the years of physical development and financial vicissitudes, and now when the project has been proved to be a success they must be driven out by a forced sale of their investments for no better reason than that the larger stockholder desires to acquire it in the interest of economy."

DURANGO, COLORADO

Weather, Transport, Development, Production, and Plants in South-Western Colorado.

General.—Exceptional weather during the past winter was very favorable for mining in south-western Colorado. For a number of years there has been heavy snow and severe storms that seriously impeded shipments and development. All large producers in the principal districts continued normal shipments until January, when the Red Mountain district practically closed down for the season. The first storm that seriously interfered with railroad traffic occurred dur-

ing the past week (prior to March 18), which prevailed over the entire south-western region. The Silverton district was covered with two feet of new snow. Numerous snow-slides occurred at points on the Denver & Rio Grande between Durango and Silverton; also on the Rio Grande Southern, stopping all shipments and traffic for a week. If favorable weather continues, movement of ore from mines to smelters will be about normal in a week. At points on the Silverton branch, snow-slides cover the tracks to a depth of 50 ft.; and on Cumbres pass, where the narrow-gauge crosses the Continental Divide in order to connect with the main line, the snow is 17 ft. deep.

Durango.—The Durango smelter has been extensively remodeled during the winter, and is prepared to receive the large tonnages expected during the forthcoming season. A large Dwight-Lloyd sintering-machine was erected in quick time, and is in operation. It has increased the smelter's capacity considerably. A new Cottrell precipitating plant is nearing completion. An experimental flotation plant has been giving good results. Temperature of the flotation water has been increased and speed of the impellers has been raised. The plant is producing zinc concentrate.

A new power-line has been constructed to the San Juan coal mines. This will make the property as safe as possible although it already has a creditable record. The San Juan coke-ovens are to be increased.

Silverton.—Until the recent blockade, this district has been maintaining steady shipments of ore, and had a pros-

A New York company, known as the Minnehaha Mining & Milling Co., has been formed to operate the Minnehaha claim. This claim has never been worked to any extent.

shipping about 2000 tons per month. Flotation concentrate has increased greatly, in fact, most of the shipments are of this material. The output of iron concentrate has not diminished.

The Tomboy has been shipping 1500 tons per month, principally iron concentrate.

Lack of cars, snow, and mud-slides along the Rio Grande Southern have hampered shipping from these properties.

The Liberty Bell has been shipping 300 tons per month, and will gradually increase the quantity as the season advances.

Ophir.—The Carbonero Leasing Co. has been developing and shipped a few cars of ore. It is probable that this mine will be one of the important producers during the current year, as it is backed by a strong company.

The Carribeau Trust Co. is operating a mine in the Ophir district. The manager reports good results by flotation. Several cars of ore have been shipped, high in copper. There are large bodies of good ore undeveloped.

Ouray.—Shipping from this district is at a standstill. The Wedge and Pony Express properties show some activity, and have shipped a few cars since the first of the year. High freight-rates, coupled with a run of lower-grade ore, have temporarily brought operations to a close. Carney and Kelliher worked on the Wedge dumps and shipped some good silver ore. The Black Girl has not shipped so far. The Senorita mine closed down early in January. Among recent shippers are the Silver Point, operated by The Miners' & Merchants' Bank of Ouray, and the McCluskey's Cliff mine.

The mines of this district have always been good producers, and should ship considerable ore during the coming season. The price of silver will govern production, as all ores carry silver, and are suitable for smelting.

PLATTEVILLE, WISCONSIN

Principal New Work Under Way in Main Districts.

Spring weather has revived mining in the zinc-lead region, and many schemes set back by winter are to be resumed.

Benton.—The Frontier Mining Co. of Indianapolis, Indiana, is launching extensive development on land north and east of here proved by drills. On the Grotkin land, where the Bull Moose and Middle mines are now producing extensively, another large ore deposit is being opened. This will be connected by underground tramways with the main mill at the Bull Moose mine. This company will also develop and equip the Little Minnie mine, closed since 1907.

Local mining men, backed by Milwaukee capital, are completing a 300-ton concentrating plant at the Blende mine. Twenty years ago, by primitive methods, this property paid the owner, on 10% royalty, over \$60,000. Records show that blende of high grade sold at \$8 to \$21 per ton.

The Thomas Calvert farm, on the famous Swindler Ridge, is being exploited by the Vinegar Hill Zinc Co. The tract has been drilled. A two-compartment shaft will be sunk without delay, and a 300-ton mill erected on a short-term contract.

The New Jersey Zinc Co. is busy on a property formerly known as the Little Bennie. Recent work shows that drifts were driven by former owners just over the top of the main orebody, which is several feet thick and of fair grade. The mine is being dewatered, and the new ore opened. This mine is connected with the Fox mine, a consistent producer. The New Jersey company's Hoskins mine is producing as much as 10 cars of ore per week.

The Vinegar Hill Zinc Co. is coming into undisputed possession of the Sally mine, and operations will be resumed in the near future.

The Grand View Mining Co., controlled by Indianapolis people, will also be re-opened. Some high-grade zinc car-

bonate ore is exposed in the upper levels, and is sold to the Mineral Point Zinc Company.

The Robinson, Greater, Buchan, Domestic, Strawbridge, and Longberry mining companies are all being revived. All have ore and require additional capital to make them profitable enterprises. Each is in the heart of the Benton zinc belt, and all have considerable merit.

Ore-loading facilities are being improved in this district by use of gondolas to which shippers, especially of high-grade zinc ore, have long objected. Shippers of wet concentrate, however, are taking advantage of the coal cars by putting in wooden bottoms. The car scarcity, acute all winter, is being eliminated in this way.

Cuba City.—A new 300-ton mill has been completed at the Connecting Link mine. The mine is an extension of the Dall range, and is opening large deposits of high-grade zinc ore.

The Hercules Mining Co. will build a new mill as soon as the weather permits.

The Big Eight Mining Co. is drilling the hills for extensions of the Raisbeck range, so far with indifferent results.

Hazel Green.—Knolte brothers have a promising new zinc producer on the Crawford estate.

New Diggings.—The Galenite Mining Co., recently incorporated with capital of \$20,000, has a 40-acre tract here. Two shafts only 26 ft. deep are in ore. A drill will be used to prove this.

Livingston.—The Livingston Mining Co. has been organized to develop property near the New Jersey Zinc Co.'s Coker mine.

Platteville.—The Block-House Mining Co., which sold over \$500,000 of zinc ore in 1917, is holding \$75,000 of separator blende for better markets. Extensive development is planned by the company on its new Reilly deposit.

CRIPPLE CREEK, COLORADO

Gold Output and Dividends.—Portland Mill Closed.—Lease Notes.

Gold output of the district in March totaled 32,470 tons, averaging \$9.47 per ton, making a gross value of \$875,880. Quantities treated and values were as follows: Golden Cycle (Colorado Springs), 26,700 tons, \$20 per ton; Portland (Colorado Springs), 8370 tons, \$17.50 per ton; Portland (Independence mill, Cripple Creek), 41,000 tons, \$2.02; Portland (Victor mill, Cripple Creek), 13,100 tons, and Smelters (Denver and Pueblo), 2500 tons, \$55 per ton.

Dividends paid in March were as follows: Cresson, \$122,000, and Golden Cycle, \$45,000. These companies will pay similar amounts on April 10. Dividends for the first quarter of 1918 have totaled \$591,000, as follows: Cresson, \$366,000; Golden Cycle, \$135,000; and Portland, \$90,000.

The Colorado Springs mill of the Portland company closed on March 3. This plant commenced work in June 1902, and has extracted gold worth over \$35,000,000 from Portland and custom ores.

The Forest Queen Mines Co., recently incorporated to operate the Edwin Gaylord lease at the Forest Queen mine, produced 400 tons of 1-oz. ore during March. This is the largest monthly output since the lease was issued 16 months ago.

The Cobb sub-lease on 500-ft. level of the Dante mine, Bull hill, returned \$10,000 gross last week from 4 cars of ore, according to statement made by the company's secretary. One carload assayed \$137 per ton. The mine is leased to the Big Toad Gold Mining & Milling Co. This company has engaged Thomas Kavanaugh, metallurgist, to operate the plant, formerly known as the Reid mill. Treatment of low-grade mine ore has commenced.

ARIZONA

Jerome.—United Verde Copper Co. has declared a dividend of \$7 per share, the second of like amount this year.

Green Monster company is doing development only at two points, a half-mile apart, at its Revenue and Cliff mines. At the former, a strong jasper vein is being followed by means of workings 415 ft. below the winze from the Rattlesnake adit. At the Cliff, the Gorge adit has cut two bodies of mineralized schist carrying copper pyrite. Thirty-five men are employed, working two shifts in four places. Property is fully equipped with electric hoist at shaft, pumps, compressors, etc.

Miami.—Gila county's resources are described in an interesting manner by Edward Oliver in a 31-page booklet. There is nothing new in the matter, but it is arranged attractively.

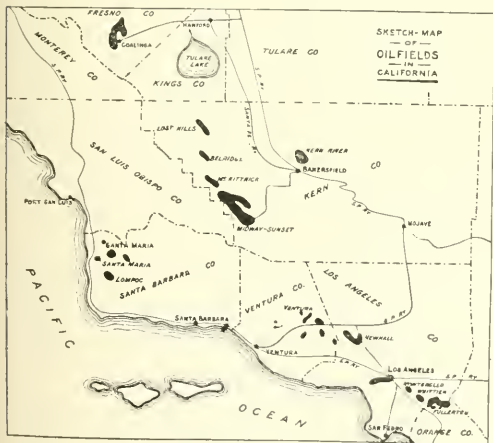

Patagonia.—Frederick Colberg, who recently acquired the Flux mine near here, is to erect a mill.

Prescott.—Storm Cloud claims in Hassayampa district are to be re-opened by the O'Brien Syndicate. No work has been done for 10 years.

Bannie Mining Co. in Walker district is installing an 80-hp. boiler, 5-drill Ingersoll-Rand compressor, etc., and will deepen shaft from 190 to 500 ft. depth. Property is considered promising.

CALIFORNIA

Drilling operations in the oilfields, as shown by reports made to the State Oil and Gas Supervisor, R. P. McLaughlin,

show a decided decline in comparison with those of a year ago. During the past week 11 new wells were started, making a total of 166 since the first of the year, an average of 14 per week. During the same period last year 270 wells were started, an average of 23 per week. Operations in the

Montebello field continue active. The use of rotary tools has been the cause of friction between various operators, based on the belief that oil-sands may be passed through without identification and proper protection. The State Mining Bureau recently held a formal hearing for the purpose of determining the facts underlying certain complaints. It developed that there is considerable uncertainty as to the existence of productive sands when rotary tools are used throughout the drilling operations. It may become necessary for the Bureau to place certain restrictions on the use of such methods. Some companies operating in the field, namely, the Amalgamated and General Petroleum, propose to use rotary tools to the limited depth of about 1200 ft. and finish the wells with cable tools. Experience in other fields has already shown this method to be far preferable where there is uncertainty as to the depth of productive sands, and similar prudence on the part of all operators may obviate the necessity for drastic regulation.

Engels.—U. S. Bureau of Mines rescue-car No. 1, with J. J. Forbes, Dr. J. F. Worley, J. V. Berry, T. M. Genty, W. W. Weir, H. M. Wolfkin, and J. H. Kisse, was at the Engels copper mine part of last week.

In 'Economic Geology' for March, L. C. Graton and D. H. McLaughlin give further notes on ore of the Engels copper mine. This and the previous investigation concerned secondary enrichment of the ore. Mr. Graton considers that the chalcocite is of secondary origin.

Gazelle.—W. L. Brown has made an initial shipment of two carloads of high-grade chrome ore mined on his ranch.

Grass Valley.—Golden Center company has opened two feet of \$20 ore on 500-ft. level, 600 ft. from main shaft.

Hornbrook.—James Ladd of Gottsville has shipped from Hornbrook an initial shipment of 42% chrome ore from his Snowflake mine.

Keswick.—Mountain Copper Co., which is doubling capacity of its flotation plant at Minnesota station, is greatly hampered in construction by the inability to get material.

Kennett.—Only 120 men are employed at the Mammoth mine, where a year ago the number was 700. The Mammoth company is working outside properties—the Shasta King and Stowell mines—and is receiving large quantities of ore from the Balaklala and the Bully Hill, so it is not necessary to work the Mammoth mine to capacity to keep the smelter running.

Oroville.—California National company is to erect a 1500-ton mill near here to treat the low-grade gold ore being developed. The deposit is wide and averages \$2.50 per ton. Ball-mills are to be used.

Butterfly mine in Morris ravine is to be re-opened. It was formerly worked as a lode mine, but a gravel deposit was found by the last owners. It is proposed to extend the adit and develop the channel. W. T. Baldwin, R. S. Kitrick, and C. F. Belding are interested.

Local people are forming a company to prospect ground in the Cherokee district where two diamonds of good quality were found recently. Prospectors assert a true kimberlite formation has been found.

Portola.—Walker Mining Co.'s property is improving all the time. The mill is dressing 100 tons of 4 to 6% copper ore daily, yielding concentrate carrying 20 to 22% copper and \$8 to \$9 gold and silver per ton. Recovery is from 95 to 97%. Ore-reserves are said to be sufficient for a much larger plant. New shaft is down 476 ft., where a station is being cut. Hoist is motor driven. Orebody has been proved on strike for over 1000 ft., of good width.

Washington.—Columbia Con. has 20 stamps dropping, and 25 men employed. Sufficient ore is exposed to keep the plant running for several months. Prospecting new ground is proceeding. E. C. Klinker is superintendent.

COLORADO

Boulder.—Tungsten Products Co. has been organized with capital of \$2,500,000, to develop the Lucky Two and other mines at Boulder Falls. About \$200,000 will be spent.

Mojave Tungsten Co. will probably resume operations at its mine and mill in near future.

Grim mine at Boulder has been taken over by Kansas City people. Sampling works and other plant are to be erected. New company is styled the Boulder Canon Tungsten Company.

Creede.—Champion Mining Co. has decided to re-open its Campbell Mountain silver mine as soon as financial arrangements are complete.

Cripple Creek.—Portland company closed its Colorado Springs mill on April 1. Such a course was intimated in the report for 1917. High-grade ore will now be treated at the Independence mill at Cripple Creek. Some machinery will be transferred, meanwhile this ore goes to the Golden Cycle plant at Colorado City. At Portland mine all sections down to 1700-ft. level have been mapped out for leasing.

De Beque.—American Oil Shale Co., operating in a canyon 7½ miles from here, is erecting a 150-ton distilling plant. Shale in this region contains 66 gal. of oil per ton.

Golden.—In the Colorado School of Mines 'Quarterly', April 1918, Victor C. Alderson contributes 30 pages entitled 'The Nature, Origin, and Distribution of Oil-Shale'. The Scotch shale industry is described, and briefly other foreign deposits. The remainder of the article considers the situation in Colorado. All interested should secure a copy of this article.

Montrose.—Sampling-works to handle radium-bearing and other ores of the San Juan region are to be erected here.

Ophir.—Carribeau Trnst Co. is about to start shipments to the Durango smelter. The manager, George L. Bingham, has improved the flotation process considerably. A high-grade copper concentrate is made.

Ouray.—Mining men have their attention centred on the Cow Creek section of this district, where molybdenite was discovered by a prospector at the beginning of winter. This area has long been regarded as worth exploration, but its inaccessibility has been a handicap. It is considered to be one of the wildest portions of the remote mountains of the Rockies. At various times there have been discoveries by hardy prospectors, who uncovered placer deposits that were soon exhausted, but no large orebody has been found. In addition to minerals, prospectors report indications of large coal and oil-shale deposits in this district.

The Indiana mines will be operated by A. B. Eisman, who has taken a lease of the property during 1918. Electric power will be used to operate drills.

The new Crawford mill at Ironton is nearly completed, and will be in operation at the beginning of the season.

The Mountain Top company has been shipping a rich silver ore, one carload being reported as bringing a net re-

turn of \$5000. A vein carrying 300 oz. silver has been opened in places. Recent profits from the mine have resulted in many improvements, among which are a long tram to facilitate handling of ore from the Mountain Top to the basin below. A large ball-mill has been erected.

Silverton.—Plans have been made for extending the 2000-ft. Mammoth adit through Red mountain. With laterals, this tunnel will serve many properties.

Telluride.—The road to the Tombay was blocked by snow for a week but is now open to sleigh travel.

Auto-trucks are again hauling ore from Placerville, after a lay-off for a month, on account of muddy conditions of roads. Roads of the district are reported to be in good condition now, as there has been a long period of drying weather.

Oil-shale lands of the district are being developed by Mt. Blaine Oil Shale Products Co., which has installed a 100-ton reduction plant near the town of Norwood.

The Belmont-Wagner mines are operating.

The Caruthers lease is shipping large quantities of ore to Perino mill. A large Huntington mill has been installed and as soon as electric power is available the season's run will be started.

There are large deposits of manganese ore in La Sal mountains, and in view of the prevailing demand for the mineral, it is possible that capital may develop this rich district.

IDAHO

Fatalities in mines of this State during 1917 totaled 21. There were 204 injured, losing more than 14 days time each, and 650 losing under 14 days.

Kellogg.—At least 1000 additional men are needed by mines and works in the Coeur d'Alene region, according to H. R. McBride, employment agent of the Coeur d'Alene Mine Owners Association at Kellogg. The companies have been advertising without success, and the situation is now acute. The chief companies affected are the big producers, and a reduction in output is threatened unless relief comes soon. Wages vary from \$3.75 to \$5.25 per day.

MICHIGAN

Houghton.—Mayflower-Old Colony company levied an assessment of 50c. per share on April 8.

Iron Mountain.—Amasa Porter iron mine is being unwatered to recover the bodies of 14 miners entombed there February 21. It will require at least six weeks to remove sand and water before operations can be resumed.

Pewabic iron mine will stop operations in the near future. Recent openings have been in poor ore, grade gradually getting worse and no hope for improvement in future. Twenty years ago Pewabic was one of the big operating iron mines of Iron Mountain district.

MISSOURI

Joplin.—Production of Missouri-Kansas-Oklahoma region last week was 8778 tons blende and 1465 tons lead, averaging \$47 and \$85 per ton. Total valuation was \$541,797, making \$6,292,105 for 13 weeks. Oklahoma contributed \$233,940 of last week's output. Zinc-ore prices fell off \$2.50 per ton.

MONTANA

Butte.—Anaconda pays \$2 per share on May 27. This makes \$4 for the current year.

Regarding the Elm Orlu v. Butte & Superior apex dispute, D. C. Jackling stated to the 'Boston News Bureau' as follows: The Elm Orlu decision, recently affirmed by the U. S. Circuit Court of Appeals at San Francisco, involves a length of about 300 ft. of the so-called Rainbow lode development in the west end of the Black Rock claim of the

The U. S. Circuit Court of Appeals at San Francisco has denied the Butte & Superior company's petition for a rehearing of the appeal from Judge B. Bourquin's decision in favor of the Elm Orlu in a suit involving orebodies in the Rainbow fissure beneath the surface of the Black Rock claim of the Butte & Superior company.

Rimini.—At Lee Mountain mine a large body of silver-lead ore was recently opened at distance of 1000 ft. from portal of adit. Vein is 7 ft. wide. About 25 men are employed. This mine has been worked intermittently for 25 years. Morton Webber is consulting engineer.

Mill City.—Tungsten shipments from this district amount to 150 tons daily. This quantity will be increased when present work opens the mines properly. About 100 men are employed. From Mill City the ore is railed to Toulon, near

one-sixth of the total length developed in the Butte & Superior properties from all parts of which system above present working-levels profitable ore has been or is now being mined. The size of orebodies and their grades vary on different levels throughout the length of the entire system, and it is impossible to say definitely what relative value the 300 ft. involved in the decision would bear to the remaining 1500 ft. of developed orebodies not so involved. If for purposes of illustration, it is assumed that the developed system of veins is of equal value throughout their present developed length, then the decision involves one-sixth of the orebodies developed through the Butte & Superior workings. It should be stated, however, that to present depths the orebodies decreed to the Elm Orlu are somewhat larger than the average of the orebodies throughout their full length developed in the property, and it is believed a fair statement of the situation would be that the orebodies lost to the Butte & Superior Co. by this decision approximate but do not exceed one-fifth of the profitable developments to depths at which we are now working. This, of course, constitutes a very important and valuable block of ore, but it is in no wise vital to the Butte & Superior or its operations now, or for an indeterminate, but very long time in the near future. As to the monetary value involved in the decision, the lower Court found that the ores taken by the Butte & Superior in violation of plaintiff's rights justified an award of damages plus interest in the total sum of \$177,707.40. There was another branch of the case which was not wholly determined by the Court. This involved claims on the part of the Elm Orlu that it was entitled to a further extension eastward of the orebodies developed in the Black Rock by virtue of apex-rights through what is known as the Pyle Strand, which plaintiffs claim is an easterly extending branch of the Rainbow lode. To what extent this may affect further por-

Lovelock, for concentration. Scheelite occurs in veins that are persistent with depth. At the Uncle Sam an adit has been driven on a vein for 300 ft., the face being 176 ft. deep. Vein is 6 ft. wide, and 4500 tons averaged 2.11% WO₃. Lessees are shipping 3½% ore. L. A. Friedman has a shaft down 85 ft. on a 6-ft. vein. Ore carries 2% tungstic acid. It is proposed to erect a custom mill here.

Virginia City.—Concerning operations on the Comstock, Whitman Symmes states that results of many months work are becoming apparent, notably in the case of Union Consolidated, which is maintaining its production without aid from high-grade ore. Ore is being opened as fast as it is taken out. There are two cross-cuts, one on 2400 and the other on 2600-ft. level, which will tend to prove further the size of the orebody, which centres in workings at 2460 ft. As opportunity permits, encouraging indications on the 1600, 2000, 2700, and 2900-ft. levels are to be followed. Cross-cuts on 2400 and 2600-ft. levels are not yet far enough advanced to reach the ore, but at 2500 ft. a drift for 73 ft. was in good ore. At 2300 ft. there is good ore in the south drift, considerably to the east of the 2400-ft. level ore-shoot. The ore went only to the top of the drift, but was solid on the floor, with 7 to 8 ft. of quartz. This should be cross-cut at 2400 ft. From 2460 to the 2400-ft. level, stoping has been done only at the north end. There is a fair amount of ore remaining between the 2400 and 2300-ft. levels. From 2500 to 2460 ft. is untouched, and this will supply milling ore for a considerable period.

Mexican mill here is to be enlarged to take care of the steadily increasing output of the Comstock Lode mines, particularly the Union Con., Con. Virginia, and other North End properties. The plant is taxed to capacity to treat ore coming from the Union Con., Ophir, Mexican, and Con. Virginia.

Reported by United Comstock Pumping Association that operations last week consisted of the following: At C. & C. shaft the Reider pumps on 200-ft. level ran as follows: No. 1, 72 hours; No. 2, 143½ hours; No. 3, 120½ hours. The centrifugal pumps at 2310-ft. station ran: No. 2, 168 hours; No. 3, 168 hours. No. 2 shaft-pump at 250-ft. station ran 168 hours. The pumps on 2700-ft. level ran: No. 3, 109½ hours; No. 4, 58½ hours. Pumps on 2900-ft. level ran: No. 1, 120 hours; No. 2, 48 hours. On 1600-ft. level main south drift from the Union shaft leading to the north lateral of Suro tunnel is being repaired. This drift is used to turn the drainage-water, and is one of the main outlets for the northern mines. At Ophir shaft general repairs to shaft were made.

OKLAHOMA

Douthat.—Forty-acre lease of C. H. Plumb and Edward Wilkins of Joplin has been sold for \$50,000 to E. R. McClelland of Kansas City. The St. Regis mill at Duenweg, Mo., is to be moved to Douthat.

Lincolnville.—This old district is again assuming importance. Considerable drilling is being done, and 10 mills are completed or under construction.

Miami.—Miami National Lead & Zinc Co. will soon have two mills in operation, one of 200 tons capacity at Badger, the other of 150 tons at Peacock. Rich ore has been opened. H. C. Austin is general manager.

Picher.—Production of this region last week was 3782 tons blende and 750 tons lead, valued at \$233,940.

OREGON

Homestead.—The Iron Dyke copper mine here, in northern Oregon, near the Idaho line, is said to have ore worth \$1,000,000 opened above 300-ft. level. Monthly profits to people connected with the Goodrich Rubber Co. are reported as \$75,000 to \$95,000. A wide orebody, carrying 3 to 5% copper and \$8 to \$10 gold per ton, has been developed.

TEXAS

Rule.—Texas Development & Mining Co., with headquarters at Nacogdoches, will build a smelter at its copper mines near here.

Terlingua.—Mariposa Mining Co. has leased the 50-ton Scott quicksilver furnace belonging to the Terlingua Mining Co. in this district of Brewster county, and will put it in operation as soon as it can be overhauled, which will require from 30 to 60 days. The Mariposa quicksilver mine adjoins the Terlingua mine. It is equipped with two 10-ton Scott furnaces, having a capacity of 100 flasks of quicksilver per month. The Terlingua furnace will be supplied with low-grade ore from the Mariposa, of which there is 32,000 tons on dumps, containing, according to report of the engineer, more than \$241,000 of mercury. Some high-grade ore will be added to the dump material, and according to report of William B. Phillips, consulting engineer, the expected output of quicksilver will be from 250 to 300 flasks per month. F. M. Dancy is president.

UTAH

American Fork.—Pacific Mining Co. paid 1c. per share on April 5. This is No. 3, equal to \$4000.

Bog Mining Co. has resumed work, and is extending its adit 100 feet.

Bingham.—Alleging that the United States Mining Company had extended adits and workings into his property, known as the Nemesis lode, and had extracted ores therefrom fraudulently, Colonel E. A. Wall filed suit for \$16,875,000 damages against the company in the Federal Court at Salt Lake City on April 4.

Garfield.—Utah Copper Co. may have labor troubles, as last week a meeting of those involved voted 84 for and 9 against a strike, in order to obtain guarantees against discrimination of union men employed by the company. Union men are said not to be receiving fair treatment when numbers of employees were being discharged. The general manager, R. R. Gemmell, says that the company continues to operate on the open-shop system, not asking any man whether or not he carries a union card; it is entirely a matter of efficiency. There are at present employed approximately 3500 men at the two concentrating plants at Magna and Arthur. Mr. Gemmell said that the reported vote of 84 men favoring a strike would represent a small and unimportant part of the total number employed at the two plants. However, it is the general expectation that the matter may be settled in an amicable manner.

Park City.—Mines of this district in March shipped 11,109 tons of ore and concentrate, against 9222 tons in February. Producers were as follows: Ontario, 3190; Judge, 2615; Silver King Coalition, 2717; Silver King Con., 1153; Daly West, 1094; Iowa, 132; Naildriver, 155; and New Quincy, 53 tons. Value for three months of 1918 is \$1,500,000.

Tintic.—Mines of this district in March shipped 41,000 tons of ore and concentrate. There are 24 producers in the list, headed by the Dragon, Chief Con., Iron Blossom, Mammoth, Grand Central, Eagle & Blue Bell, and Centennial, Eureka.

WASHINGTON

Republic.—Lone Pine-Surprise company, operating Last Chance mine, has sunk its shaft 530 ft. At 500 ft. shaft cut the vein, where it is 8 ft. wide. A station 11 ft. wide, 15 ft. high, and 15 ft. long was cut out, partly in ore. A loading-pocket of similar dimensions was cut below the level. Drifts each way—198 and 86 ft.—were in ore all the way. Average width is 8 ft. Shoot has yielded over 6000 tons of ore, assaying \$12.50 per ton. Just south of the shoot the

vein is split into stringers a few inches to 30 in. wide, averaging \$7.50 per ton. Metal content is 66% gold and 33% silver. Ore is shipped to smelters. The mine is in fine physical condition. C. P. Robbins is manager.

CANADA

British Columbia

Dividends paid by companies operating in this Province are as follows for the first quarter of 1918, compared with the previous period:

	Last quarter 1917	First quarter 1918
Granby Con.	\$374,962	\$374,962
Consolidated Mining & Smelting....	260,445	261,935
Hedley Gold	60,000	36,000
Standard Silver-Lead	100,000
Total	\$795,407	\$672,897

Princeton.—Canada Copper Corporation has completed its 2900-ft. tunnel through Copper mountain. The opening is 9 by 11 ft., and will facilitate removal of over 10,000,000 tons of ore in the upper horizons. A vertical raise 720 ft. high will be driven from the tunnel. Surveys for mill-site are under way. Oscar Lachmund is general manager.

The Kettle Valley railroad has let contract for the construction of 14 miles of line from Princeton to Copper Mountain, to serve the Canada Copper company's property. Amount involved is said to be over \$1,000,000.

MEXICO

A Consular Report of March 27 states that the American Ambassador at Mexico City has telegraphed the following decree of March 22, concerning the exportation of gold and silver, which modifies the decree on the same subject of September 27, 1917, referred to in 'Commerce Reports' of October 1, 1917:

Article 1. The exportation of silver bars and of bars of gold and silver mixed may be made only with the special permission of the Secretary of the Treasury and Public Credit in each case.

Art. 2. For the exportation of ores and concentrates containing gold and silver the provisions of the decree of September 27, 1917, shall continue in effect.

Art. 3. The absolute prohibition of the exportation of gold bars of domestic production and of domestic and foreign gold coins and domestic silver coin continues in effect.

Art. 4. Subject to arrangements to be made in each case with the Treasury Department, the exportation of silver coin (pesos fuertes) may be permitted on condition that gold bullion equivalent in commercial value to the coin is imported at the same time for coinage at the mint.

Art. 5. The monetary commission, with the approval of the Treasury Department, shall obtain the gold and silver bars it may consider proper for storage or coinage at the mint.

Art. 6. The importation of domestic or foreign gold in bars or coin is exempt from the payment of consular fees and consular invoice charges.

Another telegram from the American Ambassador, dated March 21, states that, according to an announcement appearing in the press, the Treasury Department has given instructions to all customs-houses and tax-collecting officials in Mexico not to receive paper currency of the United States in payment of duties or taxes. (A similar order directing that American paper, or silver, or bills of exchange on the United States should not be accepted in payment of Federal duties and taxes, was issued in September 1917, and was also referred to in 'Commerce Reports' of October 1, 1917).

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

E. L. Dufourey is in Mexico.

H. Foster Bain is at Washington.

James M. Hyde has gone to Washington.

J. P. Graves, of Spokane, is at the Fairmont hotel.

Donald M. Palmer is with the Chino Copper Co., in New Mexico.

A. H. Higgins, of Minerals Separation Ltd., has gone to Arizona.

C. Gore-Langton is with the Du Pont Nitrate Co. at Iquique, Chile.

Augustus Locke has returned to San Francisco from Durango, Mexico.

Chester F. Lee was in San Francisco for a few days on his return from Nevada to Seattle.

Carlos Billick is in the Ordnance Department, U. S. N. A., stationed at Alturas, California.

W. L. Williamson has been made superintendent of the Allison Ranch mine at Grass Valley.

Jackson A. Pearce, formerly at Idaho Springs, Colorado, is now residing at Berkeley, California.

Robert W. Jones has been appointed inspector of mines and tunnels for the State of New York.

D. C. Bard, consulting engineer to the Ladysmith Copper Corporation, has returned from Alaska.

Henry E. Wood passed through San Francisco on his return from southern California to Denver.

A. G. Wolf has been appointed superintendent of the Mary Murphy mine at Romley, Colorado.

N. M. Muir is engaged on work relating to the recovery of gasoline contained in natural gas in Oklahoma.

Guy C. Riddell has returned from Australia and is now metallurgical expert to the U. S. Tariff Commission.

H. O. Hammond has been appointed chief chemist for the United Verde Extension Mines Co., at Jerome, Arizona.

J. W. Hutchinson, general manager for the Goldfield Consolidated Mines, has resigned in order to engage in patriotic service.

Richard Roelofs has resigned as superintendent for the Cresson Consolidated at Cripple Creek and is now at Los Angeles.

A. R. Globe, formerly at Kimberley, South Africa, has been appointed assistant general manager of the Hollinger Consolidated at Porcupine.

J. O. Greenan, superintendent of the Olympic mine, in Nevada, has volunteered for service with the 27th Engineers and has gone to Fort Douglas, Utah.

R. H. Stewart has entered into partnership with A. G. Larson and Arthur Lakes, as consulting mining engineers, with offices at Vancouver and Spokane.

W. W. Mein has been placed in charge of the fertilizer branch of the U. S. Department of Agriculture, as "immediate representative" of the Secretary of Agriculture.

B Barclay Benthorne, representing Lewis & Marks, Lord D'Abernon, and other British capitalists interested in mines in British Columbia and Mexico, was killed in a motor-accident at Oakland, California, on March 27.

Rudolf Gahl has resigned as metallurgist to the Inspiration Consolidated Copper Co. and is succeeded by Guy H. Ruggles, lately mill-superintendent for the Consolidated Arizona Smelting Co. at Humboldt, Arizona. Dr. Gahl will engage in consulting work, continuing to reside in the Globe-Miami district.

THE METAL MARKET

METAL PRICES

San Francisco, April 9

Aluminum-dust (100-lb. lots), cents per pound.....	70
Aluminum-dust (ton lots), cents per pound.....	65
Antimony, cents per pound.....	15 1/2
Antimony (wholesale) cents per pound.....	13 1/4
Copper, electrolytic, cents per pound, in carload lots.....	23 1/2
Copper, electrolytic, cents per pound, in small quantities.....	24 1/2
Lead, pig, cents per pound.....	7 1/2 — 8 1/2
Nickel, cents per pound.....	55
Platinum, pure and with 10% iridium, per ounce.....	\$108—\$114
Quicksilver, per flask of 75 lb.....	\$115
Spelter, cents per pound.....	10
Zinc-dust, cents per pound.....	17 1/2

Antimony smelting in China, which country supplies 60% of the world's output of this metal, is fully described by Chung Yu Wang in a paper prepared for the Colorado meeting of the A. I. M. E. The antimony industry of China started in 1897.

Bumuth in England is now under Government control, only certain quantities being allowed dealers and manufacturers.

Nickel prices—as arranged by the Government and the International Nickel Co.—have been fixed at 40c. per lb. for the best grade and 38c. for the lower grade.

ORE PRICES

San Francisco, April 9

Antimony, 45% metal, per unit.....	\$1.10
Chrome, 38% and over, f.o.b. Cal., per unit.....	\$1.25
Magnesian, crude, per ton.....	\$8.00—10.00
Manganese, 40%, at Heroult, Cal., cents per unit (long ton).....	75
Manganese, chemical, per ton.....	\$80—100
Tungsten, 60% WO ₃ , per unit.....	\$20—24
Molybdenite, per lb., 85% MoS ₂ (nominal).....	\$1.80
Pyrites, domestic, per unit of sulphur, cents.....	28

The magnesian market is practically dead.

Manganese imports are declining. In January there was 42,947 tons landed, against 49,530 tons a year ago; and in 7 months ended January 31, 1918, a total of 356,129 tons, compared with 388,828 tons in the previous period.

The possible treatment of manganese ores in California is thoroughly discussed by E. A. Hersam in Vol. 2, No. 1, pages 1 to 56, of the University of California publications. There appears abundant reason why these low-grade deposits should be developed. Manganese producers should study this investigation.

EASTERN METAL MARKET

(By wire from New York)

April 9.—Copper is quiet. Lead is inactive, though steady. Spelter is quiet and lower.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver. For San Francisco prices add 3 cents per ounce.

Copper refineries and mining companies have, in a number of cases, re-adjusted contracts. Prior to the War, contracts were based on prices ranging from \$14 to \$17 per ton. Old contracts have been renewed at \$25, and new contracts at \$35 per ton.

Brass exports from United States in 1917 were valued at \$239,857,967, a decrease of \$75,798,790 compared with the previous year. Common brass contains 64% copper.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date	1916	1917	1918	Date	1916	1917	1918

It is reported that the Government has issued an order to quicksilver producers to hold, subject to its requirements, a tentative 40% of their total output, the exact amount to be decided later.

Mercury consumed at the six mills of the Homestake company, South Dakota, in 1917, cost \$41,700, which, at the average of about \$106 per flask last year, equalled nearly 400 flasks.

TIN

Prices in New York, in cents per pound.

Date	1916	1917	1918	Date	1916	1917	1918
Jan.....	41.76	44.10	85.13	July.....	38.37	62.60

Spot tin is scarce. No Straits or Banka metal is available in open market, only Bolivian and Chinese. In domestic trade dealers quote from 88 to 93c. If Straits were procurable it would be \$1 per lb. National Lead Co. has completed a tin smelter at Jamaica Bay, Long Island, N. Y. Company is connected with Williams, Harvey & Co. of England. Ore will come from Bolivia.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Zinc-ore prices at Joplin, Missouri, dropped \$2.50 per ton last week. Business was done at \$60, \$47.50, \$45, and \$40 per ton for four grades. Calamine sold at \$30 to \$35 per ton, basis 40% metal.

Eastern Metal Market

New York, April 3.

Inactivity is generally characteristic of all markets; in some an easier tendency has developed into weakness.

There has been no change in any department of the copper market.

Tin transactions are restricted, despite a good demand.

Lead is much less active than for some time, and is lower.

Zinc has developed decided weakness, and is lower.

Antimony has declined on small dealings.

The feature of the iron and steel market is the remarkable recovery made in pig-iron output in March over January and February. The total was 3,213,991 gross tons, or 103,648 tons per day, against 2,319,399 tons in the 28 days of February, or 82,835 tons per day. Coke supply has increased, enabling more furnaces to operate, the month's net gain having been 24. The 344 coke iron furnaces in blast on April 1 were producing at the rate of 106,500 tons per day, which compares with the 1917 average of 105,000 tons per day. Three new modern blast-furnaces were blown-in last month. Government needs figure so largely in steel consumption that ordinary consumption has become incidental. A total of 1,000,000 tons of plates and 250,000 tons of shapes is estimated as needed to produce the pending 100,000 steel cars. The designing of standard freight-cars means that a good many patented car specialties will be omitted, disturbing some makers. Government rail requirements will add 300,000 tons, or more than 10% to the total that the railroads have already ordered for 1918.

COPPER

In the absence of any price changes or speculation, news is at times also a scarcity—more so this week than for some time. The market has subsided to one of regulated procedure as to price and material. It is a question almost entirely of supply and demand. These are now generally regarded as about balanced, with production fast approaching a rate of 200,000,000 lb. per month. Labor is the only retarding influence, and the new draft may accentuate it. Deliveries of raw metal to Eastern refineries are reported as much more satisfactory, which of course promotes output. Consumption is tremendous for international war purposes here and abroad. Domestic consumption for non-essentials is not large, as most copper-consuming industries are directly or indirectly engaged in war work. Exports continue on a large scale, those for March being estimated at 40,000 gross tons, a little larger than those in February. The Government prices of 23.50c. per lb. for carload lots and larger, and of 24.67c. for less, are in force until June 1. As to a revision for higher prices, less is heard, with opinion divided as to the justice or any probability of such.

TIN

Considerable interest is shown here as to the effect of the seizure of Dutch vessels on receipts of Banca and Dutch tin in American ports. Indications are that the Netherlands government will use this as a club to exact certain concessions from the United States. Dutch tin imports constitute an important proportion of our supplies, and any loss of these would intensify an already critical situation. The market as a whole is unchanged from last week. There are numerous buyers of future metal, but sellers are few. The scarcity of those willing to sell is still as pronounced as a week ago, when it was emphasized in our letter. It is hard for buyers to obtain supplies, but if the metal were offered in quantity it could be sold without trouble. Spot metal is

unobtainable, but is regarded as nominal at 85c., New York. Last week a moderate business was reported, consisting largely of May-June shipment from the Far East. Cables continue greatly delayed which, together with the scarcity of sellers, accounts for the light trading. Arrivals in March totaled 1700 tons, and the estimated quantity afloat is about 6300 tons. Stocks in store and landing on March 31 were only 134 tons, indicating how low spot metal actually has declined. The first of each month used to show 2000 to 2500 tons. The London market is unchanged since a week ago when spot Straits was quoted at £317 10s.

LEAD

In New York and the East the market has been and is very quiet. It is also slightly easier, with quotations a little lower than a week ago, or 7.15 to 7.20c., New York, and 7c., St. Louis. Very little business is reported. In the West the situation is a little different. Some reports are to the effect that lead has been offered and sold at 7c., but it is believed that the volume was not large. The entire market is a drifting easy one. The A. S. & R. Co. is still quoting 7.25c., New York, but some believe a reduction in the near future not unlikely.

ZINC

The market has continued to sag on offerings from certain sources, and quotations are lower than for many months. Yesterday prime Western for April delivery was quoted and sold at 7c., St. Louis, or 7.25, New York. It is understood that sales have been made at this level for even May and June delivery. In either case the amount involved has not been large, though some 100-ton lots have changed hands. The cause of the weakness is probably due to the keen desire of a few interests to obtain cash. It is also suggested that it may result in some smelters suspending operations. For many, if not the majority, it is claimed there is a loss at present prices. The net result is expected to be a curtailment in output and not a large stimulus to consumption. Until the supply is less than the demand, or at least not greatly in excess, as at present, a firmer market is not expected. Grade A continues in large demand by the Government, which has a fixed price of 12c. per pound.

Sheet zinc is officially pegged at 15c., base.

ANTIMONY

The market is lower at 13c., New York, duty paid, for Chinese and Japanese grades, with sales of small consequence and demand light. Antimony imports in January, according to statistics just issued, were low, or 1,186,361 lb. compared with 2,036,029 lb. a year ago. This covers regulus and metal in ore and matte. Imports were only one-third of the average of the last six months of 1917.

ORES

Molybdenum: The market is inactive at unchanged prices. Prospective foreign orders for ferro-molybdenum may enliven the situation.

Tungsten: Activity has pervaded the market during the last week, and concentrates have sold at \$20 to \$24.50 per unit, basis 60% WO₃, depending on quality and delivery. High-grade wolframite has brought \$24, and scheelite, \$24.50. Embargoes are still retarding shipments. Ferro-tungsten is obtainable at \$2.25 to \$2.40 per pound of contained tungsten. The demand for tool-steel is sure to be greatly increased, due to nearly \$30,000,000 of ordnance and machine-tools to be made.

Company Reports

IRON CAP COPPER CO.

Property: mine at Globe, Arizona, adjoining Arizona Commercial and Old Dominion.

Operating Official: F. A. Woodward, superintendent.

Financial Statement: surplus on January 1, 1918, was \$287,502.

Development: the Williams shaft was sunk 128 ft. to depth of 1083 ft. The Iron Cap shaft was sunk to 15 ft. below No. 10 level, where a cross-cut passed through the vein in January 1918, showing good bornite ore. On 800-ft. level, drifts have opened the vein for 600 ft., mostly commercial. Stopes for 406 ft. are 10 ft. wide. On No. 9 level stopes are out 372 ft. These two levels are supplying over 200 tons of ore daily. No. 7 shows little ore.

Production: 20,989 tons of ore to El Paso smelter and 10,631 tons to Old Dominion mill yielded 4,584,000 lb. copper and 145,788 oz. silver.

WELLINGTON MINES CO.

Property: zinc mine and mill in Breckenridge district, Colorado.

Operating Officials: R. M. Henderson, general manager; C. Charpiot, secretary.

Financial Statement: receipts from all sources in year ended November 30, 1917, totaled \$1,102,107, of which \$1,069,969 was from concentrate sold. Operating charges were \$464,696. Period started with balance of \$227,799, and ended with \$375,211, plus \$90,000 in Liberty Bonds.

Dividends: sum of \$400,000 was paid in 1917, making \$1,300,000 in three years.

Development: new work covered 3453 ft. Main shaft was sunk 150 ft. below No. 5 level. A 450-gal. per min. pump was installed. Great Northern vein produced all the ore.

Production: 41,900 tons of ore assaying 24.5% zinc was milled, yielding 20,420 tons of 46% concentrate; 6179 tons of 43% ore was sent direct to smelters, with 7650 tons of low-grade iron-bearing tailing.

HOLLINGER CONSOLIDATED GOLD MINES, LTD.

Property: large gold mine and mill at Porcupine, Ontario.

Financial Statement: for year ended December 31, 1917, revenue totaled \$4,271,260, of which \$4,261,939 was from gold produced. Operations cost \$2,261,711, leaving \$2,009,548, less \$289,234 for taxes, depreciation, etc. The year started with a deficit of \$269,591, which was wiped out. Plant expenditure was \$673,238. Surplus is \$712,724, consisting of cash, bonds, bullion, and debentures. Current assets and bullion exceed liabilities by \$798,293.

Dividends: \$738,000 was distributed in 1917, making \$8,194,000 to date, since 1912, including consolidated companies. Payments were suspended last year, but may be resumed soon.

Development: new openings totaled 29,696 ft., in addition to 8024 ft. of diamond-drilling. Development cost \$131,224 in 1917, making \$1,412,462 since 1910. Shortage of labor retarded progress, and present 750 miners is 66% of normal requirements. Mining cost increased from \$2.17 to \$3.51 per ton. Ore-reserves in 38 main veins and on surface are estimated at 4,494,510 tons, averaging \$8.95 per ton. Total value of \$40,231,435 is \$6,045,900 more than a year ago, although \$4,261,939 was extracted during 1917. These reserves are mostly above 800-ft. level. Work is under way at depth of 1250 feet.

Production: the 2500-ton mill treated 508,139 tons of \$8.67 ore and 6162 tons of old concentrate worth \$7.71

per ton. Extraction was 95.16%. Output to date is \$19,728,383 from 1,950,121 tons treated.

Costs: averaged \$2.959 for mining, \$1.017 for treatment, and \$0.463 for general charges, a total of \$4.439 per ton.

SAN TOY MINING CO.

Property: silver-lead mines in Santa Eulalia district, Chihuahua, Mexico; and through a subsidiary, the Lawrence Mining Co., controls the Bonney property near Lordsburg, New Mexico; also an interest in 300 acres of zinc land at Ozark, Missouri.

Financial Statement: income in 1917 totaled \$26,715, of which \$20,850 was from rentals. Expenses were \$33,292, leaving a deficit of \$6577. Balance at January 1, 1917, was \$232,639, and at December 31, 1917, \$316,062.

Development: Mexican property has been leased to the Compañía de Minerales y Metales for 10 years, on royalty of 15% on net smelter returns, minimum to be \$300,000, payable monthly in advance in instalments of \$2500. At Lordsburg No. 2 shaft was sunk to 450 ft. depth. Development on this level has been good. From upper levels, 6800 tons of ore, yielding \$9.20 per ton net from smelter, was mined. High costs left no profit, so in August production was suspended. A permanent power-plant is to be ordered. When erected, ore extraction will be resumed. At Ozark, mill repairs and development occupied the time from July to December. Prospects are considered satisfactory.

NATOMAS COMPANY OF CALIFORNIA

Property: over 15,000 acres of dredging land near Folsom and Oroville, also over 70,000 acres of farm lands in Sacramento county, California. Equipment includes 13 large modern electrically-driven dredges; two rock-crushing plants; and land-reclamation machinery.

Operating Officials: Emery Oliver, general manager.

Financial Statement: gross earnings from dredges in 1917 was \$2,303,544, of which \$1,099,309 was profit. Non-operating expenditures (bond redemptions, notes payable, sinking-fund deposits, No. 5 dredge construction, and reclamation projects) totaled \$1,204,464. Current assets are placed at \$1,165,698, and current liabilities \$185,993. After charging during 3 years \$2,741,295 for exhaustion of dredging ground and depreciation of plant, there was a deficit of \$763,527. All properties are valued at \$17,222,339. Mortgage and bonded debt stands at \$10,640,835. Total cost of reclamation work in both districts is \$4,455,000. District No. 1000 is finished. Lands sold to March 19, 1918, amount to 9391 acres, realizing \$2,727,861.

Development: reserves of gravel are estimated as 247,200,000 cubic yards. No. 1 dredge near Oroville dug old ground in 1917, making a profit of \$67,648. No. 1 and 4, near Natoma, are re-soiling the land successfully. Drainage-canals in No. 1000 district total 130 miles, and roads 116 miles.

Production: all dredges dug a total of 27,106,000 cu. yd., averaging 8.5c. per yd., at cost of 4.4c. per yard. The crushing-plants produced 435,351 tons of crushed rock 53,635 tons of washed gravel, and 157,430 tons of screened gravel.

CORDOBA COPPER CO.

Property: mines and works near Cordoba, Spain.

Operating Official: James Hocking, superintendent.

Financial Statement: in 1917 sales of copper, etc., realized £193,615. Profit was only £13,513, due to abnormal conditions.

Development: 2118 ft., against 6821 ft. in 1916. Results were disappointing. Reserves are 99,139 tons of 2.16% ore.

Production: concentrator and smelter treated 61,373 tons of ore assaying 2.77% copper, yielding 3,480,960 pounds.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

STEEL MINE-TIMBERS

Steel mine-timbering has been slow in winning public favor, but its use is steadily increasing. The earlier designs were defective in some respects, and they were not used with due regard to their limitations. The Carnegie Steel Co. has for a number of years made a specialty of steel shapes for underground use, it has just issued a seventh revised edition of an illustrated booklet on the subject, which will prove highly interesting to mine managers and foremen. The miner's objection to steel on the score of its rigidity is applicable only to stulls. It is true that no timbering can resist an extensive movement of rock-masses, and that the function of timbers is to prevent the beginning of movement. Resistance to it after it has begun to move may be effective if the mass readjust itself through fracturing and becoming keyed, and the doubling of posts and caps is done in the hope of such action taking place. In the mines at Butte enormous amounts of timber have been used with this object in view. The use of steel supports has not, to our knowledge, been successfully applied in square-sets for holding open large stopes, but in gangways the steel post and cap generally offers an advantage. When a post is broken it is useless; as soon as it begins to bend, it is crushing, and a new set must soon be placed to prevent a spill. The steel post or cap, however, can be drawn, and the open-hearth mild-steel shape admits of being straightened in the shop. It is then useful for further service as an auxiliary support, or as a stull. The steel will bend soon enough to reveal a movement before it becomes uncontrollable. In the early days steel columns for mine-work were made with the idea of rigidity sufficient to resist the actual movement. This was an error; a proper degree of flexibility is essential for safety, and the steel channels now employed are as satisfactory in that regard as timber. While still used mainly in permanent gangways, they are also in favor as stulls where the conditions favor their recovery after the ore or coal has been worked out. In some of the later adaptations of the caving method, as seen, for example, at the Miami mine in Arizona, steel sets have been found serviceable in the gangways on the drawing-off level, although these levels are progressively lost as caving proceeds. Here they seem to be more reliable than timber because they yield under the crush of the ore in time to prevent a sudden collapse, and by resisting better than timber they afford opportunity for the slower movement of the caving ore, which causes better disintegration, that is, it yields less blocky material that would choke the chutes and require block-holing. The recovery of steel set-members under these conditions is quite satisfactory. The question, of course, is one of economy; it depends primarily upon the relative. Costs of steel and timber at any particular property delivered in the mine, taking into account the cost of cutting and fitting the timbers, the extra weight, bulkiness, and difficulty of handling, as against the greater ease of transporting the steel set-members. Also, there is a difference in the cube of excava-

tion to give the needed section in the level. In the older forms of steel sets there was no flexibility in adjustment, but this is overcome by pine and wedges at the joint. Rigidity of the posts is secured by pipe-separators, and posts are placed on steel base-plates. The mine is not filled with chips and decaying wood when steel is employed; it means

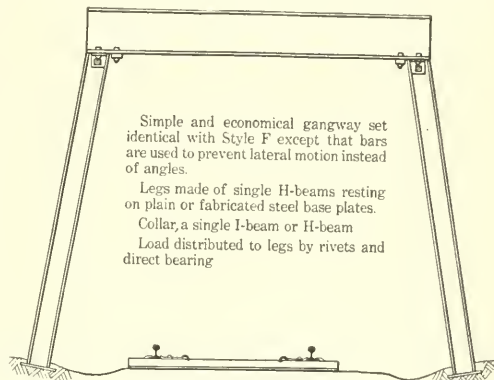

Fig. 1—Gangway Set, Style G

Fig. 2—Gangway Set, Style I

REPRESENTATIVE GANGWAY SETS WITH H-BEAM LEGS

better air, and healthier conditions; the peril of fire is eliminated, and the workmen will make a stronger effort to recover steel-sets from old workings, so that the salvage is greater.

Proper Design of Steel Mine-Timbers. The cost of a durable material may be much enhanced by improper methods in its preparation for final use. Details of framing should be simple and connections should be of minimum

weight so that the cost of fabrication may be the least possible consistent with good engineering practice. Above all, the kind of steel sections to be used should be chosen with a view to the character of stresses so as to ensure proper and most economical distribution of the loading.

Fig. 1 and 2 show designs of merit for three-piece gangway-sets. Either of these might be adequate for use under any given loading. When adjusted, however, to the same loads, the same spans and the same clear heights, their costs differ widely. Assume that it is desired to substitute steel for a three-piece double-track gangway-set made with 15-in. round yellow-pine timbers, the legs of which are 8 ft. high in clear and the collar 10 ft. long between legs, and that the steel is to carry the full load of seasoned timber: The figures given in the table show the comparison for a single-track gangway-set. Framed in steel of strength equivalent to seasoned wood timbers, the collar would be a 10-in. 25-lb. I-beam and the legs each either a single 5-in. 18.7-lb. H-beam or two 6-in. 10.5-lb. channels.

Comparative Costs of Steel Mine-Timbers
Single-track gangway-supports—10-ft. span, 6 ft. high.

Style	Figure No.	Cost per set		Weight per set		Cost per pound

D	3	765	800	17.48	18.65	2.29	2.33
E	4	605	600	11.50	13.20	1.90	2.00
C	5	565	605	9.88	11.15	1.75	1.84
F	6	569	590	10.84	11.49	1.90	1.95
G	7	566	587	10.78	11.44	1.91	1.95
I	8	600	630	11.90	13.30	1.98	2.11

The figures given in both are for material not painted. If painted, one shop-coat of the usual shop-mixture, the cost would be \$2 per net ton additional throughout. The figures in both comparisons are based on plain structural steel at \$1.60 per 100 lb. f.o.b. cars, Pittsburgh, Pennsylvania, taken as a fair normal price. The cost per set can be adjusted to any other basis by the simple addition or subtraction of the weight multiplied by the price differential. Variable conditions make it difficult to compare the cost of steel and wood mine-timbers except on the basis of specific instances. As a general rule, when consideration is had to depreciation and ultimate expenditure, the operator can afford to pay for correctly designed steel sets three to four times the cost of wood-sets of equivalent strength. In a few cases steel has even been substituted for wood at almost equal cost prices.

Comparisons should always be based on first cost, length of service, cost of renewal and maintenance and interest on total investment. Consideration should also be had to such apparently extraneous matters as ventilation, fire risk, and interruption of operation when wooden timbers come to be renewed.

Stresses in Mine-Timbers. In the use of steel for timbering, the safe guide is experience. The exact amount and exact direction of the pressures exerted by roof, walls, and floor are in many cases indeterminate. General principles only can be stated. The interpretation of these principles must rest upon experience and analogy. Where steel is to replace wood, the problem of the designer is to select from the tables the steel sections equivalent in strength to the wooden timbers which are in use and then to work out connections and other details so as to ensure a minimum cost of fabrication. If experience indicates the wood timbers to be too light, if they fail from over-strain rather than decay, the steel sections should be made somewhat heavier than required by the tables so as to cover that over-strain. The strength of an assemblage is the strength of its weakest member. In a three-piece gangway-set each leg seldom car-

ries more than half the load on the collar, and in most cases needs only to be proportioned thereto. Where this method of computation loads a leg to its full theoretical value, it is customary to use the next heavier section to provide against cross-bending due to the wedging, weight of lagging, and other indeterminate factors. In new work it is safest to use somewhat heavier sections than required by the rules.

FIG. 3—ACTUAL ROCK CLEAVAGE, INCLINED STRATA

Fig. 3 shows the common condition where the strata are inclined, where the cleavage is not symmetrical, and arch is fashioned but irregular. In this case the apex of cleavage is nearer one end of the collar than the other. The magnitude of the load is computed, as in the case of symmetrical cleavage, from the weight of the cleavage prismoid. The centre of gravity of the load must be determined and from that basis the maximum bending moment can be computed. If the apex of the cleavage prismoid is over a support, the maximum bending-moment is the same as for a beam loaded with a load increasing uniformly to the centre. The values of M_{max} will, therefore, range within these two limits; that is, from 0.1287 Wl to 0.1667 Wl , but can be computed exactly from the formula given in Fig. 4.

FIG. 4—FLEXURE FORMULA,
UNSYMMETRICAL LOADING

The loads on the two legs are not equal and in their design the more exact solution of the problem should be made and the reaction at each end of the beam computed in accordance with the formula.

Fig. 5 shows a typical five-compartment mine-shaft framed exclusively in steel, and lagged with wooden plank, concrete slabs, or corrugated iron. The shaft-sets are made of H-beams and the stuttlers are made of angles whose use secures stiffness, while at the same time it dispenses with the hanging-rods necessary in the installation of wooden sets. With this type of construction the load is distributed equally on the bearers above and below. The advantage of the H-beam wall-plate over other forms of steel-sections is that it provides ample bearing against the sides of the shaft, together with sufficient strength to take care of any bending stresses due to the settling of the strata, while it is also admirably adapted to resist compression from the action of the shaft-walls on the wall plates.

Owing to the readiness with which it may be molded to form, reinforced concrete is the best material for the construction of elliptical shafts. Steel lends itself more readily to the construction of rectangular shafts, and in that way is the exact substitute for wood. The Carnegie Steel Co. does not furnish steel mine-timbering fabricated ready for use in shaft-work. Quotations, however, will be made by the American Bridge Company.

Inasmuch as steel mine-timbers are fabricated complete in the shop, they are ready for erection when they reach the mine-face, and no further cutting or fitting is necessary. Erection, therefore, is quite simple, and no other tools are needed than wrenches. The usual method of erection is to assemble the three pieces complete on the floor, bolt the connections together, and raise the set into position, either by main strength or by a line thrown over the collar and attached to a snatch-block fastened at some convenient

graphite-paint be applied thoroughly as a field or second coat to protect the shop-coat and to fill up any vacancies or voids. The theory which underlies this recommendation is the use of practically inhibitive pigment to prevent the inception of corrosion in the steel, and the use of a second coat to protect the first from atmospheric and temperature conditions. Re-painting within the mines should be done on clean surfaces, absolutely free from rust, paint-skins, or dirt. It is not sufficient to apply a new coat of paint over an old paint-surface under which traces of corrosion already appear.

The book is handsomely illustrated, and is replete with tables showing elements of structural sections, allowable loads on various shapes, weights, bolts, comparative tables for wooden columns, struts, beams, and the like, together with all the engineering data for making the needed calculations, and other useful tables.

MAKING A HARBOR

At the entrance port in France for our expeditionary forces the United States Engineering Army has transformed in the last six months what was then an insignificant shipping point, with facilities for only a half dozen vessels, into a harbor that rivals the greatest American port. Machinery and materials costing \$40,000,000 were available. The engineers dredged the shallow channel and made a deep water-way. The debris filled in marshes that were covered with miles of piers and warehouses. Now 60 steamers can load and discharge their cargoes at one time. The largest railroad yard in France has made the war zone tributary to this port. Miles of switches and hundreds of train-crews are busy handling the food and supplies for the Army. Shops and round-houses are ready to keep the rolling-stock in good repair. Many battalions of engineers were required to build this distributing centre in so short a time. This new harbor was planned and the improvements were all made by engineering soldiers. Engineers are the pioneers of an army; they make the way possible for the advance of infantry and artillery; they are the skilled workmen of the army. The First Replacement Regiment of Engineers, stationed at Washington Barracks, D. C., trains men for the different organizations of the United States Engineers. The personnel of units in the Engineering Army is similar to that of an industrial organization. Each man in the army applies his technical knowledge to solving military problems. A soldier can follow his chosen profession in the army as well as the man in the industrial world.

HIGH EFFICIENCIES IN MOTOR-DRIVEN WATER-WORKS PUMPS

Many pumping problems are most conveniently solved by electric-driven pumps. Such pumps are a peculiarly desirable load for central stations, as they operate either at full load continuously, or in some cases are operated only during periods of light load, thus helping to fill up the 'valleys' in the load curve. Where centrifugal pumps are operated by power purchased through a meter, careful attention is likely to be given to efficiency, as a slight gain in efficiency will in a short time amount to more than the cost of the pumps.

Equipment recently installed at the McCarren pumping station of the St. Paul water department, included two 12-in. motor-driven centrifugal pumps. The specifications required that each unit should be guaranteed to deliver not less than 5000 gal. per minute against a total head of 171 ft., and not more than 5500 gal. against a head of 158 ft., the overall efficiency from 'wire to water' to be not less than 72% when pumping continuously at either of the

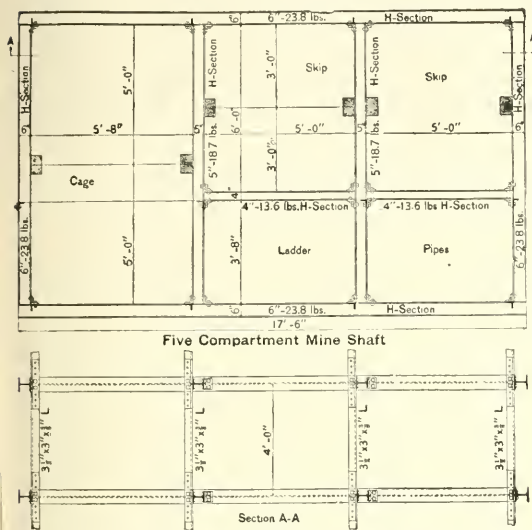

FIG. 5—TYPICAL RECTANGULAR STEEL-FRAMED MINE-SHAFT

point. Three-piece gangway-sets have been erected complete and wedged in place in eight minutes.

Preservation of Steel Mine-Timbers. The economical use of steel in mines requires a like degree of care for its preservation as accompanies its use above ground, although conditions underground are not nearly so severe, as the steel is not exposed to alternations of high and low temperatures, dryness and wetness, strong light and darkness. The base-plates should be set in the dry. Where they come on the edges of ditches, it may be desirable to set them on low concrete piers. All steel in mines should be well painted and kept painted. The pigments should be good and applied with care. Carbon paints in whose manufacture sulphuric acid has been used, and oxides of iron manufactured by chemical processes, or recovered as a by-product of metallurgical processes, are to be avoided. A metallic paint should be used for the first or shop-coat by reason of its adhesive qualities. The second coat should be a moisture excluder.

For the best service it is recommended that the steel be painted at the shop with a mixture of red lead, oil, and asbestine, in the proportion of 15 lb. of red lead and 2 lb. of asbestine per gallon of pure raw linseed oil, with sufficient japan dryer to work well; and that a first-class

heads and deliveries. It was further required that when delivering against a reduced head of 140 ft. the motor should not be overloaded. The bid of the Northwestern Electric Equipment Co., of St. Paul, which was accepted, offered pumps manufactured by the De Laval Steam Turbine Co., of Trenton, N. J., and synchronous motors of the rotating field type, manufactured by the Electric Machinery Co., of Minneapolis. These were guaranteed an efficiency of 74.3% at heads of either 158 or 171 ft., and an overall efficiency of 73.7% at 140 ft. The motors receive three-phase, 60-cycle current at approximately 2200 volts, and drive the pumps at 1200 r.p.m. They are so designed that they can be started by the application of alternating current to the armature windings. In normal operation they are supplied with exciting current by direct-connected exciters of 1½-kw. capacity. The pumps are of the De Laval single-stage double-suction volute type, having 12-in. suction and discharge nozzles. No diffusing vanes are used.

After erection, both units were subjected to complete tests to determine both efficiency and head-capacity characteristics. Before the official tests were run the impellers had been turned down slightly in diameter, due to the fact that the motors were operating at 20 r.p.m. above rated speed. All instruments were carefully calibrated. The quantity of water delivered was measured by a 30 by 13-in. Venturi meter, supplied by the Builders Iron Foundry Co., of Providence, R. I.

On motor No. 403,115 the following efficiencies were obtained: full load, 95.5%; ¾ load, 94.9%; ½ load, 93%; and on motor No. 403,129: full load, 95.3%; ¾ load, 94.6%; ½ load, 92.5%.

The efficiencies obtained on the pumps are high, considering the comparatively small capacity and the high head. Pump No. 25,651, at a capacity of 6527 g.p.m. shows an efficiency of 81.8%; and at 4097 g.p.m. an efficiency of 77%. Or, for a reduction in capacity of about 37%, there is a reduction in efficiency of only 5.9%, which must be considered very good for a centrifugal pump.

ROBB ENGINEERING WORKS, LTD.

The International Engineering Works, Ltd., has received authorization through letters patent of the Dominion of Canada to alter its name to the Robb Engineering Works, Ltd., under which title it will conduct its business in future. The organization of the company will remain as heretofore. The object of the change in title is to identify the business more closely with the established reputation of the Robb engines, boilers, and other products, known under that trade-name throughout Canada, the United States, and other countries. The concern is now engaged extensively in the manufacture of war-products, but it has not been neglectful of the needs of its former customers, and it has made a special effort to be in position at all times, so far as the war-demand will permit, to supply repair parts for the Robb engines and other equipment bearing the Robb name-plate. The company has adopted a policy of consideration toward private business, on liberal terms, keeping in view the certainty that the War will end some day, and that it will then be agreeable to have retained the goodwill of its former customers, and to be in a position to take advantage of the extensive development that is expected in the Canadian provinces. The circular announcing the new designation of the company has been issued over the signature of D. W. Robb, vice-president and general manager, Amherst, Nova Scotia.

'Duplex Doings' for March briefly describes various hard tests on machines made by the Duplex Truck Co. of Lansing, Michigan. Several feats in deep snow show what these trucks are capable of doing.

COMMERCIAL PARAGRAPHS

Bulletin 236 of the Walter A. Zelnicker Supply Co., of St. Louis, lists rails, locomotives, cars, tanks, and general machinery in stock.

American Refractories Co., manufacturers of chrome and magnesite brick, etc., has moved its head office from Joliet, Ill., to Union Arcade Bldg., Pittsburgh, Pa.

The Hyatt Roller Bearing Co., of New York, states that 21 big buildings at Newark, N. J., did not give its factory sufficient space for manufacturing bearings. They needed the building in which the firm was formerly situated, so the Industrial Bearing Division has been moved. The completely equipped engineering and sales offices are now in the Metropolitan tower, New York.

Tartarian & Pratt, of Los Angeles, California, have issued, for free distribution, a handy sheet of determination tables for commercial minerals, giving the characteristics of 65 species. A useful feature of the tables is a co-ordinate system for approximate identification of the mineral, based on the scale of hardness and the color of the streak. This particular form is original, and has been copyrighted by G. H. Pratt and H. V. Kleist.

Tierra del Fuego y Sus Turberas. By Guido Bonarelli.

Anales de la Seccion Geología, Mineralogía y Minería del Ministro de Agricultura, Rep. Argentina, Tomo XII, Num. 3, 1917.

The Director of Mines of the Argentine Republic has just issued this bulletin, prepared by Dr. Bonarelli. As a geological study it is admirable, both from the matter presented and the manner of treatment. It is a scholarly discussion of peat on the island of Tierra del Fuego. It is, moreover, a scientific study of peat, viewed in its broad aspect as a "geological phenomenon of the present epoch," as the author aptly puts it. Accordingly, the relations of peat to both climate and geology are discussed in great detail, as a consequence of which the author has given an account of the geology of Tierra del Fuego, and it turns out an extremely illuminating contribution. His study of the great batholith, which is responsible for the formation of this archipelago, is an interesting exposition of the various processes involved in a batholithic invasion of the earth's crust, and will be of broad interest to geologists in general, as well as proving useful to economic geologists interested in the gold and other mineral deposits of the islands. Six distinct types of peat are recognized: that resulting from the sphagnum moss; that coming from accumulations of hypnum; the forest peat (turba de bosque); 'carex' peat, formed by the remains of many species of the family of sedges generally mixed with types of moss and water-plants; the cotton-grass peat, resulting from the marsh-sedge division of the cyperacea; and lastly the lagoon peat. The relation of some of these types to their geologic environment is shown to be a close one. Furthermore, the special qualities of the different types is also brought out, and the possibilities of utilizing some of them for obtaining fibre is significant of like possibilities elsewhere. The book is accompanied with an extensive bibliography, which adds to its interest and value.

Gold output of the Rand in February was 659,759 oz., compared with 721,321 oz. a year ago. The recent floods and a short month contributed to this decrease. At the beginning of March there were 181,066 natives employed at the gold mines, a drop of 10,000 compared with this period of 1917, but a gain of 4640 over January 1918.

LISTS of honor are padded with the names of men engaged in civilian work. Thus the Institute's list of members "in military service" includes the gentlemen of the Naval Consulting Board, of the Fuel Administration, and the like. These men are doing patriotic work of unquestioned value, but it is a mistake to rank such service with that of the man who takes his place at the battle-front. Disguise it as we may, the supreme sacrifice is still that of risking one's life in fighting the enemy on the field of battle.

IS it not high time that all public feasting, drinking, and dancing cease, or be made to cease? In London or Paris there may be good reason for keeping restaurants and theatres open, for the gladdening of the gallant soldiers on leave, but for communities so far from the War as ours there is no excuse. If recruits need it, well enough; but the civilian population should show some realization of the fact that we are at the crisis of our fate; they can show it by abstaining from extravagant living and irresponsible gaiety.

PARTICIPATION of American capital in the development of the Rand goldfield is now assured by the acceptance of the tender for the lease of mineral rights on the Rietfontein West ground by the Anglo-American Corporation, to which we referred in our issue of November 24, 1917. At that time we stated that American capital in the corporation was represented by Mr. William B. Thompson, who is supported in this new departure by the Morgan and Rockefeller financial groups, who are acting with the Consolidated Mines Selection Company, identified in the minds of many of our readers with the names of Messrs. Walter McDermott and W. L. Hounold. The Rietfontein West undertaking involves a capital of \$7,000,000 and the South African government is to be paid royalty on a sliding scale.

AMONG other methods for stimulating the production of the secondary minerals in California, the committee on geology and mineral resources organized under the State Council of Defense is exhibiting specimens of types of ore and of the rocks associated with them, so as to aid prospectors. Reference should be made to Professor George D. Louderback in the University of California, at Berkeley. Here we may mention the sinister

fact that sundry deposits of useful ores, such as those of chrome, have been withdrawn from exploitation through purchases effected by German sympathizers, apparently to prevent production. Information concerning such cases should be given either to the Council of Defense, or, better, to the Intelligence Department of the U. S. Navy in San Francisco.

ANTHING explaining conditions at the fighting front is keenly interesting at this time. We are particularly glad therefore to be able to publish a careful and illuminating article on the geography and geology of the Somme battlefield by Mr. Bailey Willis, Professor of Geology in Stanford University and head of the Mining Department in an institution that has contributed so many greatly useful men to the special work demanded by the War. Stanford has struck a strong clear note—like Harvard and Princeton—from the very beginning of this world crisis, and by doing so has proved herself, beyond anything measurable by mere money and numbers of students, a real university. Dr. Willis has been a close student of the military operations on the Western front, and in his article he gives the reader a simple straightforward description of the physical conditions modifying the movements of armies over the terrain that is now the scene of colossal conflict. The maps will be welcomed.

REQUESTS for information and advice come to us frequently, in person and by letter, from members of the profession desiring to offer their services to the Nation. To those that are of military age, that is, less than 40, we advise to enlist at once, for that is the direct way to effective service. This does not necessarily mean serving as a soldier in the trenches, but it does place the applicant on a proper footing with those in authority. As soon as a man enlists, he is asked to state his education and training, with a view to allocating him to the work for which he is best fitted. Every effort is being made to use men according to their special aptitudes; thus a chemist is likely to go into the ordnance department and a miner into an engineer regiment. Those that are too old for active service should apply through their friends, for personal character is of the greatest importance in recommending individuals for responsible positions. It is a pity that an information department for

volunteers has not been established in every large centre of population, but, in default of such a bureau, each man must do his best to find his proper job, and in seeking it he must retain his good temper, on which severe demands are likely. Where there is a will there is a way; no man need sulk in his tent if he be eager to serve.

‘WILD-CATTING’ is a term with a blemish that is hard to erase. We concede the significance of the contention offered in discussion this week by Mr. Walter Stalder. He avers that the over-production of oil in California for 1914-15 was achieved by ‘wild-cattling,’ and that all past production was made possible only by such ventures. When an individual undertakes to drill a well where conservative operators anticipate no useful result, he may be dubbed a fool—until he wins—but he is not a ‘wild-catter.’ Depreciation is implied by that name; extravagant misrepresentation of the probabilities for purposes of stock-selling; the absence of frankly confessed pioneering. The world applauds initiative; it lies at the bottom of national growth; it is to be encouraged as a necessary virtue in a virile people; but to apply to it a discredited name is to discredit the thing itself. The company that denies or minimizes the risk when soliciting capital is a ‘wild-cat,’ but the honest venture deserves the meritorious title of ‘pioneer’ or ‘prospector.’

THE hanging of the German, Robert P. Prager, at Collinsville, Illinois, was a hideous crime and a disgrace both to the State and to the Nation. All such acts of lawlessness, like the Bisbee and Butte affairs, are a blow at democratic government and should be reprobated by good citizens. No good, but much harm, comes of them. The people need not think that they can help the national cause or make America safer by assuming to mete out punishment beyond the pale of law. The Government has dealt with the German in our midst according to the light of the civilization that we profess, and in the spirit of the golden rule. It has offered the hand of fellowship and brotherhood, but, because it has been spurned so often, the righteous wrath of an outraged Nation is being shown in sterner methods and sterner laws. The sovereign will of the whole people shall be expressed, in a legal way, with ample energy and in ample time to prevent harm to our cause from those that are unmindful of their duty to a land that has welcomed and mothered them in the past. Meanwhile every good democrat will abide by the law.

THE Boletin Minero for January of this year, the official organ of the Department of Mines of Mexico, has just come to hand, and in it we find a long list of mining properties declared ‘caduco,’ that is, lapsed, applying to nearly every State in the Republic. It may be well for American owners of Mexican mines to scrutinize this list, which covers those declared forfeit from September 20 to November 16, 1917. The name of each property, its title-number, and its municipality are given. The same issue of the bulletin contains an official

list of mining companies in Mexico that are in operation at the present time. The showing is larger than the reality, for the properties reported as operating in 19 different States are in a great many cases doing only as much work as may be necessary to avert confiscation. Without sufficient rolling-stock on the railroads, with no means for obtaining necessary supplies nor for shipping ores steadily and in large quantity, save as facilities of transport are afforded when possible by the two leading smelting concerns, it is not feasible for mines to produce on a scale approximating the normal.

REFERRING again to the American Metal Company and its German control, it is noteworthy that early this year five directors were appointed by the Government to represent the stock that had been taken in charge, soon after the United States declared war, by the custodian of alien-enemy property, Mr. A. Mitchell Palmer. These directors are Henry Morgenthau, George McAneny, Lewis L. Clark, E. C. Converse, and A. W. Mellon. Mr. Morgenthau was born in Germany, but he came to the United States when a child and has served his adopted country in various ways, the most recent being as ambassador to Turkey. He is a lawyer by profession. Mr. Converse is a prominent financier, identified with the Guaranty Trust Company, the United States Steel Corporation, the Inspiration Consolidated Copper Company, and other notable enterprises; Mr. McAneny is executive manager for the New York ‘Times’; Mr. Mellon is president of the Mellon National Bank of Pittsburgh; Mr. Clark is president of the American Exchange National Bank, New York, and a director of many enterprises, including the New York and Honduras Rosario Mining Company. It is significant that Mr. Kuno B. Heberlein has resigned as president of the Compañía de Minerales y Metales and of other Mexican subsidiaries of the American Metal Company. He is reputed to be a trusty American and we presume that his resignation is in the nature of a protest against the inimical action of his co-directors in Mexico. As regards the South American connections of the American Metal Company, we are informed on the best authority that the Ore Trading Company, at Santiago, for example, is German from top to bottom, but that by way of camouflage it is registered in London as a British company. The London firm of Henry R. Merton & Company, with which the American Metal Company was closely allied, got into trouble with the British government early in the War and was compelled to re-organize, the German holdings being acquired by English capitalists, so that now the firm is wholly non-German. It is a pity that the name was retained, for that links it still with the Mertons (real name Cohen), of Frankfort, and the Metallgesellschaft, and fails to make it clear that the firm is now in the hands of Messrs. H. Gardner, H. A. Barton, Robert S. Lindley, and other Englishmen. The War is exercising a profound influence on the control of the international metal-market and before it is over we expect to see further changes not only of nationality, but, what is more important, of combination in restraint of trade.

The Crisis

At a moment like this, when the destiny of nations is in the balance and our own kith and kin are holding the line against the concentrated attack of the Enemy, it is difficult to discuss the technical questions normally our subject. From hour to hour, as the screaming headlines of a puerile press meet our anxious eyes while we remain in ignorance of the real facts of the critical struggle, we realize to what insignificance the ordinary happenings of daily life are reduced. Even the exciting experience of our earthquake with its resultant conflagration, just twelve years ago, seems petty in comparison with the events that we are compelled to witness at a distance and as through a glass darkly. We are suffused with sentiments of gratitude to the brave men that are battling for our hearths and homes amid the crash of exploding shells and the reek of deadly gases; we offer hourly homage to those that are asserting their manhood against the onslaught of the hated Prussians and the peoples whom they have so easily perverted into international brigandage. To the brave British that have borne the brunt of the recent attack, to the gallant French that have come so promptly to their aid, and to our own fine boys, who at last have been permitted to take their proper place in the ranks of the defenders, to each and all we stand in respectful salute. The end is not yet. Many days of bitter fighting will ensue before the issue of this long-drawn battle is decided. More anxiety will be our portion; but let us remember what Napoleon said, when somebody deprecated the British as soldiers: "They lose every battle except the last." Let us remember how the French smashed the Prussians and the Austrians time and again when properly led by Napoleon and his marshals. And as for our own representatives, we need no reminder, although history is eloquent enough; we know them, that suffices, and in that knowledge we rest secure that neither over them, nor through them, can the Hun and his cohorts go. They shall not pass! We abide the event in quiet confidence that, whether today or tomorrow, now or next year, the German tide of militarism will shatter itself against the walls of freedom and at last the world shall emerge from this nightmare of horror, this "sword and fire, red ruin, and the breaking up of laws."

The Liberty Loan

In our last issue we printed sixteen pages advertising the third Liberty Loan, this space having been given by seventeen different manufacturers for this patriotic purpose. Public interest in the present issue of bonds to the amount of \$3,000,000,000 is splendidly keen, and we anticipate a proper response. The issue should be easily over-subscribed, of course, for the people of the United States have both the money and the will to loan it to the Government for the furtherance of this righteous and decisive war. After all, those of us that subscribe for a gilt-edged security at a good rate of interest are not

doing anything remarkably self-sacrificing, are we? Contrast such an advantageous business transaction with the incomparably greater hazard that is being taken by our gallant soldiers and sailors. Consider what the British people are doing at this time: calling upon their manhood up to 50 years of age to serve in the armies now locked in deadly contest with the oncoming Enemy. What is the loan of a few billion dollars as compared with the sacrifice of men of mature age, of heads of families supporting not only their own children but in most cases an aged parent or a less fortunate brother or sister of advanced age. Men of 50 have large responsibilities, they are near the close of an active career; to them actual participation in warfare means the end of everything for which they have worked and planned. Yet the older manhood of Britain is as willing to make the same supreme sacrifice as their sons who rushed to enlist in the early days of the War. We bow our heads in deep respect to these gallant men, and we feel deeply that the secure investment of our savings for the common cause is a small thing to do and one therefore that can only gain comparative dignity by being done promptly and cheerfully. The President has spoken for us, we have accepted the challenge of Germany, realizing to the full her fell purpose, which was exhibited with cynical brutality only recently in Russia—as if to remind those that had become callous to the sufferings of Belgium, of Serbia, of Poland, and of France, what is in store for them if the Prussian heel treads farther across the earth. Our resolve, says the President, "shall appear in the utter sacrifice and self-forgetfulness with which we shall give all that we love and all that we have to redeem the world and make it fit for free men like ourselves to live in." . . . "There is, therefore, but one response from us: force, force to the utmost, force without stint or limit, the righteous and triumphant force which shall make right the law of the world and cast every selfish dominion down in the dust." Those that cannot contribute to that force by fighting personally on the battlefield must aid in the other ways left to them. The least we can do is the best that we can do. Do it now.

Control of Mineral Production

Metal miners and smelters seem to be unduly alarmed over the emergency bill that provides for "encouraging the production, conserving the supply and controlling the distribution of those ores, metals, and minerals that have formerly been imported, or of which there is or may be an inadequate supply." As originally drawn the measure included iron, copper, lead, zinc, and other common metals, but it is now restricted to antimony, arsenic, chromium, graphite, magnesite, manganese, mercury, molybdenum, platinum, pyrite, tungsten, tin, sulphur, and alloys and chemicals derived from them. It would have been wise at the beginning of our organization for war to have appointed an independent committee to co-ordinate the mineral industry, but this was not done. Division of responsibility for the supply of any class of

material hampers efficient correlation of the work of production and distribution. Nowhere has this been more conspicuous than in mobilizing the chemical industries. There is talk even yet of gathering these under the control of a single committee, but confusion and delay would follow such a change. The final result might be advantageous, but the loss of effectiveness during the period of transition would diminish the value of such a belated reform. The sulphuric acid business has been considerably muddled by apportionment among various departments and committees. Almost every industry is dependent in some manner upon sulphuric acid; the Department of Agriculture is vitally concerned in the use of it for making fertilizers; the War Department is equally solicitous over the manufacture of explosives, into which sulphuric acid enters. It is easy to surmise what difficulties, delays, and conflict of interests would follow from placing the administration of this chemical under a new organization, unfamiliar with the arrangements previously made for production and distribution. It would halt preparation in a thousand directions, disastrous to the best interests of the Nation, but gratifying to sympathizers with the Enemy. The same argument applies to the sudden consolidation of the mineral industry under a so-called dictator at this time. The idea was rejected promptly by the committees on mining both in the Senate and in the House, which was the reason for limiting the bill to such materials as mainly and normally come to us from abroad. If there be any fear lest an attempt be made to widen its application, on account of the broad language in which the purpose of the measure is stated, its scope can be more narrowly defined by amendment. There is no doubt of the utility of doing what the bill proposes. The Committee on Mineral Imports and Exports, through its chairman, Mr. J. E. Spurr, has declared that the main problems to be solved are those of labor and transportation. We possess the resources, but these must be developed in the places and to the degree that the output can be made available where most needed. It would be foolish, for example, to increase the production of Californian pyrite and undertake to ship it across the continent when the Appalachian resources, near the Eastern centres of acid manufacture, can be made to yield more abundantly. On the other hand, the shortage of manganese and chrome ore necessitates intensive development of Western deposits, and the means of transportation must be arranged. The last example illustrates the wisdom of another provision of the bill whereby the administrator of these essentials is permitted to enter into contracts for two years, and even to advance funds for plant and equipment. The sum of \$50,000,000 is provided for such encouragement of these special industries. Many of them would not be undertaken without aid of this kind, because the unfavorable conditions of price and transportation that prevented their development before the War would crush them after the War. The object sought is precisely that of encouraging enterprises at present largely non-existent, but apparently capable of supplying our needs in the present crisis. In many instances a large amount of

initial exploratory mining must be done to open the mineral deposits for production; expensive equipment will be needed, roads are to be built, and quarters for operatives to be erected. The preliminary outlay must be covered by guaranty of a market at fair prices long enough to return the capital with profit. High prices alone are not sufficient. This is not commerce, it is war! The object is to provide insurance against having to shut-down steel works for want of manganese; insurance against starving the land for want of fertilizer, so that we shall not confront famine; insurance against shortage of ferro-alloys so that the capacity of our factories shall not be lessened for lack of high-speed tool-steel, nor the life and efficiency of our guns reduced for want of resistant linings. Other features of the measure appear equally necessary. The President is authorized to make such regulations as may be essential, not only to promote production, but to prevent waste, deterioration, hoarding, monopoly, or discrimination. He may require licensing of manufacture, storage, mining, and distribution of the substances mentioned, and he is given power to fix prices. He may also requisition and assume control of any idle deposit, mine, smelter, or plant "to develop, or cause the same to be developed or operated in such manner and through such agency as he may direct." The bill is comprehensive in its provisions for securing the rights of owners in the proceeds of the development of their properties, and in prescribing penalties for practices that might affect injuriously the output and proper distribution of the commodities listed. Here we may suggest that the more immediate method of encouraging the production of sundry essential minerals is to fix a price for them, or for the metals derived from them, for a definite period, say, two years, so as to justify the outlay of time, energy, and money required to find the mineral deposit and bring it into fruitful development. The loan of money to prospectors and small operators—a large-scale grubstaking—might be another way of stimulating production, but we consider it likely that the stabilizing of prices would suffice for the purpose in hand. As to the control of these necessary operations, it would be a mistake to create a metals dictator at one stroke, but that is not contemplated. The President may delegate his authority to any department, bureau, committee, or other agency, in his discretion. The opinion prevails in Washington that the functions of the War Industries Board might be enlarged by assuming the responsibility. This proposal has much in its favor. The Board already controls several branches of the metal industry; it is organized and ready to proceed; it is an independent committee, having large freedom of action and initiative, in this respect resembling a department of the Government. It is conceivable that the administration of the mineral industry, now divided between various functionaries, might be assembled under the direction of this single organization. In this way consolidation could be effected without violent disturbance of existing arrangements, and it would contribute rationally and logically to the greatly desired end of establishing a Department of Mines, with a Cabinet officer.

DISCUSSION

Buying Combinations in the Metal-Market

The Editor:

Sir—In your issue of January 19, 1918, in an article under the above heading I note you have included the name of Goldsbrough Mort & Co., Ltd., in the German buying combination.

This is quite incorrect. Goldsbrough Mort & Co. have never had the slightest connection, or association, with any German metal-buying combination, nor have they ever been connected, directly or indirectly, with any metal business, their business being entirely that of wool, grain, and skin, brokers, and bankers.

I shall be glad if you will make the correction in your next issue.

Goldsbrough Mort & Co., Ltd.

per A. Lingrove, Secretary.

Melbourne, Australia, February 26.

[We accept the correction. The chart to which reference is made was a facsimile of the one published by the U. S. Federal Trade Commission.—EDITOR.]

Native Tungsten

The Editor:

Sir—I wish to call to your attention the discovery of native metallic tungsten on the Prefensia claim near Albion, Idaho. This might be of interest to mining men, especially those working tungsten properties. The specimen submitted to me for analysis weighed two pounds three ounces, of which over one-half was metallic. The capping was on a base of tungstite, which gradually ran into the wolframite series. The average of three analyses gave the following composition: tungsten 98.7%, iron 1.2, chromium 0.3, with traces of nickel, cobalt, copper, and manganese. This is to my knowledge the first specimen of any size of native metallic tungsten.

R. FRANKLIN HEATH.

Spokane, March 30.

[It would be of great interest to have this occurrence confirmed by samples taken by competent and well-known observers. Mr. Heath's accuracy as an analyst we do not question; but he does not assume responsibility for the specimen analyzed. It would be most unlikely that tungsten would meet conditions near the surface favoring reduction. It is apparently a magmatic emanation in oxide or sulphide form. The existence of chromium, nickel, and cobalt, essentially derivatives from

a basic magma, in association with the tungsten, equally characteristic of acidic rocks, throws further doubt upon the specimen as a natural product.—EDITOR.]

Nickel-Copper Steel

The Editor:

Sir—I have noticed with a great deal of interest the recent references in your magazine bearing upon nickel-copper and copper steel, that is, steel containing a small amount, say, about 2% of copper, or nickel and copper combined.

Just recently I have been interested in watching the progress of a practical test—something beyond mere laboratory experiment along this line. This test has up to the present time produced 'assay-prills' weighing some 80 tons, and I now have before me, in a paper read before the Canadian Mining Institute at its last meeting, the data bearing upon the qualities of the product. This Nieu (Ni-Cu) steel, which I had an opportunity of watching through the process, from crude calcined nickel-copper ores, was produced not only from the raw ore, but from waste slags rejected by the nickel-copper producers of the Sudbury district, in Ontario.

As one who has developed a principle based on an older idea in metallurgical machinery, I am very much interested in the fact that some of these citations, recently made, go back many years. It was the knowledge of these old but abandoned tests that caused me to be decidedly sceptical as to the possibility of practically producing the nickel-copper-steel on a commercial basis. The early experimenters along any line are often a deterrent to advancement rather than an aid, for we are likely to conclude, as was my first impression in this particular instance, that the process must have been tried and turned down on account of impracticability. An inventor, such as Mr. Colvocoresses, has a great deal to overcome in giving reasons for previous failures or, if not failures, to explain the cause why certain processes were not before adopted. The answer is simple: either the capital was lacking or the inventor's genius was handicapped by his lack of faith in his invention, which was therefore temporarily lost to the world. In the present instance Mr. Colvocoresses backed up his invention by personal investment in his own idea, and should he make the success that I now predict for his process there will no doubt arise a swarm of claimants for priority of ideas. It is very much easier to say "I told you so" than to produce practical results.

It is the man who not only thinks invention but prac-

ties invention and accomplishes practical results, going beyond the mere formula of a thought, that the world needs. It is not only the thought of munitions but the munitions themselves that we need to win the war of advancement. There are plagiarists and infringers galore, but even these, if practical, are better than impractical thinkers who by only giving voice to their thought become obstructionists.

New York, March 30.

Professional Peonage

The Editor:

Sir—I often wonder, when I see the more or less relevant and irrelevant discussions in the technical journals in regard to the status of the engineer, whether the public in general knows or cares to know the injustice and unprofessional attitude that the employer assumes and maintains toward us. To say the least, we are the most intensively trained and the lowest paid of all the practical branches of human activity. I note that recently there is raised the question of the propriety of the men leaving an office, or employment in general, without first securing the permission of his employer. I do not feel that when a man can better himself that this system of unilateral ethics should interfere.

Permit me to submit for the information of those who do not know it that there is a 'gentlemen's' agreement that the employers are the ones who are to say whether a man shall have the opportunity to better his condition or not. I can sustain my contention that there is a collusion of many of the larger copper producers (and, mind you, it antedates the War and the present abnormal conditions) whereby no one in the employ of one will be entertained for a position in another without the present employer's consent.

Now, the injustice of this procedure is manifest, for it not only tends to discourage men so inclined from entering the profession, but it does more: it creates dissatisfaction in a force of men, and a profound contempt for such a shortsighted policy of arrogated authority. One of the companies under fire for accepting men from others without the prescribed permit (and it is respectfully submitted that we are or should be allowed both to employ and to be employed where our best interests direct) has been on both sides of the fence, depending on its particular interest on each occasion. It has taken men from others and it has complained when others have reciprocated.

Four and a half years ago a company wanted an engineer. I applied because the office in which I was employed had a most unbearable chief-engineer. I was turned down and the reason openly assigned by my prospective employer was this aforementioned gentlemen's agreement. There was no mincing of words, this was stated outright. A stranger to them was telegraphed for from another State. I immediately resigned my position and left the community, for I had fully made up my mind not to remain, and of this fact I unavailingly

acquainted the one whose employ I desired to enter. The same condition exists here.

One of my brother engineers has a large family. Not long ago he was offered a position at \$100 per month increase by a company in another camp. Reference was made to his present employer and he refused to let him go or raise his salary. He said that he did not want to break in a new man. Here we have a well-paid foreigner who prevents an American citizen from securing a position that will enable him properly to educate his family. I have others in mind but the above will corroborate my general statement. I feel that in the interest of enlightenment and fair dealing the above should be given to the reading public, for as surely as the sun rises in the east the lines are drawing closer and closer about us as professional peons. It is this kind of craven conduct that creates mutual contempt between employer and employee, arouses suspicion between man and man, fills the land with I. W. W.'s, and will eventually bring before us the situation of "divided we fall" because we have repudiated the doctrine of "united we stand."

AN ENGINEER.

Los Angeles, March 25.

Silver

The Editor:

Sir—The article on silver by Governor Boyle and Mr. Symmes appearing in your issue of March 23 may naturally be expected to attract a great amount of attention, considering the prominence of the authors. It seems a pity, however, that they should have fallen into error in a number of instances, especially with regard to a chronology of the facts set out. They state that last September when the New York quotation for silver was \$1.08½ (not \$1.09½) Great Britain placed an embargo on shipments of silver into and out of India. As a matter of fact, a British order prohibiting the importation of silver and gold into India, except for Government purposes, was promulgated in the previous July, and at that time it was a general belief in well-informed circles that the action was prompted by the fact that during the previous weeks England had received far below its normal imports of the metal. Estimates place the actual imports into England during that period as not over 200,000 ounces.

The article gives the impression of an extremely narrow viewpoint and the contention that Great Britain is placing restrictions on silver because of a desire to increase the purchasing power of a pound sterling in the East. As an accusation it scarcely bears analysis. A profit of \$51,000,000, which the Indian mint has made on seigniorage, is surely an insignificant item in the trade between India and Great Britain. Unless I am very much mistaken, the profit made by the Indian mint does not benefit the British treasury in any manner whatsoever. If the price of silver rises the increased purchasing power of the Orient that necessarily follows would seem to be of much greater benefit in British trade with

the Orient than is possible from any other consideration. It is Great Britain that furnishes the ships to handle the Oriental trade and the more prosperous the East is the greater the benefit of the mother country.

C. S. HERZIG.

New York, March 29.

Increasing the Production of Oil in California

The Editor:

Sir—It is surprising to note that the impression is being, and has been, conveyed throughout California that all of the possible oilfields of this State are known and are at the present time either fully or partly developed. It is even more regrettable that the notion should exist that all future production must come from present known fields or extensions of them.

Being aware that it has been the American pioneer spirit that has found and proved new fields in the past, and being slightly acquainted with some of the geological conditions in untested areas throughout this State, I venture to express an optimistic view.

When O. D. Barton first went into the Lost Hills to prospect for oil he operated with a small rig capable of drilling only to a shallow depth. This he used in the face of adverse comment and the knowledge that the best previous technical calculations had determined a depth beyond reach of his drill (U. S. G. S. Bull. No. 406 p. 207) for the only oil-sand then considered as having a prospective value. There was genuine surprise in California when his well, at 527 ft., proved a good producer. The facts of the discovery were that he had used his own judgment regarding the interpretation of the oil indications in the immediate vicinity, he had faced all the hardships connected with getting such a venture under way, and he was rewarded by discovering favorable conditions for the occurrence of oil that had not been surmised before in that locality. Whether or not he previously realized all the phases of his venture is not known to me; nevertheless, the desired production was obtained, and the example here set may illustrate in a way the mistake made by discouraging wild-cat prospects too hastily.

Oil was found in the Lost Hills as an accumulation in overlying porous beds near the line of an unconformity (Bulletin 69, California State Mining Bureau). This relation exists in other fields south of the Lost Hills as far as Sunset and possibly is limited only by the extent of the San Joaquin valley and certain formations that exist through at least the south half of that depression. This possibility has been recognized, but it has not, as yet, been thoroughly tested. It, therefore, forms the starting point for some important future discoveries throughout a large area around the rim of the valley and in other parts of California. Until it has been investigated thoroughly both from a geologic standpoint and with the drill there is much room for new and important discoveries.

The development of the Santa Maria and Lompoc oil-fields has proved that oil can accumulate in the cracked flints and shales of the Monterey shale series. Just how productive some of the best wells in this shale have been is indicated by the fact that one well that came in at 8000 bbl. per day in 1904 was making at the rate of over 200 bbl. per day in 1915; moreover another well developed in the same series of beds came in at 1675 bbl. in 1906 and is still producing freely. The shale and its associated beds, which give rise to this oil and form a reservoir for its accumulation, are widespread and frequently thick, throughout large portions of this State from Point Arena in Mendocino county to near the Mexican border. Wherever found oil indications are manifest somewhere in the immediate neighborhood. While some of these shale areas have been tested in a desultory manner they have by no means been thoroughly investigated or prospected, largely because of the difficulty in drilling the hard flint beds associated with them, partly because of poor financing, and partly because of past over-production of cheap oil. Until these shale areas have been investigated and tested, there is still room for other important oil discoveries as at Santa Maria and at Lompoc.

Deep drilling in the main Santa Maria oilfield has developed the fact that beneath the productive cracked flint and shale beds lies some true sand (the Vaqueros sand) that is productive. This oil-sand has considerable extent throughout portions of Santa Barbara county and adjacent areas. It has not, as yet, been systematically investigated. At the outcrops the sand shows unmistakable indications of oil at many places.

In northern California is a wide extent of beds deposited during Cretaceous time. In places these beds have developed seepages of a paraffine oil. The geological horizon of these seepages is somewhat similar to that of certain oil-horizons in Wyoming. Work of a preliminary and cursory character has been attempted, as yet without success. To my knowledge, however, the entire Cretaceous region of northern California has not been studied thoroughly. Until it has been so studied and tested no one has the right to denounce the area. From what has been observed in a preliminary way it appears that some of these Cretaceous districts invite further investigation.

There has been much wild-cattling throughout the State since the first attempts to produce oil. Where success has followed large fields have been developed; where unsuccessful the territory has generally been condemned. Before rejecting any previously tested area it has been found good practice to get a history of the developments and to ascertain, if possible, any reason other than the lack of oil for abandonment. It is possible that several prospective fields have been given an unwarranted 'black eye'. For example, I had occasion to investigate one prospective field where there had been some previous drilling. I found that the field had been condemned by wells drilled at various times, none of which produce commercial oil. Closer observation disclosed that every well had been drilled near the outcrops of the oil-sand

and that the only logical place for testing the district was an anticline involving the oil-sand and situated but a short distance away. This field has so far been entirely neglected.

Again, before denouncing the future possibilities of Californian fields by noting the decline in production in 1916, the present draft on the stock of oil and the small amount of new territory brought in during the last two years, it is well to inquire into the reasons for the present conditions other than the withdrawal of Government lands and the setting aside of naval reserves in the Buena Vista and Elk hills. These facts have a most important relation to the failure to bring in much new territory during that period.

With the tremendous over-production of petroleum in California from 1910 to 1916 and in the mid-continental oilfields in 1914-1915, stocks of crude oil mounted continuously until there was 59,777,789 bbl. in storage in California in May 1915. For this over-production wild-cat wells were largely responsible. With a continued surplus production, prices ebbed and the operators found themselves on the edge of ruin. The situation was alarming, and to prevent disaster they adopted several remedies. All new drilling was discouraged, many producing wells were shut-down, new markets were sought, and all wild-cattling discouraged. The results have been as desired. Over-production has been stopped, prices have been increased, stocks have been decreased, and the minimum of new fields is being brought in, resulting withal to the prosperity of the producers, just as was directly planned by them before our entrance into the War.

Now, however, the War is making new demands and the reverse of these protective measures is desired. More oil is needed, a surplus in stocks is necessary, and it becomes a duty to increase production. This is an adjustment requiring time. Fortunately the operators' seven years of past difficulties have developed the best that there is in them and confidence is felt that they will meet the requirements. Just how they are commencing is indicated in a measure by the increase in production in 1917, over 1916, from 91,976,019 to 97,781,574 bbl., by the more careful conservation of oil, and by the bringing in of the one new field at Montebello.

Since this article has to do with wild-cattling, the new development of the Montebello oilfield is one of the best object-lessons in favor of that particular and necessary branch of the industry as a method of making up the necessary shortage. With stocks previously being depleted at the rate of 30,091 bbl. per day during 1917, this new field alone has produced enough to offset that draught at the rate of 10,000 bbl. per day in January and 12,000 bbl. per day in February 1918, and gives reason for a more optimistic belief in future possibilities. When it is further remembered that all past production from all wells has been made possible only through wild-cattling, the vital importance of this enterprise can be the better appreciated. It illustrates the high value of courageous initiative.

It is fortunate that large areas of prospective oil-lands

are owned by deed, patent, or grant, and are available for acquisition and testing. The circumstance is also fortunate that all of the Government holdings have not been classified as prospective mineral lands and withdrawn from entry. Idleness on the part of all operators is, therefore, not necessary, for want of prospective territory during the period that the legal and legislative snarls relating to naval reserves, lands withdrawn from entry, and Government receiverships are being untangled and re-snarled again in Washington. In spite of all these difficulties there is much to be done in wild-cattling new territory.

In this necessary branch of the industry, if prices can be maintained and the production absorbed, there is certainly much to be done in California in stimulating the operators. Although somewhat out of practice because of the inaction primarily due to the long continued low prices, there is surely enough of the pioneer spirit left among our operators to attack the problems at hand, using at the same time all of the available knowledge and experience gained through forced economies during the last few years. Montebello is a beginning, but other similar fields must be found. If but one in four or five new wild-cat areas prove productive, the record will not be poor, particularly when it is remembered that the high gas-pressure with the accompanying flush production of a new field acts as an offset to the failure in other areas tested. An honest failure in this branch should always call for praise as a worthy and patriotic effort and not for ridicule as is too often the case, for it takes grit to face the necessary risks, and in carrying on such enterprises the operator is doing a war-time service. If successful, his pecuniary reward more than offsets his troubles.

There is every reason to place the utmost confidence in the type of man that has so far survived the hardships of the Californian oil industry. Through his past hardships he has developed into an individual who can meet any oilfield difficulty and intelligently, energetically, and successfully solve it. When all operators strive for an object something usually happens in the oilfields. The small operator has proved himself a particularly active and successful worker in prospective territory in the past. Wild-cattling is a branch of the industry where he has really done brilliant work. With the larger companies now giving more attention to this vital necessity, the small operator also becoming interested, and in view of the large amount of prospective territory to be tested, there is abundant reason to believe that in addition to the new Montebello field other new fields will be brought in to increase the desired oil-supply and incidentally to demonstrate the true latent oil possibilities of this State as the clearest possible refutation of the pessimistic idea that all of the oilfields of California have been discovered.

WALTER STALDER.

San Francisco, April 2.

ELECTRICALLY smelted pig-iron is being produced at Porjus, Sweden, at the rate of 20,000 tons per annum. This plant yielded over 10,000 tons in 1917.

Geographic Suggestions of the Somme Battlefield

By BAILEY WILLIS

Look at the map of the battlefields of the Somme. In 1916 the British fought from July to November to drive the Germans from the ridge that extends from Combles to Thiepval. The area they won in four months fighting is the shaded area on the map herewith. No one can disparage the fight they put up, nor the German resistance. The British won because they were better men, better equipped, better generalled.

In 1918, fifteen months later, the Germans drove the British and French from the greatly larger area between the widely separated positions of March 22 and March 31. In ten days they accomplished, apparently, far

wear out the opponents. The retiring Allies sacrificed territory, towns, battalions, guns, so far as was necessary to accomplish their pre-arranged plan. Then the retirement stopped. The counter-stroke is due.

The man on the street feels that he is watching expert players in a game of chess, in which checkmate means death to nations—and they move mysteriously, planning far ahead to achieve victory through what seems to be a desperate gambit. What is the next move?

In war, as in chess, the players manoeuvre for positions and the lay of the ground may decide the issue. The withdrawal of the Allies is apparently such a ma-

BIRD'S-EYE VIEW LOOKING TOWARD LONDON AND THE NORTH SEA

more than did the British in four months, including the conquest of the heights that cost the British so dearly in 1916.

Are we to conclude that the Allies have weakened or the Germans become superior? There is nothing to support the suggestion except the bare fact of the change of position. We can dismiss it, for it is not true.

May we infer that Germany is desperate, and, like the Norse berserker of old, who relied upon brute strength and ferocity, has thrown herself upon the foe with irresistible violence to crush or be crushed? There is much of the brute courage in the German masses. They fight like the berserker. But German generals do not. They have planned far ahead. Desperate they may be, but mad they are not. Rather may we say that the Allies have retreated with a purpose. The German attack was anticipated. The overpowering offensive was met with that degree of resistance which wears it out, but does not

noeuvre, and it is worth while to study the ground better to understand the aim of the players in this fearful game of the People against the last of the Empires.

The board is the once checkered landscape of northern France, a plain and hill land, formerly of fields and orchards, now a desolate waste thrice swept by armies in retreat. Roads, bridges, houses, and towns have been blown up, and the very ground is pitted with shell-holes beyond number. Hell is not more desolate nor more agonized.

Two rivers, the Somme and the Oise, seven miles apart, flow parallel from the German line into the battlefield and there separate. The Oise runs straight on south-west toward Paris; the Somme winds in a great inverted S, north-west to Amiens and beyond. At Amiens the Somme is joined by the Arve, flowing north-west, and a little east of Amiens it receives from the north-east the "bloody" Ancre, which rises near

Bapaume. The flat river-valleys are swamps, passable by constructed roads, but otherwise difficult to cross with vehicles of any weight. Their general level is about 200 ft. above the sea.

The uplands also are flat, but extensive. They are low plateaus and the valleys are branching trenches sunk in them. Let us, for instance, fix our attention for the moment on Bapaume, the railway and highway centre that the English took from the Germans and surrendered to them in retreating before this last offensive. The town lies on a broad plain, with a general elevation of 450 ft. above sea-level. Near it rise four little streams, which flow north and north-east and are part of the headwaters of the Escault or Scheldt, one of the principal rivers of Belgium. They are the Exuette, Agache, the Sensée, and the Cojeul. Just east of Arras these streams are connected by canals with the Searpe in a plain whose general elevation is about 275 ft. above sea-level. From this plain, just north of Arras, rises the lonely height of Vimy ridge. The plain is that which has been described as the plain of Flanders, and the valleys lie engraved in the slope that rises toward Bapaume.

Just south of Bapaume are the springs that are the source of the Ancre. Their waters flow west and south, encircling higher ground, and soon sink into the deep trench across which the British drove the Germans in the battle of the Ancre, and behind which they have now taken their final stand in defence of Arras and Amiens. The heights enclosed by the Ancre were the scene of the battles of July, August, and September 1916. With them are associated the struggles for the possession of Combles, Ginchy, Contalmaison, Pozieres, and Thiepval ridge. The general elevation of these ridges is but a little more than 500 ft. They form a low crest, extending from south-east to north-west across the triangular plateau that is bounded on the west by the trench of the Ancre and on the south by the wider trench of the Somme.

Another point to which our geography may well be linked is Peronne, the town that lies at the crossing of the Somme with the highway from Cambrai to Roye and thence to Paris. At this point the river turns from north to west. It thus forms a great salient toward the German lines. In its course from the south and on toward the west it flows in broad marshes, crossed only at long intervals by the highways which once existed but now exist no more. And thus Peronne and the bridge behind it constitute a vital point in the retreat of an army forced back upon that town.

The country south-west of Peronne, lying in the arc west and south of the Somme and bounded on the west by the Arve, is in general a flat plain, with few slight elevations and comparatively little feature for defence. It is now wholly occupied by the Germans.

St. Quentin is a point on the Hindenburg line, the name of which is familiar to every reader of the newspapers. Like Amiens and Peronne, it lies on the Somme. The three cities are nearly in a straight line; Amiens on the west, Peronne in the middle, and St. Quentin on the

east. Between them the Somme makes the great double bend, first to the south and then to the north, that has been likened to an inverted S. This bend has already played its part in the issue of battles, and may play a still more important part in the fighting that is to come.

Let us now turn farther south to La Fere and Noyon. Both are towns on the river Oise, which flows south of west from La Fere through Chauny to Noyon, and then turns south-west toward Paris. The river-valley is again broad and flat, and is traversed not only by the meandering river, but by canals. The water-courses in themselves constitute an important line of defence, but in addition, the valley lies under the slopes of a plateau, which extends to the south and south-east, with an elevation of 500 to 700 ft. above sea. This plateau forms an escarpment that soon dies out toward the west, but is an important feature from La Fere to Rheims. It is the height that has been held by the French since the great German retreat of 1914. In the present attack the Germans have avoided it and have swung around its northern corner at La Fere.

Northern France is a land of chalk similar to the cliffs of England, and above the chalk are hillocks of sandstone. We have seen that there are two plains, the lower plain of the valleys, carved into the chalk, and the upper plain, which lies near the top of the chalk at its contact with the sandstone. The hillocks rise above the latter, as in the case of Vimy ridge and of the heights won by the English in the battles of 1916, between Combles and Thiepval.

The strata lie nearly flat. The chalk is not pure, but contains more or less clay and is interbedded with clayey layers. The sandstone also contains more or less lime. Under the wet climate of the region the lime is dissolved out of the sandstone, leaving an open warm soil, favorable to trees, while the same process of solution in the clayey chalk layers yields a sticky clay soil. The valley plains and uplands are surfaced with clayey mud. Hard stone suitable for road-building is entirely wanting, and the soil itself does not contain enough sand to form with the clay a compact embankment. The engineer may imagine what a task it is to maintain a roadway for army transport during heavy rains such as now are reported.

The entrenched character of the ravines and valleys is due in large part to the material in which they are cut. Where a stream has sunk down through a chalk layer, and come upon a bed of impervious clay, its valley widens faster than it deepens. The chalk, attacked along its lower edge, breaks off in steep faces and gives a abrupt rise from the valley-floor to a height of five or even thirty or forty feet or more. The profile then curves gently back to the surface of the plateau. Such a trench is invisible from a distance. The eye sweeps the landscape of a seemingly continuous plain, neither light nor color suggesting the sunken ground that must be crossed in an advance against the enemy. The chalk cliffs readily lend themselves to the excavation of natural and artificial caverns. In medieval times extensive catacombs were dug in them, and recently luxurious dug-outs or *tranchées*

placements for machine-guns have been excavated by the indefatigable Germans. The accidents of battle and of victory and the lines of final defence of the world against the German empire are determined by the deposits laid down beneath the ancient seas that spread the clay and chalk and sand, which are now the once fair land of northern France.

With this background of the battlefield in mind we may turn to consider the struggle of the ten days of the German advance. We may be sure that every attack has been made according to a preconceived plan, based upon a full knowledge of the character of the terrain and the opposing forces; and we may be equally sure that the resistance offered by the French and British has been proportioned to the force of the blow and the requirements of retreat with the least possible loss. The element of ignorance or surprise may be regarded as eliminated in this struggle between veteran strategists on the long contested battlefield.

The German attack was first reported as being directed against the British lines south-west and west of Cambrai. Shortly afterward we heard of fighting between St. Quentin and La Fere and of the German advance toward Ham. In the northern part of the field the severest fighting developed north-west of Bapaume, around the head of the Ancre valley. In the centre the attack was pressed against Peronne, and in the south an effort was made to cross the Somme in the vicinity of Ham and to advance to Nesle. Plainly the immediate object for which the different operations were scheduled was to drive the British into two positions from which retreat would be difficult, and to outflank the obstacles behind those two positions. In the north the triangular area isolated by the marshes of the Somme and the valley of the Ancre formed one pocket. In the south the great bend of the Somme between St. Quentin and Peronne formed another. In each case the marshy river-valleys offered obstacles to retreat, and the capture of Peronne split the retreating forces in the centre while seizing the principal crossing. It was, no doubt, defended with a tenacity that deprived the enemy of much of the expected fruits of his strategy, but it is probably a safe inference that the guns and prisoners lost were taken because of the natural difficulties opposed to retreat.

The position in which the British have elected to stand in the northern part of the field is entrenched by the valley of the Ancre. They did not attempt to hold the high ground south-west of Bapaume, from which in 1916 they forced the Germans only after four months fighting. They did not pause until they had placed between them and the enemy the deep trench that can be crossed only at enormous sacrifice. An advance farther north, in the vicinity of Arras, will be far less costly for either one of the opponents, and it is there, from Alette to Fampoux, that we now hear of repeated German attacks and stubborn British defence.

In the southern part of the field the French held firm along the Oise and its canals, from La Fere to Noyon. The line to which they fell back farther west lies along low hills that extend to Lassigny south-west of a little tributary of the Oise, and thence toward Montdidier along the line of the Lassigny-Montdidier railway. The Germans took and hold Montdidier, a station on one of the railroads connecting Amiens and Paris, but elsewhere they have not been able effectively to cross the little river Arve, which runs north-west to the Somme and, like the Ancre, offers a strong defensive position. It protects the Allies as far as Moreuil. At that point, however, their front turns north by east, and stretches across the angle between the Arve and the Somme, about 12 miles south-east of Amiens. Here we may expect the heaviest German attack, for it is the least defensible part of the Allied line and nearest to Amiens. Any advance here is sure, nevertheless, to cost the Germans very dearly, for, if the Allies retire farther, they will place themselves behind the Somme and the Arve and have the Germans in a narrow corner commanded by the heights beyond the rivers. And, even so, the Germans would not have reached Amiens, which lies farther down the Somme beyond the junction of the streams.

IDEAL SECTION ACROSS THE ANCRE TRENCH AND THE THIEPVAL-COMBES RIDGE

If the geographic conditions of the present situation have a preponderating value, we might infer that the Allies would seek to lead as many Germans as possible into the area south of the Somme; to allow them to accumulate there large supplies and many guns; to weaken them as much as possible; and then to cut them off by advances northward from La Fere and eastward toward Cambrai and Peronne. Such a manoeuvre would apply to the Germans their favorite play of the pincers.

Let the French and Americans advance northward from Noyons and La Fere toward Ham and St. Quentin. Let the British advance past Croisilles and Bapaume on Cambrai. And the Germans, if they save their army at all, must lose the larger part of it. So it looks to the man on the street.*

These geographic suggestions of the immediate battlefield are not favorable to the Germans. In sweeping into the region south of the Somme they have violated a military precept, in so far as they have left behind them an area across which it will be difficult to retreat. Ob-

*In the fighting of April 7-8, the Germans attacked the French south-east of La Fere, evidently to flank their position on the Oise and to prevent the counter blow that might be expected from this side.

viously, they estimate the chances of the necessity for a retreat as small, or they are led on by an objective that is worth the risk and that could not otherwise be obtained. Some have thought that objective is Paris, but to win Paris will defeat neither France nor Britain. Others suggest that the Allied line was here weakest, and that the general purpose is merely to break through, to separate the French and British, and bring about more open fighting. But a larger objective may well be attributed to the German high command. To separate the French and British, to take Amiens—these are but initial steps in the larger program. From Amiens the valley of the Somme offers a broad highway to the sea, which is distant but 35 miles in a straight line. The Germans have advanced 37 miles, and if now they can break through the British defence they may confidently hope to fight their way to the coast. The British army would then be shut up in a low corner of northern France, surrounded on the east and south by Germans, on the north and west by the Channel. Thus isolated they might be driven from the continent, and the invasion of England might become possible, even in spite of the British navy.

If this suggestion that England is Germany's objective seems far-fetched, impossible, we need to change our estimate of the purpose that dominates the Junker spirit. *Weltmacht oder Untergang* (world empire or destruction) is no idle boast, and thus far it has been made good throughout eastern Europe. No graver error could be made than to under-estimate the purpose, the audacity, the intelligence, or the power of the Enemy. We must match it and over-match it, individually and unitedly, confidently backing Foch, Haig, and Pershing, and the men behind them.

Chromite Deposits in Alaska

Deposits of chromite have been known in Alaska for a number of years, but they became of economic interest only in 1917, with the result that ore is commercially mined at one property. The chromite deposits of present economic interest, according to U. S. Geological Survey, are at the south-west end of Kenai peninsula, in two areas, one along the north shore of Port Chatham and the other at Red mountain, about 16 miles to the north-east. Both deposits are in altered peridotite, and, so far as known, these are the only bodies of peridotite in this vicinity. Exploration farther from the coast, in the mountains, may reveal others. Peridotite of the same kind also occurs in large and small masses at several other places in the area between the Yukon and Tanana rivers, and at Livengood, in which area is a deposit of chromite.

The chromite of south-western Kenai peninsula is in lens-shaped masses that range in thickness from a few inches to 20 ft. and that lie in attitudes from horizontal to vertical. None of the lenses appears to be more than 150 ft. long. The ore is not uniform. Some of it averages 50% chromic oxide, and some is a mixture of chromite and peridotite, the leanest part of which may

yield only 5 to 10% of chromic oxide. The deposit now being mined is on a spit at the south-east end of a peninsula known as Claim point, which projects south-eastward into Port Chatham. This peninsula measures about 4000 ft. from east to west and about 2200 ft. from north to south, and is joined to the mainland by a neck of land about 200 ft. wide. The rock is entirely peridotite. The known area covers about three-fifths of a square mile. The orebody is almost completely covered by water at high tide, so that mining must be done between low and half tide. The deposit is in a vertically placed lens, which has a length of about 100 ft. and a maximum width of 20 ft. About 800 tons of ore containing from 46 to 49% chromic oxide was mined in 1917, and about as much more remains in sight above half tide. Ultimately it will be necessary to work from a shaft or cofferdam.

Other lenses of high-grade ore, none more than three feet thick, occur in this vicinity, as well as a number of bodies of low-grade ore ranging in thickness from 5 to 20 ft. and varying in their content of chromic oxide from 5 to 15%. At one place on the north side of Claim point, near the crest of the peninsula, are four lodges that stand nearly vertical. These four bodies should produce, when concentrated, about 3000 tons of 50% ore. There should be available at Claim point at least 15,000 tons of chromite ore of a grade containing 50% of chromic oxide.

The peridotite at Red mountain is much larger than that at Claim point but is more difficult of access. The peridotite covers about three square miles and contains many stringers and lenses of chromite ore. The largest deposit observed was a lenticular body of high-grade ore not more than 75 ft. long, with a maximum thickness of eight feet at the centre containing about 1000 tons. There are many other smaller deposits and perhaps some as large or larger, all of which should yield at least as much chrome ore and possibly several times as much as the body at Claim point. These deposits are at an elevation of about 3000 ft. and at a minimum distance of six miles from tidewater. In winter the ore might be sledged to tidewater.

FUSED SILVER SULPHIDE, (Ag_2S), is sufficiently malleable at room temperatures to be rolled into strips, and at 200° C. it may be drawn into wires. According to George W. Vinal, a cold rolled strip has a large negative temperature coefficient of resistance, which is attributed to its possessing electrolytic conduction in addition to metallic conduction. A wire drawn at 200° C. is a metallic conductor only. The passage of an alternating current through a strip causes its resistance to increase, and a direct current causes a decrease. Hot drawn wires show no such effects. The a.c. and d.c. volt-ampere characteristics of strips resemble those of a pyro-electric conductor. Hot drawn wires behave as metallic conductors toward the direct current, the specific resistance at 2° C. being 17,300 microhm centimetres.

OF THE copper production of Peru, 96% is contributed by the Backus & Johnson and Cerro de Pasco mines.

Largest Electric Steel Furnace

The largest electric furnace in the world for making steel has now been successfully operating about one year at Pittsburgh. The illustration shows its general appearance. It was originally built to hold 20 tons at a charge, but it regularly makes 25 tons, and has produced as high as 30 tons at a time. It is the Heroult type of furnace, so called from the French designer. In the United States and Canada it has met with more success than any other form of electric steel furnace. There are now over 150 of them either operating or under contract in this country and in Canada. This particular furnace is in the Duquesne plant of the

ELECTRIC STEEL-FURNACE

Carnegie Steel Co., and is the only one of its size now running. There are, however, three more in process of being erected at Gary, Indiana, which will be operating soon. Six heats are made every 24 hours in this furnace, and the charge is hot metal from large basic open-hearth furnaces nearby. The steel that it yields is of the highest quality, and is used principally for small gun-forgings required by the U. S. government. Two other furnaces similar to this are now operating at the plant at the Illinois Steel Co., South Chicago, Illinois, and a third is being installed. With its two 15-ton furnaces, this is the largest electric steel plant in the world.

A METAL that will not shrink when it cools is desirable for making into patterns to use in place of wood. A completely non-shrinkable pattern-metal is unknown, but some alloys shrink less than others and one that is noted for this quality, and which is used largely for making white-metal patterns, is composed of zinc and tin in equal parts.

The Carolina Tin Deposits

The presence of cassiterite, oxide of tin, in North and South Carolina, at many places in the Kings Mountain and Lincolnton quadrangles, at one place near Gaffney, in the Gaffney quadrangle, and at one locality in the Gastonia quadrangle, has led to many attempts at mining. At the Ross mine, near Gaffney, placer mining was temporarily done at considerable profit. Practically all the work on cassiterite-bearing veins has been done at a loss, but this work has not been sufficiently conclusive to prove or disprove the value of some of the deposits. The cassiterite deposits have been found in a belt extending from a point two miles north-east of Grover, about parallel

with the general trend of the rock formations, through the town of Kings Mountain, and north-eastward to Beavertown creek, six miles from Lincolnton. The tin deposits occur in pegmatite masses within Archean rocks, either the Roan gneiss, or the Carolina gneiss along or near its contact with the Roan gneiss. The rocks enclosing the pegmatite are hornblende schist, hornblende gneiss, diorite, mica schist, and mica gneiss, with or without accessory garnet and kyanite. These formations have steep dips along the tin belt. The pegmatite occurs in sheets and lens-shaped bodies cutting the gneisses and schists. Some of the pegmatite masses are conformable with the structure of the enclosing schists, but others cut across the schist layers with various dips and

strikes. The masses range from less than an inch to 100 feet wide and from a few inches to probably more than half a mile in length.

SECONDARY ENRICHMENT, in distinct zones, of lead, zinc, and silver, is noted by Fred. A. Hale Jr. in the Yellow Pine mining district, Clark county, Nevada. The zinc minerals, being more soluble, migrated farthest, while the lead accumulated nearer the surface. The silver content of the ore shows a marked increase with depth for a distance of 120 ft., from which point it decreases to its minimum at 700 feet.

LICENSES are now required for export shipments of wire-rope. This applies to iron and steel wire-rope, cable and strands consisting of six or more wires, whether or not the wires are painted, galvanized, or coated in any way. Improper classification of material in order that it may be exported without a license subjects the exporter to severe penalties.

Sacramento Hill Disseminated Copper Deposit—I

By COURTENAY DE KALB

INTRODUCTION. The world at large has not yet been impressed with the significance of the name of Sacramento hill. Utah Copper, the first great 'porphyry' mine, the one that established a new system of exploitation and that opened the way to the profitable treatment of 1.2% copper ore, is a name known to every miner in

last four years, after it had become apparent that a valuable orebody actually lay within reach. Even if there were no Copper Queen mine as a wealthy neighbor to Sacramento hill the orebody now disclosed would afford ample warrant for a great independent operation, yet it is almost certain that no economic geologist would have

SACRAMENTO HILL, BISBEE, ARIZONA; LIMITS OF OREBODY FLAGGED ON SURFACE

America and to millions who are not miners; 'Nevada Con.', 'Ray', 'Chino', 'Miami', 'Inspiration', are familiar because they have been prominent as bases for independent financing and stock speculation, and also because they were brought forward in the bright aurora when the wonder of monstrous new mines of low-grade copper still made a lively appeal to the imagination. Men are growing used to them now, and the development of millions of tons of 1.70% copper ore in a rugged hill of hard brownish-red nondescript rock produces no sensation. Sacramento hill has been quietly investigated for about nine years by the Copper Queen Consolidated Mining Co., now merged into the Phelps Dodge Corporation. The more active work, however, has been confined to the

ventured to recommend the exploration of this unpromising pile of rock except for the evidence of neglected possibilities in the great granite-porphyry stock that had accumulated through years of mining upon the orebodies in close proximity. It is too late now for visitors to study the rugged cap-rock; it has all been blasted and scattered, and will soon be no more than a waste-dump in a distant canyon. Those who have kept in touch with the Copper Queen for the last 20 years, however, will remember the peculiar knotted mass of hard brown rock standing prominently in the wide arroyo, in the position of the proscenium of a Greek theatre with reference to the shafts of the Czar, Holbrook, Spray, Irish Mag, Sacramento, Oliver, Hoatson, and Junction mines, gathered in a wide

are round about it. The interest at that time was fixed upon this assembled group of giants; now something has happened in the centre of the stage.

In one of the accompanying illustrations, taken from the Gardner shaft, Sacramento hill is shown almost as it stood at the beginning, except that it is scarred by roadways over which the drilling machines have been dragged, and that it shows the dump of a prospect-shaft. It is also flagged to reveal at a glance the projection of the developed low-grade orebody in outline upon the surface. The Dividend fault passes just beyond the rough mass of the hill, and on the other side of it is a range of mountains against the sky-line composed of disturbed and faulted beds of Cretaceous age. The line of sight is toward the north-east, and the Dividend fault strikes north-west. Thus the illustration affords a broadside view of the chief line of structural weakness in the district. The photographs fail to bring out the detail of the peculiarly irregular character of the cap-rock, but it is recognizable as indicative of something different from an intrusive igneous rock or a lava-flow; on close view it proves to be fragmental, and composed of many distinct kinds of rock, somewhat agglomerated, highly altered, decomposed, varying in color from gray to bright brownish-red, considerably glazed with the 'desert-varnish', and having a few areas of no great size, on protected faces and in crevices, painted a dull green with copper carbonate. Any old prospector in Arizona knows a dozen places that look more attractive. A good many that were far more brilliant have been tested and found wanting; some of them may have been 'turned down' after a too faint-hearted exploration. The first efforts to ascertain what might lie hidden in Sacramento hill would have exhausted the resources of the average development company without yielding definite encouragement, as will be noted in the sequel.

When one looks over the busy Warren district with its numerous shafts and sees the train-loads of ore hurrying to the smelters at Douglas it is hard to realize the struggles and doubts and fears of the early days, or the narrow chances by which these mines were once saved from abandonment. The Queen company and the Atlanta company, working side by side, had exhausted all the ore in sight, and extensive exploration had failed to lead to new discoveries. Dr. James Douglas had originally taken an option on the Atlanta for \$25,000, but failed to finance it; finally he was called upon, in 1881, by Mr. James, of Phelps, Dodge & Co., to report upon this identical claim, which later had been offered to that firm. Dr. Douglas reported upon the progress of work on the Queen as well as the Atlanta, both of which were then producing. Sinking on the Atlanta had extended to a depth of 100 ft.; the orebody was near the boundary line of the claim and would probably enter the Queen claim if it held out, and there was no ore of any value on the surface of the Atlanta. The uncertainties, including the danger of legal complications in case the orebody should enter the Queen ground, led him to advise his client that "the

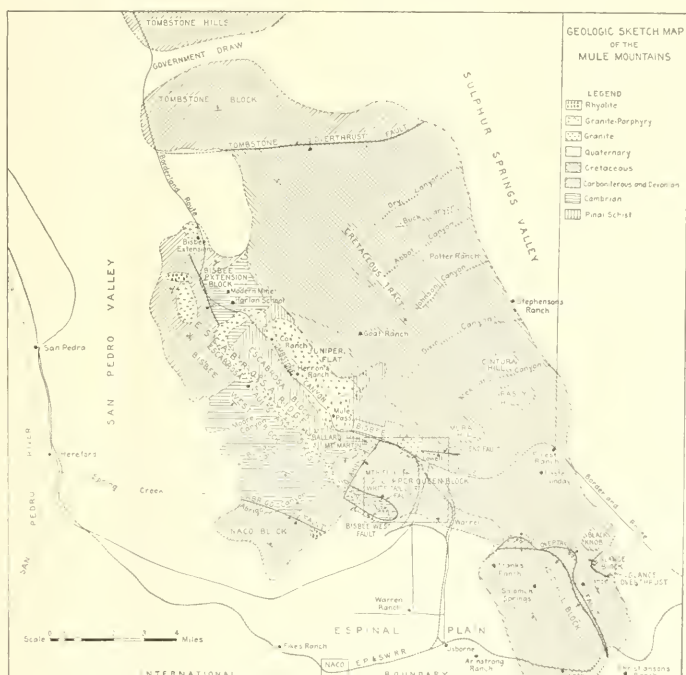

risks were too great to be taken by a purchaser who was not able and prepared to lose all that he had invested." It was decided to take the chance, and an adit was driven parallel with the side-line of the Queen, but it proved to be too low to strike the Queen orebody, and too high to intersect the Atlanta. Dr. Douglas records also that he "sank on one of the small bunches of ore that cropped out on the east side of the claim. It twisted in and out in descending, but apparently led to nothing of consequence, and was abandoned. Had it been followed 200 ft. it would have led us into the big orebody two years in advance of its actual discovery." Both the Queen and the Atlanta passed through vicissitudes, the heavier burdens falling upon the Atlanta, which was owned by Phelps, Dodge & Co. Its only asset, after several years of work, was a sum of \$4000 paid by Mr. Simsbury of transcontinental stage-coach fame for permission to mine lead carbonate ores on the Atlanta claim to be shipped to his smelter at Benson. Dr. Douglas, in his own story of the mine, writes: "The spring of 1884 was a critical period in the history of Bisbee. The big orebody on which the Copper Queen had been working since 1880 had pinched out clean before the incline sunk on it had reached the fourth level. The Queen had run a drift west into the King, and was drifting east along our side-line in search for another orebody. Mr. Williams was opposed to the opinion of a San Francisco attorney whom Mr. Martin (of Martin & Ballard) had sent down to advise whether the law of the apex applied, and who had advised him that under the Richmond-Eureka decision the limestones between the porphyry contact and the outcrop on the top of the Queen hill might be considered a vein or lead under the law, being a mineralized zone. The Queen also had employed Mr. Price, of San Francisco, to advise them as an expert, and he pronounced only 90 days' ore in sight, and could not tell them where to look for more. Results have since proved that there was not more than 90 days' ore in sight. Meanwhile Mr. James and Mr. Dodge had become thoroughly disheartened, having spent some \$80,000 and over two years on exploration that had not yielded a carload of ore. There was a meeting with me in New York. The only underground trail I could recommend as worth following was a narrow vein of ore crossing our line from the big Queen orebody. Mr. Williams considered that he had no right to follow it. We could reach it only by sinking from the surface and drifting, and to do so would cost, I estimated, \$15,000. So the last \$15,000 to be dropped into the mine was, with much misgiving, put at my disposal, and John Prout and I selected the site where the shaft was to be sunk. * * * The foot of the Queen incline, which coincided with the bottom of the original Queen orebody, had nearly reached the side-line of the claim, and therefore a drift easterly along the side-line in hard limestone was the exploratory work undertaken by the Queen—a long drift having been previously run to the West without encountering any ore. Meanwhile our Atlanta company was sinking its shaft in barren limestone a little to the

south of the point toward which the Queen drift was directed. Thus, final pieces of exploratory work were under way, prior to the abandonment of their property by both companies, when, almost at the same time, each of them struck a new orebody, which appeared to be dipping north-west, or in a direction the reverse of that of the body originally discovered. The two companies then

presently give way to sulphide. As Dr. Douglas wrote, in some reminiscences of Arizona mining in 1909,* "We all imagined, in our shortsightedness, that the day of doom for the copper interests of southern Arizona would date from the transition from oxidized to sulphide ore. It was not until all the richer carbonate ores had been wasted by being largely converted into slags that the companies

CROSS-SECTION THROUGH ORE DEPOSITS AT BISBEE, INCLUDING SACRAMENTO HILL

GEOLOGICAL SKETCH-MAP OF THE WARREN DISTRICT, ARIZONA

wisely decided to consolidate on equitable terms, rather than waste their funds in obtaining a legal interpretation of an even more complicated problem than that involved in the Richmond-Eureka 'apex' case."

The continued development of chamber after chamber of valuable oxidized copper ore did not, however, establish confidence for the future. The life of the mines was regarded as doubtful; it was argued, not only at Bisbee, but also at Clifton and Globe, that the oxidized ore must

recognized that their salvation depended upon securing sulphide ores, upon making metallic copper through the medium of matte, and throwing away less copper in the slags." Thus the sulphides, when first beginning to appear, were regarded as a nuisance; today the Warren district produces chiefly sulphide ores, and the advance in metallurgy has made it possible to treat the low-grade

*"Conservation of Natural Resources", Trans. A. I. M. E. Vol. XL, p. 422.

chalcocite deposits in Sacramento hill that average only 1.70% copper. This has added perhaps 20,000,000 tons to the resources of milling and smelting ore available at the Copper Queen mines, in addition to which a few million tons of ore averaging slightly lower than 1% copper may be amenable to treatment by heap-leaching, giving a return of 75 to 80% of the metal content.

superintendent, drove many hundreds of feet of drifts within the porphyry stock, but unfortunately on a horizon below that in which lay the ore. It was only when the 200-ft. level from the Holbrook was driven that commercial ore was discovered beyond the limestone contact. As disclosed later, an extension from the 200-ft. level of the Holbrook shaft, driven in a south-easterly direction

PLAN AND ELEVATION OF SAMPLE-SPLITTER

DEVELOPMENT. The uninteresting mass of Sacramento hill lay untouched for decades after Bisbee had attained worldwide fame as a copper-producer. Nevertheless, Dr. Douglas always expressed faith in the existence of ore under this rugged pile of rock, and instructed his son, Walter Douglas, when he became superintendent of the Copper Queen in 1899, to acquire at any reasonable cost such claims as were not owned by the company in the neighborhood of Sacramento hill. Mr. Douglas, while

for 150 ft., would have entered the ore-zone had the drift been prolonged 450 ft. farther, but the course was changed, bearing more to the east, and this ultimately proved to be nearly tangential to the orebody as now developed. After driving 300 ft., work was stopped in June 1908, and was not resumed until July 1909. The Sacramento adit was started from the northern flank of the hill in January 1910 and penetrated the top of the east ore-zone at a distance of 700 ft. from the portal.

The work was concluded in August of that year, and it had given encouragement for the continuance of the earlier drift. This skirted the west orebody for some distance, but without affording indications of positive value. At 1000 ft. the drift was turned sharply to the south. Ore was found within 80 ft., in July 1911. Another cross-cut, 550 ft. from the point of departure, had been turned south-westerly. This passed good ore on the way, and cut workable sulphides only after having penetrated 125 ft. beyond the ore-zone as now delimited. That point was reached in June 1911. A station was cut in the Sacramento shaft between the adit-level and the 400-ft. level, from which a drift northward traversed 210 ft. of porphyry averaging 2.21% copper. The cross-cut from the No. 277 drift, leading from the Holbrook workings, had passed through 25 ft. of material that averaged 3.8% copper. Up to February 1913 drifts, cross-cuts, and raises, aggregating 19,604 ft., had developed about 500,000 tons of ore, including a considerable tonnage averaging 3.53% copper.

Development by churn-drills was then undertaken under the general supervision of Arthur Notman, who is now assistant superintendent of the Copper Queen mines. A line of prospect-holes was first drilled to determine in a general way the extent of the orebodies. The area to be explored was roughly 3000 ft. long by 1400 ft. wide. Subsequently the larger part of the hill was tested by drill-holes at the corners of 200-ft. squares, and as the work proceeded intermediate holes were put down 100 ft. apart. Owing to the difficult topography it was not possible to space the holes evenly over the entire area, but to a large extent the ruggedness of the ground was overcome by building roads over the steeper portions almost to the summit of the hill. These roads were only 9 ft. wide, and the grades were often as much as 30%, the drills being drawn up by cables wound on the drum of the machine. The roads followed contours, as far as possible, with inclines from one level to another, and involved a total cost of \$22,065, or \$1.46 per foot, for the initial testing, and, as figured against 60,000 ft. of drill-holes, this item amounted to 37c. per foot of hole. In the earlier part of the campaign the cost of drilling, exclusive of the purchase price of equipment, is stated by Mr. Notman to have been \$2.70 per foot, of which \$1.99 was for labor and supplies, and 71c. for road-building. This figure was based on 8000 ft. of drill-hole. Drilling was done by a Star steam-machine, and by four Armstrong electric drills. Details of the performance of the steam and electric drills are given by Mr. Notman; he concluded that electric drills could be operated at a trifle less cost than steam-drills. The odds were nearly even, however, and after the first active campaign was ended the work was continued with a heavier Star steam-drill, which is now busy on the deeper eastern extension of the orebody beyond the area already proved. Three shifts are operated, and the records show an average of about 60 ft. of hole drilled per 24 hours. In the softer ground 100 ft.

per day is not uncommon, and an advance of 147 ft. in one day has been made. The holes are started with a diameter of 10 in., and usually end with a 6-in. casing, although some of the deeper holes are finished with a diameter of 4 in. The crew consists of a driller, a helper, and a sampler. The usual methods of sampling have been employed, the sludge from the bucket being run through a 'splitter', delivering $\frac{1}{16}$ th to the drying-pan. Accuracy in the design of the splitter is an important factor, and the alternately wide and narrow splits in the Bisbee design are worth noting. This arrangement has been found to give more uniform results, and to break up the tendency to concentration when the pulp washes through the sampler. As the construction of such a piece of apparatus, though seemingly simple, is in reality a careful tinsmith's job, and is likely to go wrong in the hands of a workman who has never seen one before, the detailed drawing given herewith may prove useful. The split-box is made of galvanized iron, No. 16 Brown & Sharpe gauge. The dry weight of the sample taken with this apparatus in the Sacramento hill operation was about 10 lb. per foot, a 50-lb. sample representing five feet of hole. The assay cost was 3.5c. per foot, which is included in the general expense of \$1.43; the initial cost of the drilling machines and other equipment, distributed to 60,000 ft. of bore, averaged 17.2c.; and the total cost came to \$1.97 per foot. The checking of the drill-samples by raises, in which channel-samples were taken, has afforded remarkably accordant results. As a fair example, a raise sampled by channels cut every 5 ft., at a distance of $2\frac{1}{2}$ ft. from the original drill-hole, and yielding samples averaging 8 lb. per foot, gave an average assay-value of 3.79% copper against 3.8% from the drill-samples.

The deposit consists of two parts separated by a zone of feebly mineralized ground about 400 ft. wide. The two orebodies lie in the same general direction, and a single axial line bearing N. 80° W. will cut approximately through the centre of both. Therefore they are named respectively the West and the East orebody. In the West orebody more than 7,000,000 tons of mill-ore, averaging in excess of 2% copper, has been developed, and 1,000,000 tons of +0.7% suitable for leaching in heaps. The East orebody, still in the development stage, has more than 10,000,000 tons in sight, but the average grade is considerably lower. Drill-testing is still in progress at the east end, and will be continued with one drill until the entire area has been covered, which seems to afford possibilities of a large addition to the ore-reserves.

(To be Continued)

THE SCHOOL OF MINES of Saint Etienne, in France, which had been closed after the outbreak of war, has just re-opened, with 26 students who had been retired from service on account of serious wounds, together with others between the ages of 15 and 19 years. An innovation in the history of this ancient technical institution is the admission of women to the courses leading to the degree of mining engineer.

†Trans. A. I. M. E. Vol. LII, Sept. 1915

Smelting Changes to Conserve Zinc

By WOOLSEY McC. JOHNSON

*In the retort-zinc works a charge of roasted zinc ore with a side mixture of carbonates and silicates, analyzing on the average 50% zinc, is mixed with 55% or more by weight of a mixture of coal and coke analyzing 60 to 70% fixed carbon. The ore is of varying fineness and the coal and coke are usually crushed in a semi-moist condition through a $\frac{3}{8}$ -in. screen. With ore of a slaggy nature, the proportion of coal is increased, even to an equal weight with the ore. The average charge per retort for a monthly run of a plant on ore, as distinguished from retorts on blue-powder, ladle-skimmings, and other middle products, runs from 60 to 66 lb., with a mean of 63 lb. for the South-west, with standard retorts $8\frac{1}{2}$ in. diameter and 50 in. long, inside dimensions, when using roasted sulphide ores. Conditions will change these figures, but 40 lb. of ore per cubic foot of retort-space is, I believe, an average in the better-operated plants. Since the rise in the price of spelter, the tendency has been to over-charge. To remove the slag that is formed when retorts are over-charged, extra men are put on to 'gum-chisel' the retorts to prevent 'set' furnaces and 'butchered retorts'. Taking the above conditions as premises, four to six times the amount of coal is necessary for the reduction, as shown by the fact that the residues analyze as high as 35% fixed carbon. There are good reasons why this excess of fixed carbon must be used. These may be enumerated as follows:

(1) High reducing power, especially at the end of the shift, to reduce any carbon di-oxide to monoxide, and cause good condensation of the vapor. It is well known that CO_2 , if formed in the retort, oxidizes the zinc-vapor at lower temperatures, and is the cause of the formation of an excessive amount of blue-powder.

(2) Heat conductivity as high as possible, so as to permit the heat, as soon as it permeates the walls of the retort, to flow to the inside of the charge in order that as uniform a temperature as possible may be attained in the retort. For this reason large pieces of coal, ore, and coke are charged, since fine material is a poor conductor of heat.

(3) Porosity; if the charge be too dense, the back pressure of the gases produced is so great that the reduction is hindered. Moreover, porosity allows secondary gaseous reduction to proceed:

(4) The charge must leave a residue that is substantially non-slugging in character. Since carbon is in-

fusible, this can be attained by having sufficient fine carbon present in the charge, so as to leave particles of carbon in the residue.

In my work on electric smelting where only 12% of coal was added, it was shown to be possible, operating on a fairly large scale, namely, 1 ton of charge per day, to reduce zinc ore successfully with only the theoretical amount of coal. This points the way for certain improvements in the reduction of zinc ore in the retort. Coal-dust firing, used successfully in the cement and smelting industry, was taken as a pattern. In this, the almost instantaneous oxidation of carbon is attained by the use of coal in the form of dust. Since any reduction process is likewise an oxidation process, it is not fanciful to regard zinc reduction as an oxidation of the 'charge'-coal. Tests were made, grinding both the zinc ore and the coal to 80-mesh and finer. These fine mixes were worked off in a crucible or in a retort, and while they produced certain advantages, they also showed conclusively that the fine charge had the disadvantage of being so dense as to hold back the zinc-vapor and gases, and so to diminish the speed of the reaction. In the conventional furnace, large pieces of coke are put in to 'ventilate the charge.' Accordingly, an addition was made of broom-straw. These yield a carbonized skeleton that is preserved during the retorting operation and provide a path for the gases, so that they have a way of exit. Moreover, these carbonized skeletons, or eductors, are an ashless and active form of carbon, and thereby reduce the carbon di-oxide to carbon monoxide. Since the flow of the gases naturally takes to these eductors, this super-reduction is efficient in improving condensation. In these tests, the percentage of reducing material was gradually decreased from 60 to 50, 40, 30, 25, and 20%, successively. It was found that with complete reduction (residues containing 2 to 0.5% Zn) there was no slugging of the ore, provided the proportion of coal was left above 20%, unless the ore was especially slaggy. For instance, using an ore with Zn 22%, Fe 33, S 3.8, SiO_2 6.4, CaO and alkali 4%, with 20% anthracite, there was slight fritting, but none with 25% coal. In general, with reducing coal analyzing fixed carbon 67%, volatile matter 26.6, ash 12.4, and an ore analyzing Zn 43.5%, Fe 7.10, CaO 40, or more, there is no trouble in getting residues that contain absolutely no 'gum' or slag, and analyzing in zinc 2.1, 0.6, 2.9, 2.1, 1.8, and 0.5%. The ore-charge per retort was thus raised to 100 lb., and the coal reduced to 30% or lower. The reason is that the charge is highly reductive, because of its fineness and the peculiar way it is 'ventilated', and since the immense number of fine particles of carbon left at the end hold up the slag-making particles and any

*Abstract: 'Fine Grinding and Porous Briquetting of the Zinc-Charge', A. I. M. E., February meeting.

iron sulphides, little gum is formed, and, if formed, it does not touch the retort-walls. Instead of the carbon particles passing through the process without oxidation, many of them $\frac{3}{8}$ in. diameter, and without performing any useful purpose, the surface of the particles is increased 40 to 50-fold. Holding to the original simile of coal-dust firing and remembering that in zinc reduction two solid reagents must be made to combine, the great theoretical advantage of a finely-ground porous charge is evident. For practical working, however, a charge must be a fair conductor of heat, for zinc reduction is heat-absorbing. This fineness of the charge, while it certainly promotes the reduction if properly 'ventilated', makes the charge a poor conductor of heat, which is a decided disadvantage in practical retorting. This poor conductivity is overcome by briquetting, which lessens the volume, but at an expense of \$1.50 per ton of ore. Since the density of coal is less than half that of the ore, the reduction of the percentage of coal from 60 to 30 or less increases weight of zinc ore per cubic foot from 42 to 63 lb., or increases the charge per retort from 67 to 100 pounds.

Assuming a cost of \$17 per ton of ore for smelting under present conditions, the fine grinding, ventilating, and briquetting permits a reduction in cost, by means of increased charging, of \$5.67. The reduction in charge-coal cuts the cost of coal from \$2 to \$1.20. There would be a reduction in furnace labor and a reduction in retort consumption because the charge gives a residue that blows out clean. I believe that the recovery will be increased because of low residues and decreased retort-consumption: perhaps this saving will amount to \$3. The credits thus total \$10.97 while the debit is \$1.50; or a total net saving of \$9.47 is possible. Concluding, it may be stated that the present method of using a 400% excess of reducing-coal is unscientific for the reason that such an overwhelming excess is not needed. Whether the reduction be done by solid carbon or by carbon monoxide, coal that passes through the process to a large extent in large particles, not acted on at all, serves no useful purpose except to make the charge heat-conductive. Fine grinding of coal and ore, unless it be flotation concentrate, utilizes the efficiency of the coal to its maximum, and produces collateral advantages. Kernel-briquetting gives the necessary heat conductivity. The commercialization of this proposal would, in my judgment, effect an important saving in coal, zinc, and labor, which would benefit the Nation as a practical application of sound principles of conservation.

MARGIN SPELTER, according to the classification of the American Society for Testing Materials, consists of five grades, namely, No. 1 or high grade, No. 2 or intermediate, No. 3 or brass special, No. 4 or selected, and No. 5 or prime Western. No. 1 must not contain over 0.07% Pb, 0.03% Fe, 0.07% Cd, and must be free from Al. The sum of lead, iron, and cadmium must not exceed 0.1%. With No. 2 the maxima are raised to 0.2% Pb, 0.03% Fe, and 0.5% Cd, the sum total not exceeding 0.5%. In No. 3 the impurities may reach 0.6% Pb, 0.03% Fe, and 0.5%

Cd, with a total under 1%. No. 4 may contain 0.8% Pb, 0.04% Fe, and 0.75% Cd, with a total not over 1.25%. For No. 5 the tolerance is 1.6% Pb and 0.08% Fe.

Preferred War-Time Industries

It would be impossible to arrange a list of essential industries for the conduct of the War in the order of their relative importance. Preferential treatment according to a scale of priority would soon cause a smash. The best that can be done is to separate the industries that contribute to imperative and immediate needs from those that do not so contribute. This has been done by the War Industries Board, the object being to accord the preferred list priority of service as regards transportation and fuel. The following is the official register, alphabetically arranged: Plants engaged exclusively in manufacturing aircraft or supplies and equipment, ammunition for the United States and the Allies, Army and Navy cantonments and camps, small arms, chemicals, coke, electrical equipment, electrodes, explosives, farm implements, ferro alloys, fertilizers, fire-brick, food for human consumption, food-containers, gas, gas-producing machinery, guns, hemp, jute and cotton bags, insecticides, fungicides, iron and steel (blast-furnaces and foundries), laundries, machine tools, mines, mining tools and equipment, newspapers and periodicals, oil, refineries (mineral and vegetable), oil-well equipment, public institutions and public buildings, public utilities, railways, railway equipment and supplies, refrigeration, seeds (except flower seeds), bunker coal (not including pleasure craft), ships, ship supplies and equipment, soap, steel plants and rolling-mills, tanning plants (except for patent leather), tanning extracts, tin-plate, twine (binder) and rope, wire-rope and rope wire.

MOLYBDENUM STEEL is used for the rifled liners or tubes of guns, for armor-plate, armor-piercing shells, permanent magnets, safes and bank vaults, lamp filaments, self-hardening and high-speed machine tools. Molybdenum steel, says Ernest R. Woakes, compares favorably with tungsten steel and does not require such a high temperature for hardening. Salts of molybdenum are used in pigments and for producing a yellow glaze on porcelain. The ammonium salt is largely used as a reagent for the estimation or detection of phosphorus. It is also said that a compound of molybdenum is used as a preservative for cordite when stored in hot climates. Steel-makers generally reckon that it requires two and half times as much tungsten as it does molybdenum to produce a steel that will give approximately similar results.

AUSTRALIA will have spent, by September next, the sum of £233,000,000 (\$1,118,000,000) on the War, according to the Commonwealth Treasurer. Of this £100,000,000 (\$480,000,000) had been raised in Australia, the balance in England. This is equal to \$96 per head. The 3 war loan, of £40,000,000, is now being subscribed to.

REVIEW OF MINING

NEW YORK

The New War Loan.—Mexico.—American Metal Co.

The financial topic of the week has been the terms of the new War Loan. The smallness of the amount asked came as a surprise, but the terms were regarded as favorable, especially with reference to maturing. The comparative shortness of the term will do much to prevent market depreciation, such as has been evidenced with previous war issues. Liberty 4s have apparently not yet touched bottom, and their inability to respond to the fact that they would be convertible into the new issue at par is explicable by the fact that conversion would insure the new interest rate, but that the maturity feature would be retained. New York is allotted about \$1,500,000,000 in the new loan. Local organization is complete and comprehensive. Much has been learned by the floating of previous loans and a general and systematic canvass is to take place. Apart from this it is realized that many of the people have been educated in thrift by the possession of a Liberty Bond and are now anxious to add to their reserves; a closer realization of the War will make others respond; and the more favorable terms, which will tend to prevent undue market depreciation during the life of the loan, will satisfy those whose circumstances make it impossible to invest in any security whatsoever without paying preliminary regard to cash value at any time when they may be obliged to realize. There is a general impression that the loan will be largely over-subscribed. In some quarters it is expected that the record—the English war loan of a year ago, amounting to \$4,900,000,000—will be eclipsed. Seventeen towns and districts in New York State over-subscribed their quotas before the official date. Optimistic forecasts are to be condemned when they spring from a determination to 'let George do it.' In the present instance there is a widespread conviction that the Great Cause can be helped by active participation, and this augurs success for the new issue.

The Mexican situation is being viewed with increasing optimism. Reports of the re-opening of mines and gradual resumption of mining and milling operations are being received. Communication is improving, and letters from the South come through fairly promptly. The recent Mexican government decree exempting mining machinery from all import duty will encourage the industry, at the same time proffer a field for expansion for American mining machinery manufacturers whose export trade may have been curtailed by the recent shipping regulations. Another matter for favorable comment is that the Mexican government has seen fit to modify the decree of September last with reference to importation and exportation of precious metals. The present restrictions are drastic enough, but satisfaction is expressed that the 'thin edge of the wedge' of disapproval has been applied with success. After stating that permission for the export of bullion must in all cases be obtained from the proper authorities, the new decree ratifies the clause in the previous decree with reference to the exportation of ores and concentrates; it prohibits the exportation of gold bullion of local production, of all gold coin, and domestic silver coin; it permits the exportation of Mexican silver currency provided that an equal value of gold bullion is imported for

Government minting; and it makes the importation of gold free from consular fees and other charges.

The authorities at Washington have given passports to one of the vice-presidents and the treasurer of the American Metal Co. to permit them to go to Switzerland for the ostensible purpose of arranging for the elimination of German control in the company's Mexican interests. Prior to the declaration of War this company was admittedly German, and since March 1917 it has been under surveillance by the United States authorities. In October last the Custodian of Alien Property seized some of the assets of the company.

LEADVILLE, COLORADO

Labor Shortage.—Manganese Reserves.—Gold in Sugar Loaf.—Diamond-Drilling.—Lease Notes.

Operations in this district are considerably hindered by the most acute labor shortage experienced in many years. With the beginning of trouble culminating in a strike last year, many of the best miners left the district and have not returned. Others are leaving continually, and apparently

MAP SHOWING SITUATION OF LEADVILLE AND CONTIGUOUS DISTRICTS.

are securing in other districts better working conditions or higher wages than can be obtained here. For the first time Mexican labor has entered the mines at Leadville. The Yak is the only important company that has yet accepted Mexicans, but it is possible that others will be forced to do so unless conditions improve. Mexicans have almost completely substituted the Austrians and Slavs at the Arkansas Valley plant of the A. S. & R. Co.

In a recent report of the U. S. Geological Survey, in which the manganese resources of the Western States are listed, the Leadville district is credited with having 13 deposits with possible reserves of 1,500,000 tons. The average grade is 23% Mn with 27% Fe and 12% SiO₂.

The Bohn property on Carbonate hill is credited with being the producer of the best manganese ore now being extracted in Colorado. The product now being shipped carries from 35 to 38% Mn. An immense body of the ore has been blocked out.

Gold has just been discovered for the first time in the Sugar Loaf territory through development that is being carried on at the old Bartlett mine, for many years a large producer of high-grade silver ore. A 5 to 12-in. vein was cut in one of the main silver shoots, assaying from 2 to 26

oz. gold per ton. Although the Sugar Loaf area is one of the oldest parts of the district, this discovery is the first intimation that it contained any gold ore. Extensive development has been completed through the Bartlett, Dinero, and Virginus mines, where the richest silver veins here were opened, but in all the ore extracted not a trace of gold was found. Development at the Bartlett requires constant attention from local mining men, who are eager to learn whether the discovery is just an isolated fissure or a feeder to a well defined orebody. The present extent of the gold vein has little importance in itself, but the fact that, after years of continuous operations in many properties, gold ore carrying as high as 26 oz. has been discovered, is regarded as holding great possibilities. Both the Bartlett and the Dinero are shipping a regular tonnage of rich silver ore, some of the product running 3000 oz. per ton. This production, together with the gold strike, has renewed interest in the Sugar Loaf area, and a great deal of new development is expected to start this month.

Lessees at the Sunflower shaft of the Nisl Prius in Iowa gulch have another important discovery in a large body of lead-silver ore. This was found in one of the big manganese stopes, which had been partly worked out and temporarily abandoned, and has developed into a continuous shoot 8 ft. wide and 15 ft. high. The first assays gave 15% lead and 11 oz. silver, but more recent tests show 23% lead and as high as 35 oz. silver per ton. The ore is a yellow ochre, and was exposed by the caving of a thick seam of giant clay, up to which the manganese had been extracted, leaving it as the apparent end of the ore.

The manager of the Dold Mining Co., C. J. Dold, has resumed sinking the Northern shaft and plans to continue this work until the parting quartzite has been penetrated and the second contact reached. The Northern is now 645 ft. deep, the bottom being in quartzite. Another 50 ft. is expected to put the shaft into the contact. Deeper work will be determined by conditions here. In the Coronado property adjoining the Northern, large bodies of lead-silver sulphides were encountered in the second contact, and there is every reason to believe that these ore-shoots will be found extending into the Dold ground. For several months, the Northern has been a heavy producer of manganese, and several of the largest deposits opened in the district are now being developed. The Dold company proposes to re-open the old Newell shaft, west of the Northern, for handling the manganese.

The manager of the Matchless Mining & Leasing Co., Edward Huter, has started a diamond-drill in the bottom of the Matchless No. 5 shaft. Sinking was started recently in the Matchless shaft in an effort to penetrate the parting quartzite, but it never emerged from this formation. The extremely high cost of sinking caused the management to stop, and determine possibilities by drilling.

The old Keen shaft on Yankee hill has been re-opened by Austin Blakey Sr. and J. P. Hepburn. An electric hoist is being installed, and the shaft will be re-timbered to the bottom, 335 ft. The Keen lies directly on the well-defined ore-belt that traverses the northern extensions of Yankee hill, and opened in the Ponsardin and Hayden shafts. These properties are both heavy producers of lead, silver, and zinc ores.

Engineers from the Western Chemical Co. at Denver are making an examination of the Greenback property in Graham park. The work is in charge of Mr. McDaniel, well-known in Colorado. Large deposits of pyrite of high sulphur content have been opened in the Greenback, and the sale of the property to the Denver company is expected when the examination has been completed. The property is now owned by Patrick Mulrooney, and was unwatred some time ago.

VICTORIA, BRITISH COLUMBIA

Legislation Affecting Working Hours; Views of Those Interested.

A general eight-hour day for men employed in and around the metal and coal mines of British Columbia seems assured. A bill providing for such an innovation has been placed before the legislature of the Province by the Hon. Wm. Sloan, Minister of Mines, at the session now in progress. While it has not yet passed the House, indications are that it will become law at an early date.

In one of these measures the Metalliferous Mines Inspection Act is amended to read that the working day of those employed underground shall count from the time they leave the surface until their return to the surface; and that those employed on the surface at or about a metalliferous mine shall not be required to work for a longer period than eight in any twenty-four hours.

An amendment is also proposed to the Coal Mines Regulation Act giving the men employed on the surface at or about a coal mine the same working day as that given his fellow, whose work takes him underground, by the British Columbian Legislature in 1905. Ever since that year the coal miner of this Province has had the eight-hour day; that is, it has not been permitted that his employers keep him in the mine for a longer consecutive period, his working day counting from the time he left the surface and not from the time he picked up his tools at the working face.

Still another legislative proposal of similar character has been submitted by the Attorney-General. It provides for an eight-hour working day in and around smelters. Those employed within these plants, being more affected by the fumes, have had this concession. The Act under consideration would give the same to those otherwise engaged; in fact would make the rule generally applicable to all, with few exceptions, on the payrolls of smelting companies.

The Minister of Mines argues that these steps have been demanded by miners and smelter-men for years, that failure to take definite action has caused constant friction between employer and employee, and that the establishment of the principle of an eight-hour day for such industries will have a salutary effect. It is his opinion that under such a working arrangement the men will be more satisfied, and there will be less reason for industrial trouble. In this connection he points to the strikes in British Columbia in 1917: at Fernie, where the coal mines were closed for several months; at Rossland, where a lockout was declared by the Canadian Consolidated Mining & Smelting Co., when the men threatened to strike; and at the Trail smelter, where work was stopped for several months in an effort by the men to obtain an eight-hour day. These are illustrations of how industry may be interfered with and production diminished through a spirit of discontent and dissatisfaction among workers. The mineral output of British Columbia in 1916 was \$42,290,462; in 1917 it dropped to \$37,182,570, the difference being attributed to these disturbances. It is Mr. Sloan's hope that with the grievances settled, the present year will be free of such trouble, and mineral production of the Province will rise to the 1916 mark and, possibly, to the \$50,000,000 mark.

Coal-mine operators of British Columbia are not in favor of the contemplated legislation. They have lodged their protest with the Minister of Mines. They argue that shorter hours will mean less production at a time when, because of the demands of the War, greater output is essential. They say in effect: "We do not object to the principle of this legislation, but we think it is inopportune." In discussing the matter with Mr. Sloan, they suggested that the proposed law might be deferred to six months or a year after the end of the War. In this connection reference was made to the large exports of coal from the United States to Canada.

last year to meet a shortage in the Dominion, which threatened a serious industrial and domestic situation when coal was much needed in the United States. It was stated that, while this had been done once because of an unexpected emergency, it scarcely could be expected to be repeated. The Dominion Government, consequently, was expecting an output from western Canada of 2,500,000 tons more coal this year than in 1917, in order that the contemplated demand might be met without extraordinary calls being made on the United States. This was cited as proving the imperative necessity not only of maintaining, but of speeding-up production in British Columbia.

No soldier, or sailor, or member of any of the Allied forces engaged on active service in connection with the War, who holds mineral interests in British Columbia is permitted to suffer material loss because of his or her enforced absence from the country. The personal pronoun 'her' is used advisedly, as the law applies to nurses engaged with the military or naval forces. The free miner's certificate, which is the basis of the mining laws of the Province—it being necessary that it shall be renewed every year and without which no mineral right can be held, apart from a Crown Granted mineral claim—is maintained in good standing for those so occupied. They are not required to do the usual assessment work required on claims and, in the event of their death, the rights of their heirs are fully conserved. The legislation, of which this is a brief and general outline, has been re-enacted by British Columbia from year to year since 1914. At the present session of the Legislative Assembly, however, the Act was made operative for the continuance of the War and for a period of six months thereafter.

LEAD, SOUTH DAKOTA

Manganese, Molybdenite, Oil, and Spodumene Mining; Recent Developments.

Roubaux.—The Custer Peak Copper Co. has started enlargement of its main shaft to one of three compartments. The mine has been opened to a depth of 300 ft., while considerable lateral work is completed on two levels. Some new mine equipment will be added, and some changes will be made to the plant before concentration is resumed.

Custer.—Machinery for the 100-ton concentrating plant under construction by the Spokane Lead & Silver Co. has all arrived, and is being erected. It is expected to place the new plant in commission early this summer. Development of the mine continues favorable.

Hill City.—The Blue Lead company has started work at its copper mine. Old workings are being re-timbered and placed in shape for continuous operation. One car of dump ore shipped during the past year returned over 6% copper. Regular shipments of this material will be made.

The Dakota Continental Copper Co. is making arrangements to resume diamond-drilling. This work will be done from the lowest workings, and will be continued for several months. The Summit mine has been undergoing development by this company for the past 16 months.

Keystone.—The Rheinbold Company and the Standard Essence Co. have again commenced the shipment of lithia ores to New Jersey. Since late last fall none was sent for the reason that carload lots would not be accepted for points east of Chicago. This difficulty has been adjusted, and regular shipments will be made. Five cars are being loaded with spodumene and amblygonite.

Ardmore.—With the return of moderate weather, development of the field north of here has again commenced in earnest. The Shiloh Oil & Refining Co. continued drilling throughout the winter, and its well is nearly 2000 ft. deep. —The Hat Creek Co. has a well down over 650 ft. and

has resumed drilling after a suspension for winter.—The Wykota Oil Refining Co. has started a well and is making good progress. The bringing-in of any one of the above wells will prove the field, and indications point to the presence of oil at a depth of about 2000 feet.

Central City.—Al Fish and associates have discovered a deposit of molybdenite on their property on False Bottom

PRINCIPAL CENTRES IN THE BLACK HILLS OF SOUTH DAKOTA.

creek. Only a small amount of work has been done, but this will be continued during favorable weather. The material is found in a 'vertical', and is of a good grade.

Lead.—Since the shipment of one car of manganese from the Fremont property, development of this mineral has been started on other claims. In Strawberry gulch, James Brown has opened ore, while deposits in the vicinity are being developed. At the Kilorne property, near Rochford, manganese is being developed, and it is anticipated that several mines will be producers. At some of the properties there seems to be an excess of silica, so it is probable that a concentrating plant will be erected to dress this ore.

TONOPAH, NEVADA

Extension and West End Developments.—Divide District Railway.

The Tonopah Extension company reports that connection has been made from the 1680-ft. level of the Victor with the intermediate drift from winze No. 1501 on the Murray vein. The raise proves the persistence of the Murray vein a vertical distance of 200 feet.

A compressor has been erected at the Ohio shaft of the West End mine. This machine, with that at the West End shaft, permits of more development at the Ohio. The 800-ft. level of the West End is being driven to connect with the Ohio. An electric haulage system will be put in.

Surveyors of the Tonopah & Goldfield railroad have been making a preliminary survey from Tonopah to Gold Mountain. Another survey will be started from some point between Tonopah and Goldfield. In all probability the new district will have a spur connection with the main line in the near future.

The Silvermines Corporation at Hornsilver has experienced financial difficulties, and is in the hands of a receiver. The mill is being operated as usual.

THE MINING SUMMARY

ALASKA

Deposits of chromite have been known in Alaska for a number of years, but they became of economical interest only in 1917. The deposits of present interest, according to the U. S. Geological Survey, are at the south-west end of Kenai peninsula, in two areas, one along the north shore of Port Chatham and the other at Red Mountain, about 16 miles to the north-east. Both deposits occur in bodies of altered peridotite, and, so far as known, these are the only bodies of peridotite in this vicinity, but exploration farther

MAP SHOWING SITUATION OF CHROME DEPOSITS ON KENAI PENINSULA, ALASKA.

from the coast, in the mountains, may reveal others. Peridotite of the same kind also occurs in large and small masses at several other places in the area between Yukon and Tanana rivers, and at Livengood, in that area, there is a deposit of chromite, but the ore in the interior of Alaska could not be mined profitably except when prices are high. The deposit now being mined is on a spit at the south-east end of a peninsula known as Claim point, which projects south-eastward into Port Chatham. This peninsula measures about 4000 ft. from east to west and about 2200 ft. from north to south, and is joined to the mainland by a neck of land about 200 ft. wide. About 800 tons of ore containing from 46 to 49% of chromic oxide was mined in 1917, and about as much more remains available above half tide. Ultimately it will be necessary to work from a shaft or cofferdam and hoist ore to the surface, a method that will increase materially the cost of mining.

Juneau.—Alaska Gastineau in March treated 150,093 tons of ore assaying \$1.114 per ton. Loss in residue was 20.5c. per ton. For first quarter of 1918 the following figures are available.

Month	Tons	Gross value	Tailing value	Extraction %
January ...	197,300	\$0.903	\$0.200	77.85
February .	140,305	0.934	0.189	79.76
March ...	150,093	1.114	0.205	81.60

Kennecott.—A threatened strike on the Copper River railroad was averted by an adjustment of wages. In March the Kennecott company produced 5,772,000 lb. of copper,

compared with 5,888,000 lb. in February and 5,970,000 lb. in January.

ARIZONA

Ajo.—The New Cornelia ore has improved in grade from 1.54 to 1.65% copper. An experimental flotation plant is to be erected. The company produced 3,218,000 lb. of copper in March, compared with 3,606,000 lb. in February, and 4,136,000 lb. in January.

Bisbee.—Calumet & Arizona produced 4,386,000 lb. of copper in February, against 2,900,000 and 4,748,000 lb. in the preceding two months.

Shattuck-Arizona company produced as follows in March, and for first quarter:

Month	Copper, lb.	Lead, lb.	Silver, oz.	Gold, oz.
January ...	849,440	84,000	9,599	106
February ...	854,042	66,765	6,590	73
March	1,013,593	66,878	11,429	89

The mill building is complete, awaiting machinery.

Clifton.—The Arizona Copper Co. produced 4,000,000 lb. of copper in March, against 3,600,000 lb. in February, and 2,500,000 lb. in January.

Globe.—Old Dominion produced 2,872,000 lb. of copper in March, against 2,841,000 lb. in February, and 3,400,000 lb. in January.

Metcalf.—Shannon Copper Co. produced 962,000 lb. in March, against 788,000 lb. in February and 972,000 lb. in January.

Miami.—Production of Miami Copper Co. in March was 5,174,365 lb., against 4,709,484 lb. in January. This is the highest yield since work was resumed last August.

Inspiration Consolidated produced 8,750,000 lb. of copper in March, compared with 6,200,000 lb. in February, 5,000,000 lb. in January, 5,600,000 lb. in December, and 2,500,000 lb. in November. The mill is now at full capacity.

Prescott.—The old Peck silver mines in the Bradshaw mountains are to be re-opened by C. E. Battan and others of El Paso.

ARKANSAS

Yellville.—Three important deposits of zinc ore have been found by drilling on Cowans Barrens plateau, south-east of this place. One hole cut ore from 64 to 80 ft. depth, assaying 9% blende. At 160 ft. the ore carried 12.5%, and at 260 ft., 16%. Another hole is to be drilled.

CALIFORNIA

Colfax.—A half interest in the Black Oak gold mine has been acquired by D. A. Russell and Lee Gray, and work will be resumed soon. The property, which formerly yielded rich ore, has been idle several years.

Rising Sun is said to be developing well. Deeper work is to be done. A cyanide plant is in operation. Hathaway & Martin of Nevada City are in control.

Engelmine.—The Mason Valley Mines Co. of Nevada has taken over the M. B. H. copper mine near here. Prospect are said to be good.

The Engels Copper Co. has appointed Duane Rebstock of Arizona to take charge of the safety-first department.

Kennett.—Wage differences between Mammoth Copper Co. and its mechanics have been settled by arbitration of the Federal Wage Commission. The men were allowed advances varying from 5 to 10%. While they are not all satisfied, they will abide by the ruling.

Redding.—The American Gold Dredging Co. is to increase its capital from \$15,000 to \$60,000. The company is assembling material to build a dredge on the Menzel ranch, recently purchased, across the river from Redding.

Winthrop.—Bully Hill mines and 15-mile railroad, owned by the General Electric Co., has been taken under option by the A. S. & R. Co., the first payment being made recently.

Yreka.—Irwin brothers, F. W. Williamson, and Roy Howell are developing a promising group of copper mines adjoining the Evergreen cemetery near Yreka. The first-named have made an initial shipment of chrome from their Greenhorn district property.—Papas and Bellnap have taken a lease on Morgan brothers and Herzhog mercury mine, on Empire creek.—The Mercury company of Yreka has acquired the quicksilver mines at Cinnabar spring, 30 miles west of Hilt, and will equip with modern machinery.

COLORADO

Boulder.—The Slide Gold Mining Co. at Gold Hill is successfully treating low-grade ore from the dump. Flotation is employed in the plant. The old mine is to be re-opened, the 1000-ft. shaft being unwatered at present. G. W. Teal is manager and Charles Gustafson is superintendent.

The Horsfal gold mine, recently re-opened after being shut for 30 years, is showing good ore at 400 ft. Shipments will be started soon. C. O. Oliver is in charge.

Creede.—The Collins and Wheeler lease on the Quintette property is shipping 30 tons of ore per day averaging over 100 oz. silver. The orebody, as far as developed to a depth of 100 ft., is 20 ft. wide and 80 ft. long.

Creede Exploration Co. is prospecting below the level of the Nelson adit. Drifts are being driven both ways from the Berkshire shaft on the 100-ft. level. The Commodore shaft has been unwatered to the bottom, 450 ft. below the adit-level, where a station is being cut. This company's prospecting operations at the King Solomon mine did not result satisfactorily, and work there was stopped.

Lessees are shipping from the Bachelor, Commodore, and Last Chance-Del Monte mines.

Creede United Co. is getting a little ore from the Happy Thought mine and concentrating it by occasional operation of the Humphreys mill.

The Equity mine is shipping regularly.

Cripple Creek.—Hayes and Carter, lessees on 1200-ft. level of Vindicator, have opened a new shoot 30 ft. wide, all of shipping grade. Coarse ore assays 1 oz. and screenings 4 oz. per ton.

Red Mountain.—Crawford Mining Co. has been operating in this district during the winter, and will be among the large producers this year. Shipments will probably start with opening of the railroad. The road from the Eastow mill to the Genessee mill is reported to be open. Warren Prosser, superintendent of the properties, reports conditions good and expects the tonnage to exceed greatly that of 1917. These properties were formerly under lease to J. M. Hyde, and were known as the Genessee.

Telluride.—The Lewis mine is opening new ground, while its mill has been closed down temporarily.

Molybdenite ore has been mined near Norwood and the operators are trying to get a mill to treat it.

The Tomboy has been making large shipments of iron concentrate.

The Smuggler Union has been steadily increasing its shipments.

Wagon Wheel Gap.—The fluorspar mine is shipping 2000 tons per month. Most of the product is shipped to steel mills in different parts of the country for flux, but some shipments of 98% pure fluorspar are shipped to Eastern chemical works.

IDAHIO

Hailey.—The Mascot M. & M. Co., in charge of H. E. Johnson, is to drive a 3000-ft. adit to prospect its P. K. claims. Drills will be used.

Kellogg.—Nabob Consolidated has cut its Denver vein at 900 ft. depth. It is over 8 ft. wide, two feet carrying lead-zinc ore. W. A. Beaudry is manager.

Wallace.—Dividends paid by companies in the Coeur d'Alene region for first quarter of 1918 were as under:

Company	Amount
Bunker Hill & Sullivan	\$490,500
Hercules	750,000
Hecla	50,000
Interstate-Callahan	232,490
Federal	209,757
Tamarack	53,287
Caledonia	234,450
Big Creek	5,000

Total\$2,025,484

A year ago the total was \$2,599,940, and in last quarter of 1917, \$2,018,940.

Success Mining Co. is doing much better under new management. Ore production in January and February was valued at \$68,962, of which \$23,915 was profit. Losses were previously made. On 1500-ft. level is a new shoot 80 ft. long so far as opened. Mill is dressing 97 tons daily, averaging 14% zinc, 4% lead, and 10 oz. silver per ton. Tailing contains 1.6% zinc and 0.14% lead. There are 80 men employed.

Rex Consolidated Mining Company has been re-organized, and is clear of debt. New capital is 5,000,000 shares of 25c. par value. Mining will be resumed at once. Main shaft is to be sunk 500 ft. below present lowest level. Upper levels and mill are to be leased.

Wardner.—Bunker Hill & Sullivan old ground above this place is being worked by about a dozen different lessees. All are reported to be mining good lead-silver ore and making profits.

KANSAS

Baxter Springs.—Royalties paid to Kansas farmers and Oklahoma Indians by lessees of zinc-lead lands during 1917 amounted to \$1,257,000. Value of ore mined was \$16,769,900, on which 7½% royalty was paid. Indians received \$755,000 of the total. Proved mineral area is 44,000 acres, which is being extended rapidly.

Chanute Spelter Co. has 37 drills at work, and expects to add 15 more. New mills under construction will soon be finished.

Big Elk Mining Co. is to erect a 600-ton mill on its lease 4 miles south-west of this place. J. H. Mathews is president.

MICHIGAN

Houghton.—Calumet & Hecla has arranged with Minerals Separation to become a licensee under its flotation patents. The White Pine flotation plant will be ready by May 1. It is to have a daily capacity of 1000 tons, receiving material following Gates crushers, Hardinge mills, and Wilfley tables. During March there was 18,000 tons of ore concentrated at the mill. In 1917 the White Pine crushed 212,889 tons of ore, carrying 19.11 lb. per ton. Output was 4,067,529 lb. copper, at cost of 14.99c. per lb., and \$2.365 per ton of ore. Profit was \$397,223, after paying all charges, including

taxes. In 1916, 188,890 tons of 22.27 lb. ore yielded 4,207,449 lb. copper, at a cost of \$2.082 per ton.

MISSOURI

Joplin.—Production of the Missouri-Kansas-Oklahoma region last week was 9165 tons blende and 1458 tons lead, averaging \$43 and \$84 per ton, respectively. Total value was \$515,285, making \$6,833,902 for 14 weeks. Oklahoma contributed \$377,582.

The April 7 issue of 'Joplin News Herald' was a mining and industrial edition of 80 pages, covering every phase of the zinc-lead region's activities. We are abstracting freely from this issue.

Southwest Missouri Mine Safety and Sanitation Association and a local committee of 15 is to proceed to Washington to ask for a stabilizing of the zinc market. Present prices for ore are considered far too low.

MONTANA

Butte.—Anaconda produced 28,000,000 lb. of copper in March, also 5,000,000 lb. of zinc.

Butte & Superior reports as follows for first three months of 1918:

Month	Zinc in concentrate, lb.	Silver, oz.	Recovery %
January	14,300,000	265,000	94
February	12,500,000	250,000	95
March	15,000,000	285,000	94

Troy.—Snowstorm Mines Consolidated No. 1, 4, and 7 adits are being driven. No. 1 has been driven 300 ft., of which 200 ft. is in ore. No. 4 has been advanced 1300 ft. in ore. Work on No. 7 was started with two shifts on April 1. This is the lowest opening in the property. It is on the same level as the railroad, and will become the outlet for everything. Ore being delivered to the mill is the best yet. Zinc concentrates are to be sent to the Anaconda company's works.

NEVADA

Austin.—Cinnabar has been found by C. B. Smith 30 miles from rail. Several samples assay 1.7% mercury.

Copperfield.—Washoe Copper Co. is establishing a new camp 1½ miles south-east of the Nixon-Nevada main shaft, where it will start an adit to develop the southern portion of its 720-acre property. An engine and compressor-house, blacksmith-shop, cook and bunk-houses, and a number of cottages will be built. A 10 by 10-in. Ingersoll-Rand Rogler type compressor, to drive five jack-hammers, is at Copperfield station, and a 50-hp. Western gasoline engine, as well as other machinery and tools necessary, have been ordered. R. J. Jefferson, of Reno, is managing director.

Jungo.—Oklahoma Gold Mining Co. has arranged for resumption of work early in April. A mill was erected last summer and a large quantity of gold ore blocked out. The mine is in Pine Forest range, near Quinn River crossing. Thomas Ewing is general manager.

Mill City.—A small concentrator for local antimony ore is nearing completion. There is said to be sufficient ore assured to keep the plant running for a long period. The Bloody Canyon and other mines are producing high-grade antimony ore. John Ross is manager of the plant.

National.—National Treasure Mines Co.'s property here has been examined by J. H. Weber of Salt Lake City. Adits show two zones of andesite, also belts of basalt and rhyolitic tuffs. These are intrusive and not much ore will be found in them. Most of exploration has been done at wrong points. It is suggested that a vein at mouth of long adit be prospected.

Tonopah.—The Divide (Gold Mountain) district continues to boom. By the coming fall the Tonopah & Goldfield

Railroad Co. will have a line in operation.—The Gold Wedge Mining Co. was incorporated on March 30, with capital of 1,500,000 shares, 10c. par. William Forman of Tonopah is president.—The East Divide Mining Co. has been formed with a capital of \$150,000 by W. E. Jenkinson, A. Dumond, and Ben Gill of Goldfield.—The Ben Hur Mining Co. was organized with capital of \$100,000 by H. P. Campbell and R. J. Kelly of Tonopah.

NEW MEXICO

Kingston.—The South Percha silver mine, about 4 miles south, is yielding ore after a shut-down of 25 years. C. P. Brown, of the Empire Zinc Co., is general manager for the company which has acquired these mines.

Mogollon.—Mill building of Socorro company is making good progress. Ball-mills will be used in place of stamps. Power arrangements are to be better than in the former mill.

Oaks Co. has completed timbering its Pacific shaft. Work is under way on No. 5 level.

Tailing flume on Silver Creek is being extended to dam constructed by local companies.

OKLAHOMA

Commerce.—An oil-flotation plant is to be erected at the tailing mill of Mark Pierce and Lloyd Judd.

Picher.—Production of the region last week was 5669 tons blende and 927 tons lead, worth, including 1500 tons of blende previously unreported from St. Louis-Quapaw, a total of \$377,582.

Texas Mining Co., two miles east, has nearly completed a 300-ton mill and other plant. Rich ore—20 to 30% blende—was opened at 176 ft. depth. Water is troublesome. H. H. Holeman is manager.

Keltner Mining Co. is developing rich ore and erecting a 500-ton mill. Ore is 17 ft. thick and drilling continues to prove rich zinc-lead ore.

Quapaw.—Bethlehem Zinc Co. is to erect a 300-ton mill on its lease here. H. H. Hughes is superintendent.

OREGON

Baker.—Ben Harrison gold mine, under option to E. H. Dewey of Nampa and others, has been returned to the company. About \$50,000 was spent during the option.

Gold Hill.—Rainier Mercury Co. of Seattle has been organized in Jackson county, with T. H. Ellis, president and general manager, and headquarters at Beagle, Oregon. This new corporation takes over the Utah Quicksilver Co.'s 35 claims in the Meadows district, 12 miles north of Gold Hill, also the Samuel Bertleson group adjoining. These properties are contiguous to the Chisholm group, which have been producers since 1878, and are now operated with a 12-pipe furnace to reduce the ore mined during development, and pending the arrival of a 200-ton plant to be selected.

TEXAS

Austin.—Nitrate deposits are said to have been discovered in Presidio county, near the Rio Grande, and up to April 1 there had been granted claims covering 3840 acres.

El Paso.—The new No. 4 reverberatory furnace at the El Paso furnace was blown-in on April 6. This furnace is designed for fettle-feeding, using mostly Chino concentrate, with admixture of silicious ores. It is 130 ft. long and 30 ft. wide, with the usual up-cast flue to Stirling boilers for recovery of waste heat. The blowing-in of the furnace gave promise of most favorable conditions for rapid smelting, the first skimming taking place 30 hours after dropping the first charge, which is quick work for a large furnace. The copper-smelting department of the El Paso smelter is in charge of Alan F. McCormick.

Grand Saline.—The Grand Saline Salt Co. is erecting

three large brick buildings here, in which will be installed vacuum-pans, pumps, etc., for refining salt by the vacuum-tank method.

UTAH

Alta.—New railroad into this district is expected to be ready for carrying ore by May 1. It will have a daily capacity of 200 to 300 tons. Little Cottonwood Transportation Co. controls the line, in charge of H. A. Dunn.

Michigan-Utah Consolidated Mines Co. reports as follows for 1917, compared with previous years:

	1917	1916	1915
Ore, tons	12,014	6,991	3,319
Gold, ounces	227	154	67
Silver, ounces	148,318	90,812	43,136
Copper, pounds	384,906	364,685	99,066
Lead, pounds	1,865,379	716,851	515,296
Net receipts	\$244,125	\$130,342	\$29,901

Property consists of 66 claims, two being acquired in 1917. Considerable work was done from the Copper Prince adit, now in 2097 ft. A large body of ore assaying 0.025 oz. gold, 1.84% copper, 7.8% sulphur, and 52.2% iron has been developed.

Dugway.—A 100-ton smelter is to be erected in this district by the Dugway Smelting Co., work to be started in 60

MAP SHOWING SITUATION OF DUGWAY, UTAH.

days. The plant will be 47 miles from Faust, the nearest rail point. Copper ore will be supplied by a number of properties. Company has a capital of \$20,000, shares 1 cent par. A. L. Thomas Jr. is president and manager and Otto Stallman, consulting engineer. Company's prospectus says that oreserves in the Dugway Bertha mine are 90,000 tons, in addition to which the Lucky Star, Dugway Copper, Dugway Lining, Copper Bell, Continental Mining, Lundine Bros., and other properties in the district are developing a large tonnage for the smelter. While the first unit will be of 100 tons daily capacity, power will be installed sufficient to operate a 250-ton stack. The Dugway Smelting Co. is contracting with the mines to smelt the ore on a basis of \$12 per ton, with the usual bonuses and penalties, and the tests made by Messrs. Stallman and Peugeot show that the total cost of smelting this ore in a 100-ton stack cannot exceed 5.25 per ton, and this will be reduced as the capacity is increased. The Dugway ores are ideal for smelting, practically carrying their own flux. This will give the Dugway melting Co. a profit in excess of \$1000 per day, and with increased capacity the profits will be more than proportionately larger. As a rule, the public is not cognizant of the large profits in smelting, as the returns are so large and are that the public has never been given a chance to invest,

all the capital being furnished by close corporations. A general metallurgical analysis of the copper ore of the Dugway district proportioned to the tonnage, is as follows: moisture, 5.2%; silica, 24.1%; iron oxide, 29.9%; copper, 4.9%; sulphur, 18.7%; alumina, 9.2%; lime, 7%; magnesia, 2%; silver, 6 oz.; and gold, 0.7 oz. per ton.

Green River.—Nickel is said to have been identified in pyrrhotite in the Henry mountains by H. A. Hatch. Samples analyzed at Denver showed 6% nickel.

Milford.—In the Yellow Pine mine, 10 miles south of here, a winze below the 100-ft. level shows good ore, and a carload averaging 12 to 17% copper and 10 oz. silver has been shipped to smelters. William Eyre is part owner.

Development by Leonora M. & M. Co. in 1917 amounted to 805 ft., according to manager, John Matson. East drift is in 1900 ft. from shaft. High-grade gold-silver-lead-copper ore has been opened.

Tintic.—Grand Central Mining Co. paid 5c. per share, equal to \$25,000, on April 12. This makes \$1,759,750 to date.

On April 8 the Tintic district Miners Union took a strike vote on the following grounds: "It is to the interest of all members to attend this meeting and vote for or against a strike, as all loyal Americans realize that conditions imposed by the companies of this district will not permit us to support our Government as we desire. Up to this time we have received but one communication recognizing us as citizens, organized in a bona fide labor organization, recognized by our Government." The men also demand an increase in wages of 50c., recognition of the union, abolition of the rustling card, and no more assignments of wages. Present minimum wage for skilled men is \$4.25 to \$4.50.

On April 6 the Chief Consolidated, Eagle & Blue Bell, Centennial Eureka, Gemini, and Ridge & Valley mines announced a 25c. raise in wages, to take effect May 1. Semi-monthly pay-days are also to be started.

Whiterocks.—Cedar Butte Oil Co., in the Uintah basin, is to build a 300-ton plant to treat saturated oil-sand. Oil is to be extracted by a hot solvent. P. S. Coke is managing director.

WASHINGTON

Boundary.—Maple Leaf mine in Stevens county, 2 miles from the international border, is being developed by Melrose Mining Co.—Spokane and Boundary people. F. M. Ludell, of the latter place, is vice-president. F. A. Heinze is said to have spent \$50,000 in exploration, and cut the vein in a 2000-ft. adit. After he retired, others found ore by driving 10 ft. farther. Some rich copper-silver ore has been exposed. Machinery is to be ordered when roads permit hauling.

Northport.—The Electric Point Co. in 1917 received \$553,522 from ore sales. Expenses totaled \$219,120. Net profit was \$80,129, all being paid in dividends. Difference is accounted for in \$243,019 written off for depletion of ore and \$7282 for depreciation. Ore blocked out is estimated at 15,000 tons. At the mine the shaft is down over 700 ft. on its way to 1000 ft. depth. On the 200-ft. level there were five 'chimneys' of ore, but on No. 6 only one has been opened so far, although equal to the upper levels. Carbonates predominate, but sulphides are expected at water-level, probably above 1000 ft. Ninety men are employed. Shipments continue to the Northport smelter. R. A. Young is manager.

CANADA Ontario

The third year's operation of the Ontario Workmen's Compensation Act shows for 1917 that compensation totaled \$2,913,086, against \$2,011,469 in 1916. Accidents of all

kinds amounted to 36,514, an increase of 10,422. There were 454 fatalities. These figures relate to all industries. Expenditure by the administration was \$133,630.

Cobalt.—Work in the Lightning River district has been suspended, except where special permit is granted by officials of the Mines Department. The gold discovery is situated within the timber limits of the Abitibi Power & Paper Co. At the present time an inspector is on his way to the area to study the situation.

Porcupine.—The West Shining Tree gold district, 20 miles south-west of Kirkland Lake, is reported to be very active. At Cashbow station on the Canadian Northern there is 100 tons of supplies awaiting transport to the field, a distance of 30 miles. The Wasapika, Churchill, and Kingsley properties show good ore. These, with the Burke-Bullock, Caswell, Holbrook-Tour, Holden, Atlas, and Longtype, are being developed.

A feature in the goldfields of this Province is the large number of changes in the management of the various mines. Notable among these is the Hollinger, Tough-Oakes, Schumacher, Teck-Hughes, Dome Lake, West Dome, and Kirkland-Porphry. At each of these, since the beginning of the year, changes have been made.

CHILE

The law covering taxation on exportation of copper and iron states that for ten years after the date on which the law goes into effect mine-owners must pay the Government 5% of annual profits, 36c. (U. S.) per ton on iron ore (with certain return privileges), 5% when blister copper is worth \$291 to \$388 per ton, 5% plus 6% between \$388 and \$485 and over, 11% for over \$485 plus 7% of the excess in price over \$485 per ton, same taxes for electrolytic, save that the low limit is \$267 per ton, and ore and matte pays half the corresponding taxes for bar copper. Taxes collected are to be spent in aiding the mining industry. During period of present War, copper in form of metal, matte, and ore will pay as above, based on \$388 per ton, plus 8% on excess over that price. Electrolytic will pay same rate of 8% based on minimum of \$340 per ton.

Sewell.—The Braden Copper Co. produced 5,248,000 lb. in March, compared with 4,754,000 and 6,200,000 lb. in February and January.

MEXICO

Agascalientes

Agascalientes.—The American Smelting & Refining Co. has decided to make a voluntary contribution of \$1600 gold monthly over a period of one year to the State of Aguascalientes, to expedite restoration of stable government. In return the State authorities have annulled a law by which attempt was made to levy a production tax of \$9000 on the output of the smelter. Rather than submit to this impost the company had suspended operations at this plant and brought suit against constitutionality of the law in the Mexican Supreme Court. The suit will now be dropped and smelting activities resumed.

Chihuahua

Chihuahua.—The Chihuahua smelter of A. S. & R. Co. has been blown-in after a long suspension due to operation of bandits in its territory. The company has in progress reconstruction work that will greatly expand its capacity at Chihuahua, including erection of new copper smelter and lead plant.

Sonora

Cananea.—Greene Cananea produced 4,480,000 lb. of copper in March, against 3,960,000 lb. in February, 3,130,000 lb. in January, and 1,650,000 in December. Silver output in March was 130,400 oz., and 1225 oz. gold.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Samuel H. Dolbear is in Oregon.

B. B. Gottsberger has returned to Miami from New York. **D'Arcy Weatherbe** is at Toronto, on his return from London.

James P. Gaskill has an office in the Security Bdg., in Los Angeles.

R. B. McGinnis is at Alice Arm, British Columbia, for the summer.

A. P. Root, of Silverton, passed through San Francisco on his return from San Diego.

J. L. Bruce has returned to Butte after a visit to Ray, Hayden, and Globe, in Arizona.

F. A. Fahrrewald, of Cleveland, is inspecting deposits of secondary minerals in California.

Clarke Sullivan is Captain in the Engineer Officers Reserve Corps, and is now at Metcalf, Arizona.

D. M. Kerr has accepted an appointment with the Broken Hill South company at Broken Hill, N. S. W.

Charles H. White is now Captain in the Officers Reserve and is stationed at Watertown, Massachusetts.

R. G. Hall, general manager to the River Smelting & Refining Co., St. Louis, was here during the week.

John Tait Milligan has been made general manager for the Afterthought Copper Co., relieving J. T. Robertson.

John E. Hardman and **J. Stevenson Brown** have been elected honorary life-members of the Canadian Mining Institute.

L. W. Ledyard, formerly manager of the Teck Hughes at Kirkland Lake, Ontario, has been appointed general manager of the Kirkland-Porphry mine.

W. J. Sharwood is chemist, and **Allan J. Clark** is metallurgist, to the Homestake Mining Co. This is to correct an error made in a recent issue of this paper.

George Baer, for a number of years mine superintendent for the Socorro Mines Co., Mogollon, New Mexico, is leaving to take a position with a large copper company in Cuba.

Frank H. Sistersmans will shortly return from Cuba, where he has been managing manganese mines for Eastern people, and will make his headquarters at El Paso, Texas.

Robert M. Keeney, manager for the Ferro Alloy Co., at Denver, Colorado, is acting as consulting engineer for the Anaconda Copper Mining Co. at its new plant for making ferro-manganese.

A. G. McGregor, smelter construction engineer, has been at La Fundición, Peru, investigating the proposed alterations to the Cerro de Pasco works. He is also to visit Chuquicamata and Sewell in Chile.

Kuno B. Heberlein has resigned as president of the Compañía de Minerales y Metales, Compañía Minera de Penoles, and Compañía Minera de Paloma y Cabrillas, Mexican subsidiaries of the American Metal Company.

Thomas Treloar, well known at Butte, Montana, died on April 2. He was born in Cornwall in 1842, coming to the United States in 1886. He had been connected with Butte mines since 1888. He leaves three sons, a daughter, and a wife.

E. E. Barker, who has been mining superintendent for the Chile Exploration Co. at Chuquicamata, Chile, since the beginning of work at that property, has resigned his position to become superintendent of mines for the Cerro de Pasco Copper Corporation at Cerro de Pasco, Peru. After spending a few months in New York, Mr. Barker has again returned to South America.

THE METAL MARKET

METAL PRICES

San Francisco, April 16

Aluminum-dust (100-lb. lots), cents per pound.....	70
Aluminum-dust (ton lots), cents per pound.....	65
Antimony, cents per pound.....	15 1/2
Antimony (wholesale) cents per pound.....	13 1/4
Copper, electrolytic, cents per pound, in carload lots.....	23 1/4
Copper, electrolytic, cents per pound, in small quantities.....	24 1/2
Lead, pig, cents per pound.....	7 1/4
Nickel, cents per pound.....	53
Platinum, pure and with 10% Iridium, per ounce.....	\$108-\$116
Quicksilver, per flask of 75 lb.....	\$115
Spelter, cents per pound.....	10
Zinc-dust, cents per pound.....	17 1/2

The platinum situation at San Francisco was discussed here last week by the Manufacturing Jewelers' Association. It was found that there is only 100 oz. of the metal here, and the jewelers voted to give the Government first call on 50 oz. at \$108 per ounce.

ORE PRICES

San Francisco, April 16

Antimony, 45% metal, per unit.....	\$1.10
Chrome, 38% and over, f.o.b. Cal., per unit.....	\$1.25
Magnetite, crude, per ton.....	\$8.00-10.00
Manganese, 40 to 50%, cents per unit.....	92-110
Manganese, chemical, per ton.....	\$80-100
Tungsten, 60% WO ₃ , per unit.....	\$20-24
Molybdenite, per lb., 85% MoS ₂ (nominal).....	\$1.80
Pyrites, domestic, per unit of sulphur, cents.....	28

Magnetite deposits in Venezuela are to be developed on a large scale by the Magnetite Products Corporation, of which Chas. E. Doddridge of New York is president. Estimated quantity is 300,000 tons, averaging 48.31% FeO, 0.43% Fe, 0.44% CaO and 50.03% CO₂. The ore is on the coast, and will be mined by open-cut. Shipments of 1000 tons monthly to America are contemplated.

EASTERN METAL MARKET

(By wire from New York)

April 16.—Copper is unchanged. Lead is dull, though steady. Spelter is inactive and lower.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.67c. for small lots, effective until June 1, 1918. Quotations in cents per pound are as under:

SILVER

Below are given official or "ticker" quotations, in cents per ounce of silver 999 fine. The actual figure at which the metal is bought and sold is a matter of negotiation, and is not available, but the prices given include such approximately. Premiums are paid up to 3c. per oz. See "M. and S. P." of March 23, 1918, for full details.

The silver bill before Congress is, briefly, to retire silver certificates, to borrow from the Treasury the silver for use for war purposes, and then, borrowed by purchase in the market at the fixed price of \$1 per fine ounce, and to replace the borrowed silver by coining the new silver acquired for that purpose into standard silver dollars. There is no limit in which this

must be done. Commenting on this proposal, the four principal bullion brokers in London—Samuel Montagu & Co., Mocatta & Goldsmid, Pixley & Abell, and Sharps & Wilkins—as stated in the "Financial Times," is briefly as follows: (1) "The most important event that has occurred in the silver market for some time past"; (2) "That the release of so much silver should be treated as a 'bull' point strikes one as an anomaly, and it would be so were it not for the fact that the bill is to provide for the gradual re-purchase by the American government of this silver at about \$1 per oz., which, of course, is considerably higher than any price ruling for some time, and the anticipation of this naturally stiffens the backs of sellers and encourages them to hold off"; (3) "The addition of silver made available should be sufficient to meet all requirements for some time"; (4) "More buying in London has been induced."

LEAD

Lead is quoted in cents per pound, New York delivery. Government metal receives 7c. per lb. until August 6.

100% basis the range was from \$40 to \$55, most ore selling at \$15 per ton.

Commenting on metal markets in 1917, the A. S. & R. Co. states that the peak of high prices, save that of zinc, was reached during the first half of the year. Since then there have been serious declines, as follows: copper from 33 to 23 3/4c., lead from 11 to 5 1/2c.; silver from \$100 to 78c., and spelter from 13 to 7 1/4c. These results, it said, have been partly

Zinc-ore prices at Joplin, Missouri, dropped \$5 per ton last week. On 60% basis the range was from \$40 to \$55, most ore selling at \$45 per ton.

Commenting on metal markets in 1917, the A. S. & R. Co. states that the peak of high prices, save that of zinc, was reached during the first half of the year. Since then there have been serious declines, as follows: copper from \$3 to 23½c., lead from 11 to 5½c.; silver from \$1.00 to 78c., and spelter from 13 to 7½c. These results, it said, have been partly brought about by Government actions.

Eastern Metal Market

New York, April 10.

Two of the metals have developed further weakness; inactivity is pronounced in all of them.

The copper market is devoid of interesting features and is unchanged.

It is still difficult to do any business in tin for future delivery, and spot metal is practically unobtainable.

Lead has declined sharply and demand is very light.

Zinc continues to weaken and is lower than a week ago.

Antimony has softened and is in poor demand.

The most significant development of the week in iron and steel is the definite shaping of Government plans for the immediate building of larger gun-works than now exist, also for a corresponding increase in the manufacture of the largest shells in these new plants. This will include many 16-in. howitzer mounted trucks, to be made by a great concern not now engaged on guns, and for delivery late in 1919 or early in 1920. This vast enlargement in our offensive preparations, revealed in the last two weeks, has stirred the machine-tool trade also. The first week in our second year of war clearly indicates that the American steel output will finally be almost entirely absorbed, to the exclusion of so-called ordinary uses at home or abroad. The steel-ingot output in March is estimated at 3,525,000 tons, based on returns from 29 companies, making 85 to 90% of the entire output. This parallels the remarkable recovery in pig-iron output made in March.

COPPER

General conditions remain unchanged from last week or some weeks previous, and the market is featureless. On what appears to be good authority we learn that one of the biggest men in the copper industry has recently returned from conferences at Washington more convinced, or more confident, that the price of copper will be 25c. per lb. after June 1. The country's production is increasing each week, and will probably equal 200,000,000 lb. in April. This is based on the reports of several large companies for March, showing a decided increase. Some predict an output of 225,000,000 lb. per month inside of two or three months. At present there is a demand for all that is being made, the supply about balancing this. Exports have declined on account of lack of vessels. The question of refining costs is a disturbing one. These have increased through the advance in wages in contiguous industries. It is a question that will demand thoughtful consideration soon, as contracts for refining have not advanced. In response to inquiries for delivery before June 1, producers show an unwillingness to quote.

TIN

There has not been much change in the situation since last week. There is still a pronounced scarcity of sellers, while the number of buyers is large and the desire to buy strong. This has resulted in an advance in prices all around, that is, for future delivery, to 78 and 78.50c. per lb. for future shipment from the Far East for Straits metal. Other brands are correspondingly high. Business during the past week has been small. It has been and still is next to impossible to do business, delay in cables being one of the reasons, also the lack of sellers. Spot tin continues inordinately scarce, with the quotation nominal at 85c., New York. For a 5-ton lot, a higher price has been bid in the last day or two. Deliveries of tin at the Pacific Coast for March are now available. They were 3451 tons, making the month's deliveries 5151 tons. This is larger than for some time, and contrasts with an average monthly delivery of 4140 tons for the five

years previous to 1918. In 1917 they amounted to 4823 tons per month, and in 1913, 3658 tons. Imports for the first quarter were 12,828 tons, against 15,762 tons in this period of 1917. Straits tin accounted for 7822 tons of the 1918 receipts. The total visible supply on March 31 last was 15,887 tons, against 20,307 tons a year ago. These figures indicate the large consumption in this country. Arrivals to April 7 were 170 tons, with 5000 tons estimated as afloat. Spot Straits was quoted at £319 10s. per ton yesterday in London, or £2 higher than a week ago.

LEAD

The market is a narrow one, but while it has declined during the past week, it still contains an element of strength. It has been forced down by lack of demand and has reached 7c., New York, for early delivery in the outside market, with the St. Louis level at 6.90c. There is a decided lack of interest, otherwise 7c. lead would be quickly absorbed. It is a fact, however, that some leading sellers have no metal to offer, and that one large independent producer has shut-down because of labor difficulties. The A. S. & R. Co. has not changed its quotation of 7.25c., New York.

ZINC

The market continues to sag, and apparently has not yet touched bottom, though last week it was thought it could not go lower. Sales of prime Western for early delivery were made today at 7 to 7.12½c., New York, or 6.75 to 6.87½c., St. Louis. One dealer reports a lot of several hundred tons sold yesterday at 7.05c., New York, for early delivery. One large company is quoting 6.75 to 6.87½c., St. Louis. The market is rapidly approaching a crisis, and some say openly that it is to be a battle for the survival of the fittest. While sales have not been large at the lower levels, they have probably been induced by a desire to cash-in. It is a fact that several large producers are curtailing their output considerably. The quarterly report of the U. S. Geological Survey is anxiously awaited.

ANTIMONY

Very little metal is being offered, and demand is also light. The market is quoted at 12.75 to 13c., New York, duty paid, for Chinese and Japanese grades for prompt and early delivery.

ORES

Antimony: No developments are recorded and the quotation is nominal at about \$1.75 per unit.

Ferro-silicon: The high-grade 50% ferro-silicon market is fairly active at \$155 to \$165 for forward delivery, with as high as \$180 to \$190 asked and obtained for spot and early delivery. There are now several new producers of the alloy in this country.

Manganese: Manganese ore imports in February were much larger than expected. They amounted to 56,289 gross tons, compared with 29,796 tons in February 1917. March imports are not expected to exceed 25,000 tons. Ferro-manganese imports in February were only 1417 tons, against 6379 tons in February 1917. Exports were 632 tons, unusually large under the circumstances.

Molybdenum: Molybdenite is nominal at \$1.80 per lb. of MoS₃ in 80 to 90% concentrate. The market is quiet.

Tungsten: An interesting fact is that ore from a British possession in the East was imported in February for the first time. The market has been active, sales of imported ore having been made covering all of 1918 at \$24.50 for scheelite and \$24 per unit for wolframite. Ferro-tungsten is quoted at \$2.25 to \$2.40 per lb. of contained tungsten.

EDITORIAL

WE quote the preamble of the President's recent proclamation: "An enemy who has grossly abused the power of organized government and who seeks to dominate the world by the might of the sword, challenges the rights of America and the liberty and life of all the free nations of the earth. Our brave sons are facing the fire of battle in defense of the honor and rights of America and the liberty of nations. To sustain them and to assist our gallant associates in the War, a generous and patriotic people have been called upon to subscribe to the Third Liberty loan." The response has been splendid; it only remains to make it overwhelmingly successful in order to prove that the whole people is a unit in standing behind our army, which is now in action and playing an increasingly helpful part in stopping the German onslaught and, let us hope, in preparing for an effective counter-offensive.

THE Webb bill, which has now become law, directly authorizes combinations of manufacturers and sellers, and the pooling of the interests of producers and distributors in this country with respect to international trade. This is intended to meet conditions that are expected to rule in foreign commerce after the War, patterned after the kartel, an officially recognized industrial aggregation for trade expansion.

ACCORDING to good authority, the money spent annually in ready-made women's garments runs to \$2,500,000,000. It is probable that \$1,000,000,000 of that could be saved every year. Now is the time to do it. Here, as in England and in France, not to mention Germany, any true woman ought to be ashamed of spending money on needless adornment when so many are in mourning all over the civilized world. Changes of style are a satire on this pentecost of calamity.

CONCRETE has been applied successfully to the building of ships. This fact is represented by the 'Faith,' the first concrete ship launched in America. We publish a short account of the method of construction and we may add that the shipyard in which the 'Faith' was built cost only \$22,500 in money and one week in time—and time is the principal element in the equation that represents our part in the War. The 'Faith' was launched in six weeks from the day con-

crete was poured into the frames embedding the continuous basket-work of welded steel. It is interesting to note that search is being made for volcanic scoria and porous basaltic rock for the purpose of making concrete of light weight suitable for ship-building.

ANNOUNCEMENT is made that the National Lead Company, of New Jersey, and the Williams Harvey Company, of England, have organized the National Lead Company of Argentina, to manufacture mixed metals in the Argentine republic. This step has been taken at the instance of Mr. Simón I. Patiño, the Bolivian tin magnate, who has acquired a one-third interest in both of the parent companies of this new venture. The leading motive has been the growing market in South America, especially in the Argentine, where the high tariff on alloys has necessitated domestic production.

FIXATION of the price of pyrite at 30 cents per unit of the sulphur contained, has been proposed at a conference between the War Industries Board and the Chemical Alliance. The present price for domestic pyrite at the mills ranges from 28 to 30 cents. It is estimated, on the basis of the existing rate of sulphuric acid manufacture and of pyrite production, that the shortage of sulphur for 1918 will amount to 2,500,000 tons. It is thought that an assured price of 30 cents per unit for two years will encourage the mining of pyritic ores so as to make good a large part of the threatened deficiency.

ON several occasions the attitude of President Irigoyen has led to our questioning whether the Argentine republic might be counted well-disposed toward the cause of the Allies. All doubt of the friendship of that country is removed by the conclusion of an agreement whereby the Argentine surplus of wheat, amounting to 2,500,000 tons, or approximately 84,000,000 bushels, is to be delivered to England and France at a price of \$1.44 per bushel free on board ship in Argentine ports. Thus a large quantity of wheat will reach the consumers abroad at a price scarcely higher than that established by the Food Administration in this country. The United States has accepted concourse in this international arrangement by agreeing to release the coal needed in the Argentine, in so far as such withdrawals may not

prejudice our own industrial operations. The understanding thus reached between the four Governments has been styled most felicitously by Señor Luis M. Drago, the originator of the so-called 'Drago Doctrine,' as "an evidence of political favor to the Allies." President Carranza, please take notice!

FROM Cobalt we hear that the principal mining companies in that Canadian silver region have shown their faith in the slogan 'Food will win the War' by engaging in voluntary agriculture. For example, the Buffalo Mines company has acquired a tract of 20 acres about two miles from the mine with the purpose of enabling its employees to use their leisure time in producing crops, which will be divided among those doing the work. The idea is a good one and we commend it to mining companies elsewhere, particularly in regions more fertile than the sub-arctic waste in which Cobalt is placed. Let the Californian thank God for his climate and plant potatoes!

AMENDMENT of the Pittman silver bill, as made by the Senate Banking and Currency Committee, increases the amount of silver coin to be melted into bullion to a total of \$350,000,000. This will be good news to Utah, Montana, Idaho, Nevada, and the other States that are prominent for their output of the white metal. An assured price of \$1 per ounce for nearly five times as much silver as was produced in the whole United States during the year just past, is a substantial encouragement for the expansion of the industry. There is a sardonic kind of humor in it, however, since necessarily the price is fixed in terms of gold, and the value of the gold dollar, measured by its purchasing power, is only about 54 cents, as compared with market quotations in 1914. Therefore the new legislation will barely restore silver to the position it held four years ago, when the average price was 55.3 cents per fine ounce. Without governmental support the country would have been reduced almost entirely to dependence upon such silver as might have been obtained as a by-product in the treatment of lead and copper ores. As we go to press we learn that the bill has passed both houses of Congress and only awaits the President's signature; meanwhile the quotation for silver has risen to a dollar at New York.

NORMALLY, when silver stood at 25 pence at London, the price of silver in New York was $\frac{1}{16}$ of a penny, or $\frac{3}{8}$ of a cent, less per ounce, because the market for the metal is centred at London and the fractional difference in price represents the cost of transport and insurance. At the present price this difference is doubled. Similarly at the present time there is a difference of about 3 cents per ounce between New York and San Francisco, the higher price on this coast being due to the fact that the cost of insurance against war-risk on shipments from New York by way of London and the Mediterranean route is considerably greater than the same tax on direct shipments to the Orient, say, from San Francisco to Bombay, the latter being the great chief Indian centre of silver

brokerage. The element of time, involving interest on money, also favors San Francisco as the distributing point for the great sink of silver in Asia, now that so many more steamers are running between San Francisco and the Orient, as compared with the Mediterranean route.

COULD anything better illustrate the growth of our national appreciation of responsibility than the development of the nitrate industry under Government control? Truly the country is waking up. Anything the War Department says it needs it will get, and it is now proposing an additional expenditure of \$500,000,000 for more nitrate plants. Compare this figure with the \$20,000,000 appropriated for the purpose two years ago, and consider that the imagination to grasp the needs of actual warfare for perpetuating our democracy has increased, in this instance, 2500%. That is a substantial gain in the education of our officials. It is worth recalling, too, that friends of the Kaiser tried to befuddle the authorities at Washington, telling them gravely that careful experiments should be made in advance of spending so vast (?) a sum as \$20,000,000 on a Government nitrate plant, and they had almost succeeded in splitting the appropriation into parcels, to be frittered away, along with our precious time, in a lot of research work. We were assailed, at the time, by these same Teutonic sympathizers, for publishing the truth, but now the Government is rushing the work on cyanamid plants, and on others in which the Haber process will be employed, following practice that needed no further experimental demonstration, while the War Department is calling for 25 times as much money as was originally appropriated for producing this essential in the making of explosives and of food.

The War Minerals Bill

The legislation proposed for the purpose of stimulating the production of the minerals needed for the War is generally approved by the mining public. Originally the bill was so comprehensive as to cover all ores and minerals, including the principal base metals and the two precious metals; in effect it would have created a central administration for the mining industry comparable with that of the Food Administration in relation to agriculture and live-stock. Any such control of the mining industry as a whole provoked opposition, particularly from those engaged in the mining of copper, lead, and zinc. The bill as amended is much less ambitious, indeed it applies only to the metals and minerals normally imported, it aims to stimulate the prospecting and development of products hitherto sought abroad. The list as it now stands, and as quoted by us last week, represents a small and unimpressive fraction of the output of metals and minerals constituting the normal production of mines in the United States. Briefly, it applies to what may be called the 'secondary' minerals, made of prime importance by reason of our intensified manufacture of guns and munitions, tool-steel, and chemicals, especially

such as came formerly from the enemy countries. It is a measure designed not to stimulate commerce but to aid war; it is an emergency measure. Some of the mineral products needed at this critical time occur in nature usually in small deposits, for example, those of chrome and tungsten; it is necessary not to support but actually to create an industry capable of furnishing an adequate supply of such steel-making ingredients. Before a start can be made to exploit the numerous, but small, deposits of such minerals, it is necessary to assure the prospector and mine-operator that he will find a market ready for his output, and such a market cannot be guaranteed so long as the price is subject to the resumption of importation after the War, the duration of which no man can foretell. In short, a guaranty is required before a start can be made. That guaranty this bill provides. The Government, in the name of the President, is authorized "to purchase any of these necessities for which a guaranteed price shall be fixed" under Section 14, and "to hold, transport, or store, or to sell, dispose of, and deliver the same to any citizen of the United States or to any Government engaged in war" with Germany, "or to use the same as supplies for any department or agency of the Government of the United States." A sum of \$50,000,000 is to be provided for the purpose of putting the Act into effect. The time limit is two years. We hope that this limit will be extended, because it may prove insufficient for the starting and establishment of some of these minor mineral enterprises. The British government enacted similar legislation for a period to extend until two years after the War. This means a minimum of two years, and it is reasonable. The fixing of minimum prices and of the minimum time during which they are to be effective is intended to stimulate the search for necessary war minerals and to encourage the production of them. Manifestly such stimulation and such encouragement will be lacking if the time element is too scant, as, we submit, would be the case if two years should prove to be the maximum, as well as the minimum period; because the last section of the Bill specifies that it "shall cease to be in effect after the existing state of war between the United States and Germany shall have terminated." That, of course, is an event the date of which no man can determine; when it happens, the national emergency will have passed, but if we are to create new mineral industries it is highly desirable that they should be aided until such time as they can compete successfully against foreign competition; in short, we would like to see not only domestic production of war minerals but the establishment, on a sound basis, of mines and metallurgical plants able to furnish as many as possible of the materials previously imported largely from the enemy countries. If we have the resources, why should this country be dependent on foreign sources of supply? Another important matter is that of defining "reasonable" prices. We presume that the administrator to be selected to control this new department at Washington will be a man experienced in mining and aware therefore of the risks inherent to mining. This suggests the question of the profit-tax. If fair prices are

fixed, such prices as will warrant the organizing of new enterprise, will the tax on profits be so heavy as to kill the benefit accruing from the stimulus given by the fixation of price? Risk is inherent to mining; the risk is much greater than in manufacturing, despite all the gush printed by irresponsible promoters, whose money comes not from the ground but from the gullible public. A 50% profit per annum might be wholly insufficient to justify the expenditure incurred in finding a small deposit of manganese or of mercury, for it might be exhausted before the working-capital had been recovered. We do not wish any part of the community to enrich itself immoderately at the expense of the Nation at this time, but if it be the Government's desire to stimulate certain branches of mining it is obvious that a monetary gain must be promised to those willing to incur the risk. The matter in hand is not one of charity, nor only of patriotism, but of business, and it must be faced frankly in that spirit in order that the desired results may be obtained effectively and promptly. Some assurance in regard to taxation therefore is quite as much needed as in regard to prices; the left hand of the Government must act in harmony with the right, otherwise the purpose of the present legislation may be balked. Another decisive factor is labor; any price-fixing must pay due regard to current wages. Mining enterprise has to compete for labor against the demands of the Army and Navy, and against that of the cost-plus-10% contractors operating on Government account. Obviously the continued rise in wages might cancel the benefit, to the mineral-producer, of any price-fixing by the Government. As we said at the start, the sentiment of the mining community is favorable to the proposed control and the intended stimulus; we hope that those interested, producer and purchaser alike, will join hands in expediting this supremely useful departure.

The Zone Postal Rate

Periodicals will soon be subject to a progressively increasing tax that will reach nine times the present rates of transportation.

Taxation takes something from a man after he has acquired it. In a republic the levy is intended to be for his welfare, through protecting him in the opportunity to live, to labor, and to develop the opportunities that lie before him. To a certain extent heavy taxation limits his power of initiative and expansion as an industrial factor, but he must submit to what is necessary to sustain his Government in its paternal duty of guarding him and his heritage from the Enemy. A peculiar merit inheres in a direct tax because a man is conscious of paying it, and is thereby brought face to face with his responsibility as a citizen. It gives him a keen realization of the partnership with the Government that is involved in his being a citizen. Raising revenue by such taxes as the excise and customs duties possesses no educational value whatever; it tends to personal civic irresponsibility and promotes the growth of individual selfishness, both detrimental to patriotism.

It is worth while to note the distinction between the effects exerted upon a nation and the people composing it merely by the means adopted for raising revenue. Good civics is good ethics, and a tax that tends to produce a citizen having a superior regard for his obligations to the State, that tends to give him a sense of strong community interest in the Nation as a whole, is clearly a tax possessed of a desirable ethical quality. A tax that exerts an opposite influence is ethically wrong, and therefore is a national evil. We submit that one of the inherent centrifugal forces in that political association which constitutes the United States is the accentuation of State sovereignty and State loyalty. The Civil War was waged against the South's insistence upon State-rights, and the dominant North failed to republicinize the country when it had the chance. A Frenchman from the south of France may call himself a Gascon, but he cannot find a territorial sub-division in which to proclaim a gasconade loyalty. France, with its 86 departments, governed by prefects appointed by the President, accentuates the centripetal civic forces. We are not arguing for so radical a reform in our system of government, but we do insist that any form of taxation that furthers the sectionalization of the United States is not simply an error in policy but is fundamentally a moral wrong. Whatever we may think of the value of many nations, viewed from the broad standpoint of creative civic evolution, it is an evil for the race to nurture tendencies to separatism where once a people has been gathered contentedly under the stimulating opportunities of uniform national laws and the freedom of domestic exchange. In a nation, first and always, solidarity of interest must be cultivated.

In its inconsiderate haste the Congress of the United States has passed a law, which will become operative on July 1, 1918, that is a tax on national fellowship. It is a law that will promote the isolation of the different portions of the country; that will tend to make men Californians, New Yorkers, Georgians, Texans, Minnesotans, to a degree never known before. Although we once went to war to crush sectional thinking, sectional industrial interest, sectionalism of every kind, now we confront a tax-law destined to split us in our habits of thought and in our scope of industrial enterprise into groups of Northerners, Southerners, Westerners, South-Westerners. We refer to the tax on printed matter. Postage is a form of taxation, but it has been wisely limited in the past to an amount barely sufficient to cover the cost of administration. For the sake of easy communication the public has cheerfully made up the frequent annual postal deficits by special appropriation. Freedom of communication has been appreciated as a vital essential for cementing the people together, for permitting them to exchange ideas, for enabling the man in California to read the papers and magazines bringing to him the point of view of the Knickerbocker or the Quaker, and in turn for enabling the New Yorker and the Bostonian to catch the fresh inspiration of the States that front the Pacific and feel the pulse of an Oriental world. When the postage, under this iniquitous tax, doubles the cost of your

'Atlantic Monthly' or 'Collier's,' when you have to pay \$20 per annum for your New York 'Times' delivered in San Francisco, or an equal sum for the 'Portland Oregonian' in New York city, when your 'Current Opinion' is reserved for those who live east of the Mississippi, and your 'Sunset' never carries its lesson to the dawn on the Atlantic, how the spirit of sympathy and understanding will be smothered between East and West! We even hesitate, as good Americans, when we write the words East and West, or North and South, to capitalize them, but this law will raise them completely to 'upper case.' Exchange of ideas, exchange of the printed page, is like the circulation of the blood of civic unity. We soon forget what our brother in Massachusetts thinks and feels if we do not hear from him; soon, if he loses touch with our intimate life, he becomes more self-centred than ever in his Beacon Hill exclusiveness. Why did our people not understand Mexico nor her revolution? Because of the barrier of language; yet a wiser Congress had tried to diminish the obstacles to communication by a postal reciprocity based on the domestic rates of each country. In time this facility for exchange of letters and of literature would have gone far toward breaking down the idiomatic barrier also. What did a wiser Congress in the past undertake in the interest of a closer drawing together of America and England? It authorized a postal treaty applying the domestic rates for communication across 3000 miles of ocean. These are examples of the same efforts that thinking men have made to associate even separate nations in the spirit of developing brotherhood and co-operation. Once before, when this dangerous undemocratic zone system of postage had been tried, it was abolished by President Lincoln, whose wisdom has been approved by every postal commission since. The present Act was carried in Congress as a rider on the War Revenue Act without being submitted to the Postal Committee; it was rushed through nearly unnoticed by most people, concerned as they have been with the urgent business of war; yet this is not a war measure; it was deliberately planned as a permanent feature of the postal administration. Before its sinister influence can be exerted it should be repealed. It is calculated to throttle the free dissemination of information, to narrow the life of the people in the small eddies of sectionalism instead of sweeping them along in the broad current of nationalism, to encourage regional jealousies, and to weaken our national united resolve, which would expose us the more readily to the wiles of Teutonic propaganda. The increase of sectional spirit lessens our collective power as Americans, and plays into the hands of the Kaiser. If Representative Kitchin, the father of this infamous measure, has not reflected that, in foisting it upon the country, he unwittingly was playing the part of a pawn in the Hohenzollern game, it is time that he realized it and displayed his patriotism by introducing a bill to abrogate it. Let every good American insist that this law be set aside. Let him remember that there stands on the statute book a tax on patriotism that must be abolished, if the country of our fathers is to be preserved one and indissoluble.

Mr. Norris and Minerals Separation

The Editor:

Sir—In an article published in your journal on February 2, 1918, entitled 'Scientific Nominalism and Flotation Physics,' by Dudley H. Norris, it is charged that W. H. Ballantyne, patent agent for Minerals Separation Ltd., had access in the British Patent Office to the provisional specification of the Elmore vacuum patent at the time that he prepared and filed the British application for the basic froth-flotation patent No. 7803, filed April 12, 1905, and the suggestion is that he availed himself of this opportunity in the preparation of the Minerals Separation application. The statements in this regard are wholly false and unwarranted, and as Mr. Ballantyne is now serving his country in Mesopotamia as a major in the British army I think it only fair that I should correct them.

In the first place the Elmore provisional specification for the vacuum process which was filed in the British Patent Office on August 16, 1904, No. 17,816, by Abel & Imray, British patent agents, and which remained in absolute secrecy there until the complete specification had been filed and accepted and passed to issue on October 16, 1905, is a document which does not even suggest any reduction in the amount of oil. The entire text of the document is as follows:

"Processes of separation have been devised which depend upon the circumstances that under certain conditions some of the particles of a finely divided mixture rise or float in a liquid menstuum, while others sink therein.

"Among artificial conditions for bringing about such a separation is mixing a pulp of the finely divided material with an immiscible liquid such as tar or oil, soap or the like, either alone or in conjunction with other substances such as alkalis, acids, air or gas; or generating a gas in the pulp electrolytically or otherwise.

"By the present invention, such processes are improved by conducting them wholly or in part under a reduced pressure. For instance, a vacuum or partial vacuum may be maintained in the separating vessel or chamber.

"In one form of apparatus suitable for this invention the flow of the liquid used in the operation is directed in such a manner as to produce or assist in producing the reduced pressure; for instance, the waste water or tailings of the process may be caused to fall in a closed conduit or to operate a suitable pump."

The complete specification following this provisional

specification was not filed until May 10, 1905. This document contains the first suggestion, and this a very vague one, of any reduction in the amount of oil used. This statement is as follows:

"By the present invention all such [prior] processes are improved, more particularly in the respect that a smaller proportion of the added substance, such as oil or acid, may be used, by conducting them wholly or in part under a reduced pressure."

This document, dated and filed May 10, 1905, was two months later than the invention by Messrs. Sulman, Picard, and Ballot of the froth-flotation process.

Thus the mining public will understand why after this British Elmore vacuum patent and the still later corresponding United States patent (application filed July 10, 1905) had been set up in the answer in the Butte & Superior suit as alleged anticipations, they were stricken from the answer and abandoned at the opening of the trial when I called attention to these controlling dates which demonstrated that they could not by any possibility be treated as anticipations.

The practice of the British Patent Office, with which I am quite familiar, provides that provisional specifications must be preserved in absolute secrecy until they have been followed by the filing of a complete specification and that complete specification has been examined and the application has been allowed or passed to issue. This allowance occurred as to the British Elmore vacuum application on October 16, 1905. When this stage is reached, and the patent is about to issue, both provisional and complete specifications are made public to give an opportunity for opposition prior to the issuance of the patent, and two months are permitted for that filing of such opposition. This is what occurred in the instance cited by Mr. Norris, and his ignorance of the practice led him to make the erroneous statement which he sets forth at large in the article referred to. In a case where the provisional specification is not followed by a complete specification and the application thereby becomes abandoned, the provisional specification remains forever secret unless voluntarily published by the applicant.

The usual purpose of an opposition is to prevent a second patent issuing for the same invention that has been already patented. It is a survival of the old practice of the British Patent Office when no searches were made, and it then provided the only protection to the public against two patents for the same invention. It is still continued as an additional safeguard notwithstanding the fact that searches are now made.

Mr. Norris says that as a result of an opposition filed

against his application by Minerals Separation "it was decided in the British Patent Office that the Norris basic patent did not infringe the Minerals Separation patent." This is wholly wrong. No such question was, or could have been decided. Every inventor who makes an improvement upon another patent is entitled to a patent for his improvement, and that right cannot be taken from him, by opposition or otherwise. He may obtain a patent for his improvement if it has not been previously patented, but his improvement will be absolutely subject to the basic or master patent so long as the basic or master patent is in existence. This is fundamental patent law.

HENRY D. WILLIAMS.

New York, April 5.

[Mr. Williams is chief counsel for the Minerals Separation company.—EDITOR.]

Conditions in Mexico

The Editor:

Sir—Since returning to Mexico I have tried to resume mining, but after shipping about 20 cars of ore, I had to give it up. Between the railroad, the smelter, and the Government, 60% of the gross value of the ore was taken; the remaining 40% just paid expenses. Then came the decree that all gold, even in ores shipped, had to be re-imported within 10 days, which was an impossibility, as we could not get returns from the smelter in less than 40 days. This decree was simply a reprisal upon the United States for having issued an embargo on the exportation of coin. Although Mexico tries to make out that foreign coin is unnecessary, nevertheless, if it were not for the American money in circulation in the country, business would be seriously hampered; and if the Government did not accept U. S. gold coin for dues, it would have to go out of business. The Mexicans do not take into account that the United States can effect such an embargo, and that, as a military move, it was necessary, and not intended as an unfriendly act. Mexico cannot secure even a pin, unless it is imported, since it has no domestic manufacturing, and an embargo of the kind under discussion could have but one result, and that would be detrimental to that country. However, it is claimed it will tend to force the nationals to develop their own resources, and they fail to take into account that it requires time and money to do that.

A short time ago I saw an article in the 'Boletín Minero', an official organ, in which one of the editors took issue with a London paper, which criticized the petroleum tax. He says: "Foreigners and foreign capital are welcome, but they are not necessary." Working on this principle, the main object seems to be to make it so hard for the foreigner, by taxes and discriminations, that he will have to get out, and at a sacrifice. Recently a Mexican engineer told me he had gone to Mexico City for a foreign company to try to arrange for importing funds to meet their daily needs. After threshing the matter over, all he could obtain was the permission to

transport bullion from the West Coast, via Laredo, to Mexico City. When the Department Official was told that it could not be done safely, and that the mine would have to close, the reply was: "We do not care; they will continue work, or we will take over the mine and work it for the Government." This is the animus one constantly finds. Duties, in many cases, are 100% of the original cost; and to this is added a like amount of 'infalsificable' bills; not as an extra duty, but as an easy way to retire that obligation, as was pointed out editorially in the MINING AND SCIENTIFIC PRESS.

The Government recently has promulgated an Indemnity Law. It looks all right; but it simply begs the question. The main requisite demanded of all claimants is that they present receipts. Outside of the railroads, this will mean that there will be no foreign claims to settle. I do not need to explain. The officer who, upon turning his regiment of cavalry into your orchard, horses and all, told you to go to . . . when you protested, would be likely to give you a receipt for damages! You noted in your paper last autumn that denunciations for mining claims, in Mexico, were suspended until the new law should be promulgated on January 1, 1918. That law is not promulgated yet, and the right to denounce claims is denied to the foreigner; but any Mexican can denounce at any time. A mining agent told me that his orders were to refuse the denunciations made by foreigners until the *reglamentos* of the new law could be put into effect, but to accept all denunciations made by Mexicans. The foreigner cannot buy any property at all in the country, except by permission from the Government, which, at times, can be obtained by renouncing all his treaty rights. Within 50 kilometres of the coast no foreigner can acquire title to any property.

The country was threatened with a new deluge of paper money, but the opposition has been so persistent and open that the Government has deferred the date of issue, and is now trying to float a \$100,000,000 loan within its own boundaries, in order to establish the single bank of issue, but the general management of all departments, both Federal and State, has been considered to be so corrupt that this scheme is fizzling also. It is doubtful if \$1,000,000 in real money can be raised in the whole country. The 'bilimique' incident is too fresh in the public mind; and while there is no co-ordinated public opinion, nor the courage of conviction, still the impassive opposition cannot be combatted by the Government, and all internal financial projects are sure to fail.

One would think that the spirit of the people would be to encourage industry, regardless of the source of the capital, but it is not. Here is an instance: The Government has decreed that all water taken from the rivers for irrigation, regardless of the method, shall pay a tax of 5c. per 1000 cubic metres. This ordinarily works out at about 6c. per acre. On one farm operating under a pumping concession the owner, who is an American, was not charged for the water actually used, but on the total amount that could be demanded under the concession. In his case, the tax for this year amounts to 35c. per

acre for irrigation. That is what he paid. Such a thing would not have happened to a Mexican.

There seems to be little hope for the present generation, and it will have to get along as best it can. Mexico's only salvation lies in education. It needs schools, and only common schools at that. To this schooling must be added a thorough training in the Ten Commandments as a bit of necessary fundamental law. Without such moral and ethical training there can be no national advancement, and no civilization. If the Government will drop its reform program and give the country absolute commercial, industrial, and intellectual freedom, if it will establish schools and equitable courts of justice, and encourage rather than impede the national progress, confidence will become re-established at home and abroad, credit will become available, and prosperity will return.

Torreón, Mexico, March 18.

A Suggestion

The Editor:

Sir—I wish to propose, in all seriousness, a new type of specialist. Not that he would be absolutely and wholly new, nor even that he is not already in existence, but that he needs emphasis. The specialist to whom I refer is the social consultant.

The social consultant would be employed by a single mining company, or preferably, by a group of mining companies. His function would be to furnish expert advice concerning so-called labor problems.

There is need for such advice, because the manager, in general, is not skilled in these problems. As mechanical engineer, metallurgist, geologist, he may be expert. But he cannot be an expert in everything. As engineer of sociology he must, and does, admit his lack of qualifications.

There is need for such advice because the labor situation is critical. The fire of revolution has been set. Perhaps it will burn slowly and genially, as we pray it may. Perhaps it will burn fiercely—a terrible conflagration. Either way, the laborer has a new power; the old days are gone and the old methods obsolete. New days have come. New methods are demanded. If the manager is to find them, he must have expert advice.

He must have expert advice concerning the causes of discontent and disloyalty, concerning the problem of union recognition, the problem of industrial (and non-industrial) sickness, the problem of housing and the problem of corrupt administration in labor organizations, and a dozen other matters. Not amateurish, half-hearted, haphazard, or prejudiced advice, but the shrewdest, most sagacious, best considered advice that can be found.

The man to give this advice must, I grant, be exceptional. He must be pre-eminently tolerant, sympathetic, and fair; he must be able to inspire confidence and by that confidence to bind men to his cause; he must be above reproach; he must be a student and a philosopher;

he must be a business man and scholarly—a big man all round.

Such a man would serve, not capital, nor labor, but humanity; for he would act on the only enduring basis of conduct—that of justice.

Men who could do this work can be found. They exist, but they are busy at other tasks. Perhaps they would want a high reward to lay down those tasks for this one. The mining industry would do well to get their services. It could afford to pay a high price.

AUGUSTUS LOCKE.

San Francisco, April 5.

The Minerals Administration Bill

The Editor:

Sir—Permit me to thank you, and through you the author, for the very understanding and constructive contribution on the Minerals Administration Bill by George Warren Tower Jr. to a recent issue of your paper. Mr. Tower has evidently given much thought to the subject.

The details of the bill will doubtless be modified in the House Committee and receive still further modification in passage through the House itself and the Senate, but the essential ideas it is hoped can be successfully carried through both houses of Congress. The great need is the granting of sufficient power and resources to some man eminent in the mineral industry, located in Washington and assisted by an able body of mining men. Second only to the prime duty of all of us to help win the War, this mineral administration's principal duty would be the direction of inevitable governmental interference during the war toward the fostering, rather than the suppression, of our industry. Our committee in its original draft of the bill endeavored to gain this protection for all the mineral industries, but the principal metal industries, such as those of iron, steel, copper, lead, and zinc, have not as yet been sufficiently aroused to the ever-increasing disadvantages under which they will be compelled to work while the War continues. Their indifference, and in some cases opposition, where support is essential, has necessitated limiting the bill now before Congress to the minor minerals.

In the case of such minerals as pyrite, manganese, and chromite, the necessity for immediate fostering is so obvious to the producers that (granting we can get our profession aroused to enthusiastic support) there is excellent chance that this modified bill can be passed in some practical form. This done, and a satisfactory minerals administrator appointed, it is hoped that the principal industries will come to realize the advantages this administration might be made to have for them and see to it that they are included in the protection thus afforded before too great damage is done.

The War has already compelled drastic steps in governmental control over such essentials of industry as labor, transportation, and supplies (particularly imports), and practically complete governmental control will be upon us at no very distant date if the war experi-

ence of our Allies is any guide. In the labor situation we already have millions of men being drawn into military service, while other millions are being employed by 'cost plus 10%' and 'rush regardless of cost' Government contracts that have absolute command of the labor market as against normal industries. Again, the Government's recent large-scale labor-housing undertaking will shift labor centres of gravity away from industries failing to receive proper consideration. The embargo on transportation, both of our supplies and our products, is requiring ever more careful attention and supervision. Imports either already are or shortly will be limited to the barest necessities and the mineral industry must be prepared in advance either to furnish its own needs or to see to it that its indispensable imports are maintained.

The power back of these forces is indicated by the size of the loans the Government is being obliged to call for. With billions of dollars being raised every few months for expenses wholly abnormal and solely for the destructive purposes of war, is it not futile to expect that ordinary conditions will prevail in the mineral or any other industry? Even the largest and most highly organized of our mineral industries cannot of themselves expect to properly meet these forces. Patriotism and self-interest will have to combine to unite large and small in shaping themselves to these war compulsions and to seeing to it that there is an adequate mineral administration in Washington with which they can co-ordinate and through which they can as far as possible turn these compulsions to constructive rather than destructive action on our industry.

WILLIAM YOUNG WESTERVELT,

Chairman War Minerals Committee.

New York, April 8.

War Minerals

The Editor:

Sir—In connection with the Government's tentative proposal to assume control of the production of needed war metals, would it not tend greatly to speed up the discovery and production of such deposits if this new Bureau of Metals would, through the publications of the country, officially appoint as a committee of one, every mining engineer, prospector, miner, or other engaged in the mining business, to bring to the attention of this Bureau all deposits of molybdenum, chrome, etc., that they may find? I take it that the needs of the Government for these essential metals will supersede the customary financial question of a profit from their production, and that it is imperative that this urgently needed production be obtained, even though it entails a pecuniary loss in the operation to the Government. If this assumption be correct, it will at once bring to the mind of many mining men the recollection of one or more deposits of some of these metals that ordinarily will not pay to operate, but which can produce a certain amount of needed metal for war purposes.

The number of such deposits, while not legion, is large,

and their combined production would materially increase the spare stocks of metal on hand and go far toward alleviating the present distressing stringency in some of them.

F. H. MITCHELL.

San Francisco, March 28.

[Any mining engineer, prospector, or miner that knows of a deposit likely to yield any metal or mineral required for the War should communicate with the State Mineralogist or with Mr. W. Y. Westervelt, chairman of the War Minerals Committee, at Washington. We discuss this subject in the editorial department.—EDITOR.]

Flotation Royalties

In its report for 1917, the American Zinc, Lead & Smelting Co. says: "It will be noted from the profit and loss statement that a settlement was effected with the Minerals Separation North American Corporation for alleged infringement of their flotation patents at your Tennessee and Missouri operations by paying the sum of \$250,000 and agreeing to become a licensee of the Minerals Separation Company. The technical staff of your company developed the process which is now being successfully used in treating Mascot ores after tests by the Minerals Separation Company had indicated that their process as then conducted would not give commercially satisfactory results, but the Supreme Court decision of December 1916, in their favor in the case of the Minerals Separation Company v. Hyde, was so broad that in spite of the fact that it was only the improvements made by your employees which made the use of the flotation process feasible on Mascot ores, your counsel advised that the operation probably infringed their basic patents and recommended a settlement, which was arranged."

LUMBER PRODUCTION in the United States in 1917 was 39,200,000,000 ft., a decrease of 2% compared with the cut of 1916. This is an estimate made by the Forest Service based on incomplete reports received up to February 26, 1918. Oregon led with a cut of 3,208,000,000 ft., followed by Louisiana with 2,726,605,000 ft.; Mississippi with 1,204,788,000 ft., California with 1,174,326,000 ft., and Texas with 1,009,227,000 feet.

EARTH-SLIDES may be stopped by sub-drainage, according to George L. Dillman. He says "there never has been a slide that could not be cured in this way." Slides are due primarily to water-pressure. Relief of the pressure by sub-drainage ends the difficulty. The slides at Panama might have been remedied by early application of this well-known method.

ICHTHYOL has been found in the oil from the wells on the Warm Springs dome in the Big Horn basin, Wyoming. The oil contains 3 lb. per barrel, and the ichthyol, after refining, is worth \$4 per pound. The only other oilfields in the world that hitherto have reported this valuable drug are those of Rumania.

Flotation of Semi-Oxidized Silver Ore

By E. J. ATKISON

*About a year ago a pronounced effort was made to adapt the process of flotation to Mexican silver ores. This was caused by the high price of cyanide. Since cyanide can now be obtained at a more moderate figure the new process has become less inviting. Few of the companies met with much success. The Santa Gertrudis, Real del Monte, and Amparo companies have no doubt done the most work on flotation. According to the report of the Department of Mines of Mexico the extraction at both the Real del Monte and the Santa Gertrudis was about 50% of the total gold and silver, but I was informed later by representatives of these two companies that an extraction of about 85% was expected after making a few minor changes in the flow-sheets.

The Amparo Mining Co., at Etzatlán, Mexico, in the preliminary work used one K & K machine (type 2612) as a 'rougher,' and a Callow cell as a 'cleaner.' The Callow cell was constructed of wood by Mexican carpenters, while the K & K was a factory-made machine. A battery of 10 stamps crushed the ore to 20-mesh. The pulp then passed to a Dorr classifier, the overflow going to the K & K, and the coarse product to a Krupp tube-mill. The tube-mill discharge was returned to the classifier, so that the feed to the flotation-mill consisted of 90% minus 150-mesh material.

Sodium sulphide at the rate of one kilogramme per ton was used for sulphidizing. A number of different oils and oil-mixtures was tried; G. N. S. No. 5 and G. N. S. No. 22 gave the best recovery. The practice was to add the sodium sulphide and the collecting-oil direct to the tube-mill, and the pine-oil to the classifier overflow. A rough concentrate was taken from the K & K machine and re-cleaned in the Callow cell. The rough concentrate averaged three kilogrammes of silver per ton. The tailing from the K & K was sent to two settling-tanks, where a small amount of lime was added, the clear water being pumped back to the battery. The pulp varied between 8 and 15% solid. On account of the water necessary in the battery it was impossible to keep a dense pulp without thickening. In this test 748 metric tons of ore was treated, giving an average recovery of 72% of the silver and 85% of the gold. The heading assayed 376 grammes silver and 8 gm. gold. Cyaniding the flotation tailing was tried, and it gave an extraction of about 50% of the silver, or a total of 86% of the silver and over 90% of the gold. This was about equal to the results obtained in the cyanide plant at that time, but it took as much cyanide to extract the 50 odd grammes of silver

in the flotation tailing as it did to extract 320 gm. of silver in the cyanide plant. It was also noticed that the solution fouled quickly when treating the oily tailing.

The concentrate from the Callow cell averaged 15 kg. silver, 380 gm. gold, 16% lead, 9% zinc, 5% manganese, 20% iron, 4% lime, and 16% silica. A great deal of difficulty was experienced in handling the concentrate. No filter was available, but the concentrate was settled in the four 'pilas' (3 by 4 by 7 ft.). When a 'pila' showed concentrate within four inches of the top, the flow was diverted from it, the concentrate was allowed to settle for a few hours, and then sacked.

Following this test an effort was made to thicken the pulp in a Dorr thickener before flotation. The pine-oil was added direct to the K & K machine, but the flow-sheet otherwise remained the same as in the previous test. So as to be able to get a thickened pulp, 8 kg. of lime per ton of ore was added in the battery-bin. The result was disastrous. A voluminous froth that carried a very small amount of concentrate appeared on the flotation machines.

The concentrate coming from the cleaner-cells assayed only about 3 kg. of silver, the recovery being 50% of the silver and 55% of the gold. The lime was poorly burnt, thus accounting for the amount used. As soon as the addition of lime was stopped the machines started to produce the proper froth. An analysis of the lime was made to see if the cause of the trouble could be detected. As stated before, previous to this time it was the custom to add lime to the flotation tailing for settlement and pump back the clear water. The return-water carried about 0.25 kg. of lime (CaO) per ton, and for 12 hours each day only the return-water was used in the battery.

Analyses of lime

	%	%
SiO ₂	29.5	29.6
Fe ₂ O ₃	5.4	10.7
Al ₂ O ₃	3.5	3.2
CaO	41.3	38.5
MgO	1.8	1.5
Mn	less than 1 %	
CO ₂	considerable amount	

The froth produced at this time reminded me of that obtained when experimenting with some lead-carbonate ores. These apparently sulphidized nicely, but a recovery of about 50% was all that could be obtained. In almost every case where the recovery was low a voluminous froth appeared. The conclusions reached after the first series of tests were that:

1. Sulphidizing was indispensable with the oxidized ores.

*This work was performed under the supervision of J. H. Howard, general manager, and William Howard, assistant general manager for the Amparo Mining Company.

2. Fine grinding was essential to free the mineral.
3. Two machines in series were necessary, in order to increase the recovery.

4. The density of the pulp must be 4 or 5:1.

5. Raw lime added ahead of flotation was detrimental, but enough lime to promote settling could be obtained by adding it to the flotation tailing and then pumping back the clear overflow.

While waiting to install another K & K machine and re-arrange the flow-sheet a series of experiments was made in a Janney testing machine. It was found early in the work that a good extraction could be obtained by adding sulphuric acid to the pulp. However, the amount required, namely, (40 kg. per ton) was prohibitive. Gasoline was tried, and was found to be as good a flotation assistant in this case as acid. How the gasoline works is doubtful. The idea was that the gasoline cleaned the oxidized mineral and allowed the sodium sulphide to act upon it.

Assuming this to be the case, gasoline was added to the pulp in the proportion of 4:1 first and was then agitated two minutes in the Janney machine before adding the sulphide of sodium and the oil. Too much emphasis cannot be placed on the use of gasoline in flotation. With lead, zinc, and copper, and with graphite, the re-

	Period A		
	Heading	Tailing	Recovery

Silver	334	53	84.1
Gold	5.6	0.6	89.3
Total	85.9

Oil used: G. N. S., No. 5, 0.1 kg. per ton, plus G. N. S., No. 22, 0.3 kg. per ton.

Sodium sulphide: 0.8 kg. per ton.

Pulp: dilution, 18% solid; fineness, 90% - 200 mesh.

Assay of concentrate: silver, 12.035 kg.; gold, 240 gm.

Wilfley table concentrate: 926 kg., assaying silver 776 gm. per ton; gold 14 gm. per ton.

Tonnage: 40 tons per 24 hours.

During period A the entire load was thrown on one K & K machine for three days. This brought the recovery down somewhat. The froth from the No. 1 K & K machine assayed about 6 kg. of silver per ton, while the froth from No. 2 was a trifle over one kilogramme.

sults in most cases were as good as when acid was added.

One thing is noticeable in these, as well as in all the other tests, namely, that the gold floats more readily than the silver. These experiments were conducted under as nearly the same conditions as possible and each experiment represents the average of three parallel tests.

The final test was divided into two periods. During period A 310 tons was treated, and during period B 204 tons. The flow-sheet is shown in the accompanying diagram. While treating the last 514 tons more oxidized ore than usual was drawn from the upper levels of the mine. This was much better from an experimental point of view, for the sulphides float readily. The Wilfley table acted as a pilot.

Pulp: same as in test A.

Assay of concentrate: silver, 12.671 kg.; gold, 232 gm.

Wilfley table concentrate: 806 kg., assaying silver 859 gm. per ton; gold 18 gm. per ton.

COST OF FLOTATION V. CYANIDATION. To simplify the calculations, let us consider the recovery the same by flotation as by cyanidation, although the extraction by cyanide is a trifle better. The cost of freight and treatment on one ton of concentrate is \$19.22. From this would be deducted the premium on the lead, which would be about \$5. The cyanide plant now produces one ton of concentrate per 24 hours from the sand and slime tables. A 300-ton all-flotation plant would have an output of about 7 tons of concentrate per 24 hours. Flotation costs in the mill would amount to 95c. per ton, while

includes the cost of fine grinding, chemicals, labor, water, repairs, and minor items. Another charge of \$2.46 per ton covers the cost of marketing the concentrate, taxes, and a loss of 5% of the silver and gold, as the smelter pays for only 95% of the assay-value. This makes a total cost of \$3.41 per ton.

Cyanidation, when the value of cyanide at the works is 75c. per kilogramme (34.1c. per lb.), costs \$3.92 per ton, which includes the cost of marketing the bullion and other expenses. This leaves 51c. per ton in favor of flotation. Cyanide at a normal price of 35c. per kg., with an extraction 1% higher by cyanidation, would more than make up the difference. There is also the interest and depreciation on the flotation plant to deduct. To

then be cupelled, producing fine gold and silver bullion, and litharge. A market for the litharge would have to be found. The consumption of cyanide on the raw ore amounts to three or four times the silver content. If the heading averages 300 gm. silver the cyanide would amount to about one kilogramme per ton. This ratio of cyanide to silver holds true in the flotation concentrate. The experiments showed that a 12-kg. concentrate would require about 45 kg. cyanide. It was noticed in cyaniding the concentrate that the gold went into solution much more readily than the silver. The heavy collecting-oils retard the cyanidation materially. A gasoline wash before cyaniding is quite effective. Since it required practically the same amount of cyanide to treat the flotation concentrate as it did to cyanide the ore, the question of cyaniding the flotation concentrate puts one where he was in the beginning as regards the cyanide.

Tests Showing Effect of Oil

Pine-oil	0.3	70	-150	87	89
Pine-tar	0.3	72	-200	86	87

The heading assayed silver 326 gm. and gold 7 gm. In all of the experiments 100 gm. of ore was taken, 300 cc. of water, and a small amount of CaO. The oil used was equivalent to one kilogramme per ton. The cyanide consumption was practically the same in all the tests. The ore, oil, and water were mixed for five minutes in the Janney testing-machine before the cyanide was added.

LITHOGRAPHIC STONE is being actively developed at Brandenburg, Kentucky, according to the U. S. Geological Survey. The foreign supply having been shut off it is important to utilize such domestic resources as may be available. Even in a good quarry of lithographic stone the high-grade blocks obtained represent but a small fraction of the total material broken, but the culls can be used by crushing for concrete construction and by grinding for agricultural purposes, a demand that is steadily growing. Lithographic stone is very uniform in quality, containing less than 4% silica, rarely as much as 0.5% alumina, and from 44 to 52% lime (CaO). Being non-crystalline it grinds readily, and is a desirable material to use in making a 'mix' for cement manufacture.

CONCRETE depends for its strength upon securing the highest possible density. With a given aggregate and the same quantity of cement the strength of the concrete reaches its maximum with the smallest quantity of water that can be used to produce a plastic mix. Any increase in the amount of water is accompanied by a rapid decrease in the strength of the concrete.

FLOW-SHEET FOR FLOTATION OF SEMI-OXIDIZED SILVER ORE

make the change from the present plant to an all-flotation mill would cost about \$40,000, including the necessary re-grinding machinery.

The success of flotation seems to be determined by the treatment of the concentrate. If a supply of Mexican crude oil could be obtained at a reasonable figure, it would be a simple matter to install a small roasting-furnace, and, after roasting the concentrate, to melt it in a reverberatory furnace. The base lead bullion could

Sacramento Hill Disseminated Copper Deposit—II

By COURTENAY DE KALB

In the office of the geological department of the Copper Queen mines the records of the drill-sampling of the disseminated deposit in Sacramento hill are reduced to objective representation by means of two separate and unlike models. One of these consists of wrought-iron posts $\frac{3}{8}$ in. diameter, each painted in shades indicating an assay-value lying between narrow limits of a fixed maximum and minimum. The posts are screwed into holes in a $\frac{1}{4}$ -in. iron plate spaced so that the diameters of the posts and the distances between them are in the true proportions to the diameters and distances apart of the actual holes. The tops of the posts above the base correctly reproduce the topography. Sheet-metal cut into proper strips is used to denote the ramifications of the underground workings. Thus at a glance the position and size of the orebody are visible, as also the variations in richness and outline. Another model, however, which is less easy to keep up to date, presents the leading features even more vividly. This is painted in transparent colors on automobile wind-shield glass plates set one inch apart, the surface being shown on each plate. The model is sustained in an open-work frame, so that it is completely transparent and can be viewed from every side. It is unlike most glass mine-models; not only is the orebody seen with the details in their proper relations, but it appears like a luminous cloud suspended in a clear medium, so that its every feature may be examined.

After drilling had proceeded for a short time what seemed like erratic variations in the depth to the ore provoked uneasiness regarding possible difficulties of mining the deposit. This was before the peculiar form of the orebody had been determined. As data accumulated the outlines on the model grew into a well-defined figure. The first impression that it produces is that of outstretched wings above a bulky body having a somewhat rounded shape. J. B. Tenney, the geologist in charge, compared it to a mass that had been eroded into a valley. The accompanying cross-section gives only part of the effect obtained when looking at the model; the trough is seen, but the rim on the left is thinner than the average. What the section does show, however, is the vagaries of oxidation; a re-entrant mass near the top projects under a shelf of ore assaying 1.75 to 3.5% copper; below this is a large mass of oxidized waste, with the 1.75 to 3.5% ore above, and a considerable thickness of 1.3 to 1.75% ore directly underneath, the high-grade (above 3.5%) persisting as the core of the main volume of ore, and being surrounded by leaner material on every side. Those who insist upon playing the porphyry-

copper game according to Hoyle will find trouble with this array of exceptions. As a matter of fact the experienced geologist has learned that the more new ore deposits that are developed the more new principles are discovered.

GEOLOGY. The Sacramento hill deposit has been full of surprises and unique relationships. For one thing, it is not a secondarily enriched orebody; neither is it primary. In appearance the ore bears a general resemblance to the ordinary disseminated porphyry ore enriched by leaching and re-deposition; the copper is present as chalcocite, and largely in the form of the so-called sooty chalcocite, held in a highly sericitized grayish gangue. It proves, however, to be a zone of primary mineralization, altered in place by sulphate waters with very little addition of copper from above.

Returning to the structure of the orebody, Sacramento hill shows a series of east-west fractures. These are approximately parallel to the line of weakness originally developed by the Dividend fault. Otherwise they have nothing to do with that fault, except that they are secondary to it and perhaps were induced by it. They dip in the same direction, that is, to the south. The axis of the East and West orebodies conforms almost exactly to the trend of the Dividend fault. The best defined of these induced fractures in the granite-porphry stock forms a well-marked foot-wall for the West orebody. It is the only wall that has been discovered, and in the underground workings it is seen to be markedly slickensided; that it is a pre-mineral movement is proved by the circumstance that it constitutes a limiting plane for the ore. Some of the other faults in the hill are post-Cretaceous, probably responding to the disturbance due to movements still taking place on the Dividend fault. This great fracture, supposedly originating in later Carboniferous time, or in the early Permian, although invaded by the granite-porphry that was responsible for the mineralization in the Copper Queen property, has not ceased its movement; a normal displacement is proceeding at such a rate as to render it impossible to maintain open drifts in its neighborhood; as a result of the continuance of the faulting movement they close within a year. This movement is increased by stoping. In common with the orebodies of the entire Warren district the longer central axis of the Sacramento Hill masses bears S. 80° E. and inclines south-east. The West orebody 'bottoms' at a depth of 400 ft., and the East orebody at 1100 ft., within a longitudinal distance of 2000 ft. Thus the 'valley' in the orebody would drain in that direction, and its position is further conformable to the plane of

BIG BLAST IN BRECCIA ABOVE THE SACRAMENTO HILL OREBODY

SACRAMENTO HILL, READY FOR THE STEAM-SHOVEL ON MACHINE-SHOP BENCH

the foot-wall, which limits the limestone replacement ore-bodies on the W.S.W. side. Despite the corrosion from oxidation along the central axis, a large part of the valley-wall on the northern side is composed of altered primary ore revealing but little secondary enrichment, assaying above 3% copper, while the wedge-like mass forming the south-west slope is generally leaner than 1.3%. It must also be observed that the Sacramento Hill orebody lies in the porphyry on the side next to the limestones, which is again in conformity with the rule of the district, for the ores lie in the younger rocks on the hanging-wall side, that is, the south-southwest side, of the Dividend fault. The Pinal schist, the Bolsa quartzite, the Abrigo, Martin, Escabrosa, and Naco formations, had been faulted up on the north side, and were worn away during the pre-Cretaceous erosion-period. The granite-porphry stock outcrops much farther on that side of the Dividend fault than it does on the south, but the northern portion is destitute of ore. The porphyry on the north side, however, is thoroughly mineralized with sericite and pyrite, corresponding to the porphyry below the ore on the south side. Any ore which may have existed would have been in the Paleozoic formations, which have been eroded since. This localization is significant; it is one of the characteristics that definitely ties the Sacramento Hill deposit to the same genetic influences as those responsible for the rich accumulations that have marked the history of Bisbee.

An interesting peculiarity of the granite-porphry stock is that it invaded the plane of weakness offered by the Dividend fault but did not spread out and occupy the fault-plane in the form of a dike; it advanced as a mass 5000 ft. long in the direction of the Dividend fault and 4500 ft. wide at right angles, that is, in a northerly direction. It is not a stock of ideal shape, since it is not of rounded horizontal section; it is exceedingly irregular in outline, particularly in its extension toward the north and north-east. It did not enter in a molten condition, nor did it stope its way upward; it was forced up as a plastic mass, and brought with it a marginal load of debris, composed of mixed fragments from every formation traversed, including rounded 'bombs' of the porphyry itself. This fringe is characteristic of the intrusion, and resembles the 'drag' often produced in faulting; locally it is called the 'breccia zone'. The width of this breccia varies from 50 to 1000 ft., and it not only formed a border to the stock, but covered its advancing crown. After erosion of the superincumbent rocks it remained as a capping over Sacramento hill, and it was this that gave to it the peculiar appearance previously mentioned. Alteration has affected it differently from the stock that it enveloped.

Three distinct types of ore are observed at Bisbee, (1) the porphyry ore in the altered stock, (2) contact or primary replacements in the breccia, and (3) normal replacements in the limestone, which extend in places to a distance of 3000 ft. from the porphyry. Mineralization of the granite-porphry took place after consolidation

of the rock, and there is not much evidence of pneumatolysis. The minerals formed at that period are those characteristic of moderate temperatures; even the scanty garnet is of the variety andradite, which develops at a low temperature. There was an original pneumatolytic action contemporaneous with the intrusion, producing magnetite, zinc-blende, and pyrite; and a second at the end of the intrusion, bringing in silica and pyrite, but this was confined to an outlying area, and its effect upon the rocks was small, owing to the low temperature. The outcrop of breccia on Sacramento hill had been silicified; it weathered into dark blocky masses, resistant to erosion. The ground-water toward the end of the pre-Cretaceous erosion-period probably was charged with sulphates of iron and copper and also contained considerable free acid, consequent upon the erosion reaching the contact zone between the porphyry and the Paleozoic rocks to the north of the fault. The erosion of the up-thrown block on the north side apparently kept pace with the oxidation, so that when the contact zone was reached, toward the end of Paleozoic time, the seepage waters took up large amounts of free acid and sulphates of iron and copper. As the north side was high ground, most of this drainage flowed into the depressed area to the south, sank into the rocks, and altered the ores that have now been developed. This probably accounts largely for the fact that the effects of the pre-Cretaceous oxidation and enrichment were so much greater than those of the latest uplift, despite the longer period of this late movement. During the present erosion-period, except possibly at the top of Sacramento hill, no masses of contact material have been exposed on which surface waters could act. Therefore they have been free from acid. The porphyry and the contact-zones have been completely sericitized, but the sericitization preceded the final metallization, while the introduction of the metals in the porphyry represented the expiring phase of primary mineralization in the district. Pyrite, however, was deposited both before and during the period of sericitization. Below the ore-zone the porphyry is sericitized and highly pyritized, but contains only 0.2 to 0.4% copper. The deposition of the copper appears to have been dependent more upon decrease of pressure than upon chemical reaction. The pyrite is quite free from copper, even when embedded in chalcocite, while the primary copper mineral was almost exclusively deposited as bornite. Outside the porphyry ore the more abundant primary copper mineral is chalcopyrite, usually intergrown with bornite, but in Sacramento hill chalcopyrite is uncommon, except toward the outer edge of the deposit. The bornite is usually found replacing pyrite, but it also occurs quite independently of the pyrite. As a whole, however, the porphyry ores, now containing the copper almost completely altered to chalcocite, are unique in possessing an extraordinarily high percentage of pyrite. Mill-tests give one ton of concentrate for every $3\frac{1}{2}$ to $4\frac{1}{2}$ tons of ore, and the concentrate contains from 8 to 12% copper and 30% iron. A noteworthy feature of the pyrite is that the crystals are

graph of what is known as the machine-shop bench, where it has attained the natural slope for broken material. The track is there laid ready for the work of stripping. Above this will be three more benches, 60 ft. apart vertically. The uppermost slice will be worked with a maximum face of 120 ft., yielding 300,000 cu. yd. of overburden. The lifts above the machine-shop bench will be reached by switch-backs, with the exception of the fourth, which will be gained by circling the hill on a $2\frac{1}{2}$ % grade. From the lower three benches the slices will be taken horizontally across the hill. The plan for the tracks on the several terraces, and the tracks for disposal of the waste, are shown in the accompanying plan. Bucyrus steam-shovels will be used for the work of excavation. After shoveling down to the machine-shop bench the next two terraces will be attacked by entering with tracks from the north-west side, 60 ft. and 120 ft. lower, and for the next bench, 60 ft. below this, it will be necessary to gain access through a deep cut past the power-house to the east slope of the hill. From that level the tracks probably will follow a spiral to the bottom. Many structures had been erected around Sacramento hill before it was determined that an orebody lay underneath. Among these was a large well-equipped machine-shop. This has already been removed. The power-house also will have to be moved before the East orebody is mined.

CONCLUSION. Sacramento hill will soon appear in the list of the great producing 'porphyries'. It is a unique property, and will repay attentive study by mining engineers, for they will acquire knowledge from it that may help to guide them in judging and developing other low-grade disseminated deposits of copper. Here is a hill but partly tested in which have been disclosed many million tons of ore, a property that had been under daily observation for 30 years before the presence of economic mineralization received confirmation, or was seriously credited except by a few. Here is an orebody concealed under a cap, the like of which is seldom found, originating from the slow intrusion of a stock of plastic granite porphyry, dragging with it a mantle of fragments torn from the formations traversed, a cap that gave no indication of the treasure hidden beneath it, and when at last it was revealed by exploration, renewed partly in the spirit of eliminating doubt as well as through active hope, it presented a rare and interesting individuality. Normal sulphate-leaching had been absent. Oxidation above did not enrich the material below, and yet the oxidizing copper did not remain; it was largely dispersed and only to a small extent was it fixed by carbonic acid. The familiar type of secondary chalcocite ore in a sericitized gangue is here seen as in so many other disseminated deposits, yet the chalcocite is merely an alteration-product from the primary sulphide; and, contrary to usual experience, Sacramento hill yields chalcocite ore, free from primary or secondary chalcopryite, but in which an extremely large amount of pyrite exists. The geologic doctors have here an interesting 'case', which will soon be exposed for more minute examination.

Ballast

In the days of sailing ships and in the early development of steam vessels, ships could not make voyages without cargo. If, after discharging their freight, no return cargo was available, a load of ballast would be put aboard. This ballast of sand, stones, chalk, etc., usually amounted to one-quarter of the outbound cargo. The streets of Charleston, South Carolina, are paved with cobblestones brought in on ships that loaded cotton there. Around the English ports near the coalfields may be seen great hills of ballast, chalk, etc., brought from European ports to which coal had been shipped. Obviously much delay and expense resulted from the loading and unloading of this ballast. When ships were first built of iron instead of wood, various methods were tried to make the carrying of ballast unnecessary. An iron schooner built in 1856 was the first to adopt double-bottom water-ballast tanks. This is the most successful method yet devised to make sand-ballast unnecessary. About four years later an iron steamer was the first of that class to be so equipped. But along in 1865 double-bottom water-ballast tanks were in fairly general use. These enable ships to carry a weight of water equal to about one-sixth, in most modern ships one-quarter, of their cargo-carrying capacity. This water is held rigid and acts as solid ballast. Deep tanks, peak tanks, etc., are other forms in use additional to the bottom-tanks, enabling ships to carry a weight of water equal to one-fourth to one-third of their cargo capacity. In consequence of the continual development of the water-ballast tank construction ever since the 'sixties there are now very few ships afloat that require stone, sand, or other solid ballast. The rare exceptions are old ships, especially a few Great Lake vessels that are now on the ocean.

This development was a most important one, as trade conditions before the War were such that one-fourth to one-half of the voyages made by cargo ships, especially those not belonging to standard steamship lines, had to be made without cargo. Great numbers of ships continually sailed to all parts of the world with no ballast except water. If this was the condition in normal or peace times, it is still more the case today. In these days when the number of ships is inadequate, it is exceedingly fortunate that there is no necessity for ships to be delayed while loading and unloading ballast, when a voyage must be made without cargo, as happens so often. No more is it necessary for ships to be delayed in loading and unloading cargoes of goods, such as luxuries or non-essential commodities. Besides delay in loading the added weight makes the ship sink low in the water and travel slower, especially in calm weather. Also this greater amount of hull under water is a larger target for German torpedoes.

COPPER PRODUCTION of Chile in 1917 amounted to 83,000 metric tons, against 63,580 tons in 1916.

UTAH possesses an area of 13,300 square miles known to contain workable seams of coal.

Chart for Tonnage-Sampling and Dilution-Control

By HALLET R. ROBBINS

The accompanying chart has been designed to simplify as much as possible the control of mill-pulp dilution, and to eliminate the necessity for any calculations whatever by the operator. Three different kinds of determinations may readily be made by the aid of the chart, namely, dry tonnage per 24 hours, percentage of solid in wet pulp, and specific gravity of dry ore in wet pulp. The formulae on which the chart is based was furnished by R. B. T. Kiliani and are as follows:

1. Dry tons per 24 hours, $T = \frac{1440 \times 62.5 \times V a s}{2000 t}$
2. Percentage of solid in wet pulp, $S = \frac{G(a-1)}{a(G-1)}$
3. Specific gravity of dry ore, $G = \frac{W}{W - (a-1)}$

Where

V = Volume of tonnage sample tank in cubic feet.

a = Specific gravity of wet pulp.

s = Percentage of solid in wet pulp.

t = Time in minutes for pulp stream to flow V cubic feet.

G = Specific gravity of dry ore.

W = Kilogrammes of dry solid in one litre of wet pulp.

The tonnage-sample tank used in the plant for which this chart was prepared measures 22 by 54 in. inside, and it is filled to a depth of $11\frac{1}{8}$ in., which allows for a sample of 1000 cc. to be taken from the pulp stream flowing into the tank, the net weight of which sample in kilogrammes is the a used in the formulae. For this particular tank, formula No. 1 reduces to $\frac{371 a s}{t}$, and the chart is good only for this constant, but a similar chart could readily be prepared for any other constant.

To determine the dry tons per 24 hours, use the first line of figures across the bottom of the chart. Find a point whose ordinate is the observed a and whose abscissa is the observed t . Lay a ruler so as to touch this point and the lower left-hand corner of the chart (the origin). Where the ruler touches the vertical line corresponding to the correct dry specific gravity of the ore being sampled, read the dry tons per 24 hours.

Example 1. Observed $a = 1.18$, $t = 3.5$

G known to be 3.6; $T = \frac{371 \times 1.18 \times 3.6 \times 0.18}{3.5 \times 1.18 \times 2.6} = 26.4$

To determine the percentage of solid in wet pulp, knowing a and G , use the second line of figures across the bottom and the abscissa corresponding to the known ordinate a , and referring to the curve for the known G , is the desired s .

Example 2. Observed $a = 1.18$, known $G = 3.6$

$s = \frac{3.6 \times 0.18}{1.18 \times 2.6} = 21.1\%$

To determine the specific gravity of dry ore in wet pulp, use the third line of figures across the bottom.

Find a point whose ordinate is the observed a and whose abscissa is the observed W . Lay a ruler to touch this point and the origin. Where the ruler touches the line marked 'Dry Ore Specific Gravity Line,' read the desired value of G on the same scale at the left of the chart used for values of a .

Example 3. Observed $a = 1.32$, observed $W = 0.450$

$$G = \frac{0.450}{0.450 - 0.32} = \frac{0.450}{0.13} = 3.46$$

Air-Blasts

The Kolar goldfield, which is situated in the State of Mysore, southern India, is noted for peculiar and violent explosions in the mine workings. These may occur in the quartz vein, or in the hornblende-schist, which forms the bulk of the country rock; or in the dolerite dikes, which cut the vein and the schists. They are most frequent and violent in the quartz, and are due to a strain in the rocks that causes violent fracturing when the potential energy is permitted to act, as occurs when mining operations have removed the supporting rock on one or more sides of a mass. In addition to the minor explosions, which occur at nearly all depths, in shafts, stopes, and drifts, there are heavy shocks caused by the giving way of pillars or other supporting masses of rock, with great rupture. This unusual violence is doubtless due to the fact that the rocks are already subject to internal strain. Several hypotheses have been suggested to account for these explosions, but the only one which, in the opinion of the writer, is adequate, is that the rocks of this field have been subjected to a great compressive force by crustal movements associated with igneous activity, and that the rocks have never been relieved from the resulting strain except near the surface and in local areas in various parts of the mines.—E. S. Moore in Bull. A. I. M. E.

COAL burned in stoves is a wasteful method. During the present stress arising from transportation difficulties, special efforts should be made to encourage the use of gas for domestic purposes. A ton of coal converted into gas will yield a heating efficiency equal to 2400 lb. burned on a grate, in addition to which it will yield about 1000 lb. of coke, 14 lb. of benzol, 18 lb. ammonium sulphate, 20 lb. of heavy oils, and 2 lb. of phenol.

CHEMICAL imports into the United States in 1917 were valued at \$144,235,400, against \$125,813,205 in 1916. Value of exports was \$193,255,160, an increase of \$27,969,152. Acid accounted for \$52,695,640. Sulphuric acid amounted to 31,771 tons, a slight decrease. Dye-stuffs increased from \$7,953,986 to \$16,107,361.

PETROLEUM DEPOSITS are being developed in the State of Alagoas, Brazil, not far from the coast. Oil is also reported from the interior States of Matto Grosso and Goyaz, and exploration of these deposits is also being made.

CHART FOR TONNAGE-SAMPLING AND DILUTION-CONTROL

THE 5000-TON CONCRETE SHIP 'FAITH'

Designing of Concrete Ships

By L. R. FERGUSON

*In designing a ship, it is assumed to be supported in two ways, first, for 'hogging,' and second, for 'sagging.' That is, the wave in one instance is supposed to support the ship in the centre, with the ends unsupported. In the second case, the ship is supposed to be supported at the bow and stern on the crest of the waves, the trough of the wave being under the centre of the boat. These waves are supposed to have a height equal to $1/20$ of the length of the ship. Considering the ship as a beam, this produces alternate tensile and compressive stresses in both the top and the bottom of the structure. This governs the design of the ship as a longitudinal girder.

The ship must also be designed so that the sides and bottom will resist hydrostatic pressure. For this a system of transverse members called frames is provided. The accepted method of designing the frame is to consider the frame as a ring and to use the ring formula. This corresponds to the elastic-arch theory. Even with the supports fixed, the design of an elastic arch is not simple. With the concrete ship nothing is fixed. We must go through a long process to determine the position of the neutral axis in different parts of the frame, under the various conditions of external force that must be considered.

Around the frame is the shell. This has two functions to perform besides the primary one of keeping out the water. First the side may be considered as a sort of floor-slab, the load being the hydrostatic pressure that is distributed to the frames or transverse members of the ship.

This is a comparatively simple matter, for the frames can be spaced to obtain the desired span. In addition to this, however, the shell acts in the same way as the web of a box-plate girder. The analogy can be carried further, the boat-frames can be considered as the stiffeners, and the deck and bottom of the boat as the flanges. The most important factor in designing the shell is the shear at the quarter-points. In this connection some interesting problems must be considered. For instance, do the frames increase the shear-section, and if so, to what extent? Does the bending of the vertical reinforcement of the shell into the bottom and deck anchor these rods sufficiently to produce the same effect as rigid attachment to the longitudinal reinforcement? Probably the most important question is the effect of alternate tensile and compressive stresses in the longitudinal members.

Let us now consider some of the advantages of the concrete ship. Such consideration must be governed by present conditions, although some of these conditions will continue after we have won the War.

The material to be used in building concrete ships is plentiful and widely distributed. It is not used for ships now being constructed, so there will be no interference with present programs. The class of labor to be used for the concrete ship is different from that used on either the wooden or the steel ship, and is mostly unskilled. Above all, the speed with which concrete ships can be built is of the utmost importance.

The maintenance cost of a concrete ship will be small, although the idea, held by many engineers, that barnacles will not adhere to concrete is erroneous. This, however,

*Extract: American Society of Marine Draftsmen.

can probably be overcome, and, at any rate, conditions will not be worse than for a steel ship.

The original cost of a concrete ship will probably be considerably less than steel or even wood. The resistance of concrete to fire is an important consideration. The shape of steel and wooden ships is governed to a considerable extent by the characteristics of the material used. With concrete, however, we can make the bow and stern conform to any conditions. The steel in the concrete ship can be placed where it will do the most good, whereas in both the steel and the wooden ship the efficiency of the material is often reduced considerably by the necessity of making joints.

One of the objections frequently raised against concrete for ship construction is that the weight of the material is too great. As a matter of fact, the weight of the hull of a concrete ship will be little, if any, more than that of a wooden ship of equal carrying capacity. The disintegrating effects of salt water on concrete is another objection. This, however, can be prevented by proper methods of protection. The possibility of corroding the reinforcing-steel is more serious. The investigations of marine structures conducted by R. J. Wig and myself showed the danger of cracking where reinforced concrete is exposed to moist sea-air, provided ordinary construction methods are followed. This too can be overcome by observing proper precautions.

The First Large Concrete Vessel

On March 14 the 5000-ton reinforced concrete ship 'Faith', built by the San Francisco Shipbuilding Co., was successfully launched at Redwood City, California. While a number of barges and a few small self-propelled vessels have been constructed of concrete this is the first large ship to be built of this material. It was designed and constructed by Macdonald & Kahn of San Francisco.

The vessel is 336 ft. 3 in. over all, the length between perpendiculars being 320 ft. The beam is 44 ft. 6 in. and the molded depth is 31 ft. The draft is 24 ft. With this draft the carrying capacity will be 5000 tons. The empty hull draws 9 ft. of water. The concrete in the hull is from 4 to 5 in. thick. There are five concrete bulkheads. The bow is reinforced with a $\frac{3}{4}$ -in. steel plate. The reinforcing-steel used in the hull weighs 550 tons. The main deck is of wood resting on concrete stringers. There are three cargo-hatches. About 2,000,000 ft. B.M. of lumber was used for the forms, of which about 10% can be used again, assuming a similar design.

Work was commenced September 1, 1917, and the first concrete was poured October 31. The last concrete was poured February 26, 1918. A water-proofing compound was used in mixing the concrete. The concrete was kept wet for three weeks after pouring, but it is evident that this rule was not strictly observed, since the vessel was launched 16 days after the last

concrete was poured. A heavy black asphaltic paint was used on the outside of the hull.

The estimated cost of the empty hull is \$450,000 and of the completed vessel, \$890,000. The vessel will be

WELDING REINFORCING-BARS.—VIEW OF INTERIOR OF VESSEL

equipped with reciprocating engines developing 1760 horse-power. It is expected that the speed will be ten knots per hour. The vessel will be equipped and ready for service about June 1.

MOLDING SAND is formed as flood-plain deposits and as re-washed ancient beach-sands, that is, it is produced where there is a mingling of detritus from argillaceous deposits and rocks yielding sand, becoming intermingled under conditions permitting of their being worked over by water during which the excess of clay is carried off. The ancient beaches of glacial lakes are most favorable, and molding sand is often found at the lower levels of such deposits. Argillaceous sandstones and some decomposing granites, on being crushed, will sometimes yield a desirable grade of molding sand, and it may be prepared by mixing fine sharp sand or finely crushed quartz with a suitable quantity of clay.

Minerals Separation and Beer, Sondheimer & Co.

The following question and answer were made in the House of Lords on March 13, 1918, according to 'The Times'.

LORD SYDENHAM asked two questions concerning a German firm: (1) Whether the American branch of Messrs. Beer, Sondheimer & Co. of Frankfort, was black-listed and subsequently released; and (2) what conditions were imposed when this branch of the German firm was permitted to act for a time as agents of Minerals Separation American Syndicate.

LORD HYLTON, who replied, said the information which the Government had was to the effect that Messrs. Beer, Sondheimer & Co., of New York, were included in the statutory list, generally called, he thought, the black-list in the United States, in July, 1916, and remained on that list until it was withdrawn on the entry of the United States into the War. It is perfectly true the Minerals Separation American Syndicate (1913) (Limited), which is a British registered company, entered into an agreement in the month of September, 1913, with Messrs. Beer, Sondheimer & Co., under which the firm were appointed the sole agents of the syndicate for the transaction of all commercial affairs of the syndicate in the United States of America, Canada, Mexico, Cuba, and the Philippine Islands. Messrs. Beer, Sondheimer & Co. have their principal office at Frankfort, and have a branch in America carried on by Messrs. Benno Elkan and Otto Frohmknecht, who were resident and domiciled in New York City. In October, 1914, the syndicate applied to the Committee on Trading with the Enemy for leave to enter into an agreement with Benno Elkan and Otto Frohmknecht, under which the syndicate appointed them as the American branch of Beer, Sondheimer & Co., its sole and exclusive agents for the transaction of the commercial affairs of the syndicate in the places already mentioned, and Elkan and Frohmknecht undertook not to pay or cause to be paid any money, etc., arising from or in connection with their trade relationship with the syndicate to Beer, Sondheimer & Co., of Frankfort, or any person resident in Germany or Austria, or to anyone for the use of such person during the War, and to defer until after the War any commission or remuneration payable to them. At that time Beer, Sondheimer & Co., of New York, were not black-listed, and no authority was required by the syndicate to enable them to enter into the proposed contract. They were informed by the Committee that there was no objection to their doing so.

In June, 1916, the syndicate approached the Treasury again. In view of their difficulties in America they had been advised to form an American Corporation to acquire from the syndicate the United States patents and the patents for Canada, Mexico, etc., and all their assets and other rights, but they were prejudiced by the agency agreement entered into with Benno Elkan and Otto Frohmknecht, the American corporation which was pro-

posed being unwilling to submit to the obligation to deal with them. The syndicate, therefore, proposed to invite Elkan and Frohmknecht to cancel the agreement in return for a certain number of fully-paid shares in the company and an option to subscribe at par for further shares. The shares in question were ultimately to be converted into shares in the American corporation, and no benefit was to accrue in respect of them for five years. The substitution of a moderate share-holding interest in the company—£17,500 out of £200,000—appeared to be preferable to the control resulting from the exclusive agency under the agreement of 1914, and, after reference to the Board of Trade, the syndicate's proposal was sanctioned, subject, of course, to the approval of the Capital Issues Committee of the issue of shares if a new issue was involved. Meanwhile the syndicate received from America the agreement entered into there for the formation of an American corporation for the acquisition of its undertaking and assets, as finally settled. This agreement necessitated a modification of the proposed agreement with Elkan and Frohmknecht, putting an end to their exclusive agency. The shares which they were to receive as consideration for cancellation were to be placed at their disposal at the end of the War instead of at the end of five years, and Elkan and Frohmknecht were to be the general agents in the countries which I have mentioned, although not the exclusive agents, of the American company. On the other hand, they released to the British company the money to which they were entitled in respect of commission, which was stated to amount to from £16,000 to £20,000. The company stated that it was absolutely essential to continue this provision as to the agency, Elkan and Frohmknecht absolutely refusing to assent to its cancellation, and they pointed out that a leading American counsel had advised, in America, that the American branch of Beer, Sondheimer & Co. had no authority to enter into the new agreement or give the guarantee as to no-enemy benefit, and that the original agency agreement of 1913 was still in existence and could be enforced against the syndicate in the American courts. Meanwhile the name of Beer, Sondheimer & Co. of New York had been added to the statutory list. In all the circumstances the Treasury came to the conclusion that it was advisable in the national interest to authorize the company to enter into the agreement of August 4, 1916, with Elkan and Frohmknecht even though their right to be appointed agents remained, rather than to leave the company under their liability of the 1913 and 1914 agreements to employ them as sole and exclusive agents, and sanction was accordingly given, so far as the Acts and Proclamations relating to Trading with the Enemy were concerned. The Capital Issues Committee subsequently recommended the issue of fresh shares, out of which *inter alia* the shares to which Elkan and Frohmknecht were entitled were allotted to them.

ZINC CHLORIDE is in good demand at the present time, with prices ruling steady at about 10½c. per lb. for prompt delivery.

Safeguarding Industries From Enemies Within

The National Americanization Committee makes the following recommendations to those in charge of industrial establishments:

1. Personnel Census and Current Registration. Take a census of the personnel and keep thereafter a current registration, dividing all workers into six groups: native-born, naturalized, first papers, second papers, alien enemies, all others. All subjects of the Central Powers as well as all other aliens without first or second papers, including both men and women, should be classified as of 'doubtful loyalty' from a safety viewpoint.

2. Plant Analysis. Make an analysis of the physical conditions of the plant, then chart or map the location of the vulnerable plants, noting particularly places where fire and explosions will do the most damage, where lights are important, where switchboards are placed, and where water-supply hydrants are located. The location of indispensable and delicate machinery which can be easily injured and is difficult to replace should also be noted. Include in this analysis the routing of products to local shipping-points to ascertain where they can be most easily tampered with.

3. Distribution of Employees. Ascertain how each vulnerable spot is protected and how it is manned, and then gradually shift into these places only native born men and women, who are in sympathy with present war policies. They should receive the best possible rates of pay. Their loyalty is your safeguard.

4. Surveillance Guards and Sentinels. Provide only those of native birth and place them in accordance with the results of this analysis, both as to the plant conditions and the distribution of employees.

5. Watchmen. Secure only those of native birth, vigorous and intelligent men, pay them the best possible wage rates and constantly remove all causes for dissatisfaction.

6. Permits for Workmen. Do not issue a general tag or number to foreign-born workmen which entitles them to visit at will different departments of the plant. The man who can do little damage when scientifically placed may be a good risk, but may prove dangerous if allowed to roam about the plant. Place restrictions on bringing packages into the plant and locate lunch-rooms away from danger zones or vulnerable spots.

7. Admission to Visitors. Require credentials and verify them, and see that visitors are permitted to go only to the places intended. Escort them in, stay with them and see them out.

8. Labor Turnover. Decrease the labor turnover in every possible way so as to keep down the number of new men and women taken into the plant. Find out as much as possible about all new employees and keep the information up to date.

9. Americanization Deputies. Appoint some employee as an Americanization captain who understands the

alien. Give him a committee of leaders of the foreign-born if he wants one. It will be his duty to get in touch with the foreign-born employees, take some interest in them, see that they get the information they seek on registration, the draft, the interpretation of Government orders and other questions that come up. It will pay to keep close to the foreign-born employees and help them to get the right information.

10. Anti-American Activities. Remove as promptly as possible every cause or medium of unrest that enemies can work through, such as difficulties regarding hours, wages, housing, methods of employment, propaganda distribution, minor grievances, etc.

The Federal government cannot protect a plant that will not protect itself.

There is no time to replace either men or products.

Insurance covers your loss but does not help the Allies win the War.

Americanization insurance will help to win the War.

Restriction of Graphite Imports

The Committee on Mineral Imports and Exports, consisting of C. K. Leith, Pope Yeatman, and J. E. Spurr, representing the Shipping, War Trade, and War Industries Boards, have reported to E. F. Gay, of the Shipping and War Trade Boards, recommendations concerning the restriction of graphite importation from Ceylon and Madagascar, which have been approved by the War Trade Board. In accordance with the recommendations, a three months' embargo has been placed upon importations of graphite, and the importation for the remainder of the year will be limited to 5000 tons. The usual annual importation of Ceylon and Madagascar graphite is about 25,000 tons. The stocks on hand constitute sufficient margin of safety for this program.

The reduction of importation is made on the assumption that the production from Alabama, the chief source of domestic supply, will be commensurately increased. A great improvement in the standardization of domestic graphite as to size and purity must be made before the Alabaman flake graphite can win the confidence of the manufacturers of graphite crucibles. There has been considerable prejudice against using any of the domestic supply, and all makers prefer to use as little as possible, and seldom more than 20% in the formula in conjunction with 80% of Ceylon graphite. Satisfactory crucibles can be made from domestic graphite exclusively. It has been done, and it is entirely a question of standardizing the product. It has been suggested that the Alabama Graphite Association act as selling agents for the producers in the South and that it inspect, sample, and guarantee as to grade and analysis, all the material shipped to the manufacturers.

POTASH, in the form of the carbonate, is being offered to this country from Formosa. The amount available is 200,000 lb. per month, and it can be delivered at New York for about 52c. per pound.

Bill Creating War Finance Corporation

Among the many methods by which industries contributory to the war program may be financed through the Government, is a measure recently passed by Congress in the nature of a charter for a great corporation, having a capital of \$500,000,000 provided through appropriation from national funds. It has received comparatively little attention among those engaged in mineral production. The preamble states the object as follows: "An Act to provide further for the national security and defense, and, for the purpose of assisting in the prosecution of the War, to provide credits for industries and enterprises in the United States necessary or contributory to the prosecution of the War, and to supervise the issuance of securities, and for other purposes."

The sections of interest to the mining world are given below.

SECTION 8. That the corporation shall be empowered and authorized to make advances from time to time upon such terms, not inconsistent herewith, as it may prescribe, for periods not exceeding one year, to any savings bank, banking institution, or trust company in the United States which receives savings deposits, or to any building and loan association in the United States, on the promissory note or notes of the borrowing institution, whenever the Corporation shall deem such advances to be necessary or contributory to the prosecution of the War, or important in the public interest: Provided, That such note or notes shall be secured by the pledge of securities of such character as shall be prescribed by the Board of Directors of the Corporation, the value of which, at the time of such advance (as estimated and determined by the Board of Directors of the Corporation) shall be equal in amount to at least 133% of the amount of such advance. The rate of interest charged on any such advance shall not be less than 1% per annum in excess of the rate of discount for 90-day commercial paper prevailing at the time of such advance at the Federal Reserve Bank of the district in which the borrowing institution is located, but such rate of interest shall be in no case greater than the average rate receivable by the borrowing institution on its loans and investments made during the six months prior to the date of the advance, except that where the average rate so receivable by the borrowing institution is less than such rate of discount for 90-day commercial paper, the rate of interest on such advance shall be equal to such rate of discount. The Corporation shall retain power to require additional security at any time.

SECTION 9. That the Corporation shall be empowered and authorized, in exceptional cases, to make advances directly to any person, firm, corporation or association, conducting an established and going business in the United States, whose operations shall be necessary or contributory to the prosecution of the War (but only for the purpose of conducting such business in the United States and only when, in the opinion of the Board of Directors of the Corporation, such person, firm, corporation or association is unable to obtain funds upon reason-

able terms through banking channels or from the general public) for periods not exceeding five years from the respective dates of such advances, upon such terms, and subject to such rules and regulations as may be prescribed by the Board of Directors of the Corporation. In no case shall the aggregate amount of the advances made under this section exceed at any one time an amount equal to 12½% of the sum of (1) the authorized capital stock of the Corporation plus (2) the aggregate amount of bonds of the Corporation authorized to be outstanding at any one time when the capital stock is fully paid in. Every such advance shall be secured by adequate security of such character as shall be prescribed by the Board of Directors of a value at the time of such advance (as estimated and determined by the board of directors) equal to (except in case of an advance made to a railroad in the possession and control of the President, for the purpose of making additions, betterments, or road extensions to such railroad) at least 1.25% of the amount advanced by the Corporation. The Corporation shall retain power to require additional security at any time. The rate of interest charged on any such advance shall not be less than 1% per annum in excess of the rate of discount for 90-day commercial paper prevailing at the time of such advance at the Federal Reserve Bank of the district in which the borrower is located.

SECTION 10. That in no case shall the aggregate amount of the advances made under this title to any one person, firm, corporation, or association exceed at any one time an amount equal to 10% of the authorized capital stock of the Corporation, but this section shall not apply in the case of an advance made to a railroad in the possession and control of the President, for the purpose of making additions, betterments, or road extensions to such railroad. The Act from which the foregoing excerpts have been made is now law, having been signed by President Wilson on April 5.

NITRATE will be manufactured at Knoxville, Tennessee, from power developed hydro-electrically in that State, and in Georgia and Alabama. A report by a Committee of the Ordnance Department shows that, by inter-connection between the lines of eight power companies in that region of the Appalachians there will be 150,000 hp. immediately available for nitrogen fixation, which will be increased to 450,000 hp. by the end of this year, and to 680,000 hp. by the end of 1919.

ARSENIC, in the form of arsenious oxide, or 'white arsenic,' containing 99% As_2O_3 , by order of the Food Administration is to be sold at not over 9c. per pound delivered to any point in the United States. This applies to less than carload lots. An advance upon this price of ½c. per pound is allowed to local dealers.

THE Hydro-Electric Power Commission of Ontario has installed recently the equipment for producing an additional 50,000 hp. from the plant of the Ontario Power Company.

REVIEW OF MINING

NEW YORK

The Liberty Loan.—Gold Mining.—Appropriation for Mining.

Success is not always gauged by statistics alone. Four million persons subscribed to the first Liberty Loan; two billion dollars was asked; over three billion dollars was raised. The loan was a success. Nearly nine and a half million persons subscribed to the second Liberty Loan; three billion dollars was asked; over four and a half billion dollars was raised. This loan was also a success. The third loan is now being launched, and a large over-subscription is predicted, together with a large increase in the number of subscribers; but if five billion dollars is raised from fifteen million people with only three billion dollars asked, the result will not, in any way, reflect on the success of the previous loans. Since they were floated we have become educated to the idea of thrift, and the reason for the loan, and the justice of the cause for which financial support is asked. An evolution of ideas has taken place in the meantime. People are realizing their obligations to the Government, which is realizing the value of individual moral support, even from the humblest of us. The two first loans realized \$5,808,766,150. To the captious critic who calculates that this represents but a small fraction of the available wealth of the United States the figures will indicate a lack of appreciation of the issues involved calling for caustic comment. The economist will use the statistics in a comparative manner to prove, without doubt, that a steady and satisfactory progress is being made fulfilling all reasonable expectations. Demands for the instant recognition of complex conditions bespeak a lack of appreciation of the fact that slow-moving reforms are invariably the more permanent. For this reason the net result of religious revivals is often negative. The War calls for the daily solution of fresh problems. It has stimulated research in avenues hitherto disregarded. It demands attention to matters previously ignored. Emergencies create men of action; but it would be unfair to assert that such men had wasted their latent abilities before the emergency arose. It is a matter for congratulation that such a great proportion of our potential energy remains in reserve to meet what demands the future has in store for us. If there was no future to consider there might be justification for the policy of clamoring for nothing less than the maximum possible. The Government might, with this idea in view, call for donations to the Treasury rather than subscriptions to a war loan; but it knows well that steady success is best obtained by conserving individual earning power, individual credit, and individual resources as much as possible. The same argument also applies to all other private or national effort. The spectacular achievement too often prejudices sustained effort.

The high cost of production has extended to an industry where there is little hope of any corresponding rise in the market price of the product. Gold mining has been adversely affected to a considerable degree, and the net result is seen in a progressively declining production. During March, the Transvaal reported less gold output (696,000 oz. for the month) than during any previous month since the

outbreak of the War. South Africa produces a large proportion (41%) of the world's output of yellow metal, and statistics show that 27,862,851 tons of ore was milled on the Rand in 1917, against 29,175,468 tons during the previous year. The yield declined in value over six million dollars. In the United States it has been estimated that the increased cost of mining and milling gold ores has risen 18% during the past year; and this, in large measure, accounts for the precarious position in which a great number of small concerns and a few large producers are placed. There has been a steady decline in domestic production of gold since 1915, when the value stood at \$101,035,700. During 1916 it dropped to \$92,390,300, and for 1917 the production was only worth \$84,456,600. This phase of economics was discussed by a committee recently appointed by the New York Section of the American Institute of Mining Engineers to report on the effects of price-fixing and taxation as affecting the mining industry. Attention can be drawn to the unsatisfactory condition of gold mining, but beyond that it is difficult to go. It is impossible to consider the raising of the market-value of the metal, and it is equally impossible to view with any optimism the prospect of reducing the cost of labor or materials required to produce it.

Much interest is being displayed in the suggested appropriation of \$50,000,000 to aid the prospecting for and exploitation of properties in the United States for the purpose of encouraging the output of various metals. The minerals found in the United States but now imported in quantity are manganese, pyrite, platinum, mercury, wolfram, sulphur, tin, and graphite. Graphite comes from Ceylon, pyrite from Spain, platinum from Columbia, manganese from Brazil, etc. The encouragement of local production is praiseworthy, and the discovery of additional deposits of the less valuable minerals mentioned would release many ships now engaged in the import trade, and would tend to stabilize the prices of the products.

PLATTEVILLE, WISCONSIN

Conditions in March.—Ore Prices.—Improvements.

During March the zinc-lead region found many obstacles in the path of regular operations. These were, lower prices for ores, a bad storm of sleet knocking down telephone and power lines, damage to plants, and bad roads. Production fell at mid-month to 50% of normal.

Prices at the beginning of March were \$61 per ton for 60% zinc ore, and \$58 for second grades. Ten days later these fell away to \$60 and \$55, respectively; followed by \$58 and \$53 at mid-month, and \$53 and \$48 at the end. On lower grades, ordinarily sent to refining plants, buyers of 55% ore offered \$45 at the close of the month, \$40 for 50%, \$31.50 for 45%, \$27 for 40%, \$25 for 35%, and \$21.50 for 30% ore. Low-grade producers restricted output, shipments of finished ore were withheld, and deliveries were light. Reserve of all grades in the field at the end of March was carefully computed as in excess of 5000 tons. Operators were despondent over the immediate outlook. Many expressing the belief that the bottom had not been reached, and it was mooted strongly in many quarters that shut-

downs of low-grade producers would become imperative unless a change for the better manifested itself quickly. Lead-ore prices were firm throughout the month, \$87.50 to \$90 per ton being offered. About the 15th there was a recession to \$85. This is a fair price, as lead is a by-product in Wisconsin. Pyrite in reserve at the beginning of March was over 6000 tons, but this was reduced to 1500 tons by April. The price was only 7c. per unit of sulphur. Wisconsin pyrite contains from 30 to 35% sulphur.

Improvements aiding operations in the field included the use of gondola coal-cars with wood bottoms covered with burlap for carrying concentrates, completion of zinc-oxide works at Hillsboro, Illinois, for treating carbonate ore, and better labor conditions brought about by negro help.

VICTORIA, BRITISH COLUMBIA

Summary of Mineral Production in 1917.—Government Aid to Mining.

In submitting to the Legislature Assembly his estimate of expenditure for British Columbia during 1918, the Hon. John Hart, Minister of Finance for the Province, gave an illuminating summary of its mining activity throughout the past year, taking a most optimistic view of the prospects for 1918.

For the year 1917 the approximate value of mineral production was \$37,182,570. That for 1916 having been \$42,290,462 it will be seen that there was a decrease of \$5,107,892. The total mineral production of the Province to the end of 1917 reaches \$595,743,285. It must not be taken that there was any decline in the industry itself during 1917, the explanation being found in the cumulative effect of several adverse influences, such as: industrial troubles, reduced metal prices in the last quarter of the year, less demand for lead and zinc for munition purposes, and economic conditions that severely handicapped the mining for gold.

The output of metalliferous mines during 1917 is estimated as \$27,663,786, against \$32,063,514 in 1916. The most serious decreases were in production of gold, copper, and zinc. Gold, which fell off \$2,173,834, was set back mainly because of the decline in the Rossland field, which usually provides 55% of the output; also because of the increased cost of labor and supplies. Copper, which shows a decrease of \$1,091,457, and zinc, \$1,493,872, were directly affected by industrial troubles. The extraction of 61,416,617 lb. of copper and 33,776,335 lb. of zinc, both greater than shown in any previous year except 1916, must be considered satisfactory under the circumstances. Silver and lead increased \$359,435, which is especially gratifying. Production of coke was 159,554 long tons, an increase of 40.5%. About 129,155 tons was produced by the Crow's Nest Pass Coal Co., being a drop of 110,960 tons. Having met with a series of misfortunes early in the year, a condition aggravated by shortage of labor, this company's collieries were unable to maintain their output and, as a direct consequence, the large smelters of the interior were unable to obtain their usual supplies of fuel. This is one of the chief explanations of the failure, although by a small margin, why the value of the Province's metalliferous mines output in 1917 was less than that of 1916. It is estimated that the net coal production for 1917 was 76,324 long tons greater than in 1916, again nearly approaching the pre-war rate. The Vancouver Island collieries made an output of 1,698,235 tons, a record, a gain of 205,474 tons. Production of British Columbian collieries in 1917 was valued at \$8,518,784, a decrease of \$381,891.

The total quantity of ore mined in British Columbia in 1917 approximates 2,597,725 tons, against 3,200,000 tons in 1916, and 2,700,000 tons in 1915.

The effect of the application during 1917 of the Mineral Survey and Development Act was as follows: In accordance

with its provisions the Province has been divided into six mineral survey districts, with qualified engineers in charge of each. On their recommendations the expenditure of \$127,628 has been authorized for construction of roads and trails to mines. Prospectors, operators, and generally all engaged in mining have welcomed this measure as one to stimulate production. Under this Act, diamond-drilling is to establish as nearly as possible the available quantity of iron ore in British Columbia; also the best means of establishing a modern plant for its reduction to metal.

CRIPPLE CREEK, COLORADO

General News of the District.

The United Gold Mines Co. has made an important discovery in its Wild Horse mine on Bull hill and is again producing steadily. By a raise, driven for ventilation between the Gleason and Wild Horse workings, there has been opened 3 ft. of smelting-grade ore, between the 400 and 300-ft. levels of the Wild Horse shaft. A 10-in. mud-seam carries from 5 to 10 oz. gold per ton by grab sampling. A shipment of over 2-oz. ore was made last week. Carl Evans is superintendent.

Two cars of high-grade ore, under armed guard, was sent from the Cresson mine on April 12. This ore was mined from a new shoot, reported to be 30 ft. wide, on the 1000-ft. level.

Diamond-drills will soon be used for prospecting in Cresson ground from the Roosevelt drainage-tunnel, at a depth of about 1800 ft. from the surface. A station is now being cut for this purpose in the Cresson lateral at a point 600 ft. north of the tunnel in the Old Ironsides claim of the United Gold Mines Company.

The Portland company has declared the regular quarterly dividend of 3c. per share payable April 20. The amount, \$90,000, will bring the total sum paid to \$11,137,080.

The final clean-up at the Colorado Springs mill of the Portland company commenced on April 8. Machinery is to be shipped to the company's independence mill at Victor. Most of the millmen are to be given employment at this plant.

The El Paso Extension, operating the Index mine on Gold hill under bond and lease, is shipping steadily, 12 cars having been loaded since the first of April. Settlements have ranged from 1 oz. to nearly 3 oz. The car of the latter grade was mined at the 300-ft. level by sub-lessee. The company ore is mined at a depth of 1115 ft., and is worth close to \$30 per ton. Low-grade ore mined by sub-lessees in other levels realizes \$18 to \$20 per ton.

Harry MacDonald, cashier of the Cripple Creek State Bank, has been appointed manager for the Patterson-Bradley Leasing Co., operating the Specimen and Sacramento mines of Stratton's Cripple Creek Mining & Development Co. Deep development is planned for these two Bull Hill properties.

The Du Pont de Nemours Powder Co. is about to construct a suitable magazine in this district, to be on the north-east slope of Tenderfoot hill. Surveyors have staked the grade for a track to the site, extending from the High Line road at Hoosier Pass, and grading is under way.

The monthly dividend of the Golden Cycle company of 3c. per share, \$45,000, was paid on the 10th.

The Vindicator Consolidated company again decided to pass the quarterly dividend. The company has paid its taxes and current expenses, and has approximately \$100,000 cash on hand. George A. Stahl has been elected general manager to succeed Irving T. Snyder, who resigned. The former has been secretary for many years.

The Ajax Gold Mining Co. has decided to dissolve the corporation. The properties formerly owned by the company on Battle mountain are being operated by the Carolina company.

THE MINING SUMMARY

ALASKA

Fairbanks.—First coal shipments from the Nenana field reached Nenana early in February. This comes from Lignite creek, and more is to be hauled to the present end of the railway. The more accessible part of the Nenana field has been divided into leasing blocks, none to exceed 2560 acres. There are at least 12 coal beds of workable thickness, six being over 20 ft. The coal is a lignite of fair grade, suitable for interior Alaska.

Steina.—Ion E. Barrett and Mr. Dwyer, agents for the Copper River & North Western railroad, report that Ole Berg has developed over a million dollars worth of gold ore in his mine near here.

ARIZONA

Bisbee.—This district is producing 1000 tons of manganese ore per month. The Higgins Leasing Co. is shipping 150 tons weekly, mining this from near the surface. Calumet & Arizona and Copper Queen also produce the ore.

Douglas.—Calumet & Arizona smelter produced during the first three months of 1918 approximately 20,000,000 lb. of copper, an increase of nearly 4,000,000 lb. over the yield for the same period of last year, which was 16,708,133 lb. Total production of the smelter for 1917 was 93,037,123 lb., of which 33,683,983 lb. was from custom ores, making the Calumet & Arizona output for the year 59,353,140 lb. In 1916, the production of this company was 70,041,139 pounds.

Globe.—Ore carrying several hundred ounces of silver and 30% copper has been extracted from the Manibesta Copper & Silver Co.'s mine in El Capitan district. High-grade copper ore carrying silver is also being mined at Copper Vault property in the Cole-Goodwin district. J. J. Sherwin is in charge.

Billy Hogerty and Harry Malloy have, in cross-cutting 300 ft. on their claims in Mineral Creek district, cut a vein over 40 ft. wide, of which 5 ft. carries 28% copper, \$6.40 gold, and 10 oz. silver per ton. They estimate an immense tonnage of lower-grade ore, averaging better than \$30 per ton in the three metals.

Hackberry.—On 700-ft. level of old Hackberry mine there is 5 ft. of 80-oz. ore. Reserves in mine are estimated at 200,000 tons, assaying 20 oz. silver per ton, with some gold, lead, and zinc. A 200-ton concentrating plant is to be erected.

Jerome.—Sinking has been resumed at the Verde Combination from 700 to 1000 ft. In March 730 ft. of development work was done.

Softer ground is being encountered in the shaft of the Gadsden, which is down 968 ft. The pump in use on the 800-ft. level will probably have to be returned to the United Verde Extension, which will delay sinking if the new pump does not arrive.

The United Verde Extension has encountered a heavy flow of water.

Outman.—Tom Reed company has opened Bald Eagle vein for 500 ft. on 525-ft. level. Average width is 7 ft. Mill is producing gold worth \$150,000 per month.

The Telluride is drilling, hoping to cut main vein of Tom Reed.

Parker.—The Red Cloud Consolidated Mining Co. has just purchased machinery including two sets of rolls, a crusher, and two concentrators.

Prescott.—The General Mines Co., developing the Amulet mine in the Walker district, has its new shaft down 200 ft., and has cut high-grade silver-lead ore in the north drift.

A new 34-hp. gasoline engine is being erected at the Arizona-Portland in Copper basin.

Fitzmaurice and Birch are erecting a new water-propelled quartz mill on their gold mine on lower Lynx creek.

Tucson.—The American Mining Congress Arizona Chapter met here on April 8 and 9. About 30 representatives of the mining districts attended. The bi-monthly meetings, started in 1917, are mainly to aid the Government in every way. It was resolved to do everything asked by the authorities to help put down disloyalty, not to employ members of the I. W. W., that the mining industry should not be subject to any sub-department but by a department of mines headed by a member of the Administration and that the U. S. Bureau of Mines should not be transferred to the War Department.

Wilcox.—The Mascot Copper Co.'s mine here, under 10-year lease to the A. S. & R. Co., was returned to the owners on April 1. No reasons were given for this action. About 35,000 tons of ore, valued at \$500,000, has been extracted.

CALIFORNIA

Angels.—The Angels Camp Deep Mining Co. has resumed operations, in charge of J. C. Benson, president. The main shaft is to be sunk, and electric power used in place of steam. M. Fugina is superintendent.

Red Bluff.—Ten 850-lb. stamps and two Wilfley tables have been started dressing disseminated chrome ore at the

MAP SHOWING CHROME DISTRICT OF TEHAMA COUNTY, CAL.

Kleinsorge property, 7 miles from Lowrey, and 40 miles south-east of Red Bluff. Water-power, under a head of 520 ft., has been developed. This property is in rough country, necessitating use of three aerial trams. The Milton

section produces shipping ore in considerable quantities, as do other scattered parts. A feature of the area is large quantities of disseminated chrome in serpentine, which needs concentrating. Later on we hope to publish details of results obtained. North of the Kleinsorge are several other chrome producers. H. D. Jerrett is in charge.

Caliente.—Toll Gate Mining Co. has been permitted by the State Corporation Commission to issue 24,995 shares to L. D. Collings in consideration for the assignment to the company of all his right, title, and interest in a contract to purchase seven mining claims in Toll Gate canyon, 20 miles east of Caliente, Kern county. Collings is also to pay the company \$6000, which is to be used for the installation of mining and milling equipment.

French Gulch.—Forty men are working at the Sybil mine and ten stamps are crushing ore. Good ore was cut recently in new ground opened from the shaft. The mine is operated by William Blagrove and William Franck.

Los Angeles.—According to the Chamber of Mines and Oil the first potash prospecting permit has been issued, covering 2560 acres of marsh land in Inyo county. Under the new law permitting the exploration of potash lands, a corporation or individual may secure the exclusive right to prospect on 2560 acres of supposed potash land for a period of two years. Discovery of potash in commercial quantities will entitle the permittee to patent for 640 acres, the balance of the 2560 acres being retained by the Government to operate or lease at its discretion. In the past there has been no incentive to develop potash deposits, to which title could not be acquired.

St. Louis.—The Loftus Gold Mining Co. of Los Angeles has started hydraulicking near Howland Flat in Sierra county. It is reported that over \$200,000 has been spent in ditches and an impounding dam, also that 10,000 yards of gravel will be sluiced daily.

Smartsville.—A. C. Paul has taken bond and lease on Green Lead copper mine from Thomas Mooney of Marysville, and started work. The mine produced 30 years ago, ore being shipped to Swansea, Wales. Mr. Paul is operating the McGonigal property profitably.

COLORADO

Central City.—The Perigo mines and mills at Perigo have been taken over by S. J. Gish and D. W. R. Finney, who are to re-open the workings and re-model the plants.

Cripple Creek.—The Cresson profit for March is expected to be over \$100,000. Drift No. 915 has opened ore averaging \$50 per ton.

Ouray.—The Camp Bird adit was driven 515 ft. during March. The main vein is expected to be cut by the middle of May, when driving both ways will be commenced and continued for a distance of 1500 ft., and raises of 500 ft. started to connect with shaft workings above.

The Mountain Top M. & N. Co. is operating at full capacity, both milling and shipping crude ore. Concentrate is of high value. G. Barnhart, the manager, hopes to sink on the vein several hundred feet into the andesite formation to prove the theory that richer ore is below the present workings, which are in rhyolite.

Ouray Mining, Smelting, Milling & Refining Co., Thomas Crawford in charge, is pushing completion of two mills for concentration of low-grade ores. The one at Iron-ton will be ready by May 1, and the one connected with the smelter below this city was expected to be ready by April 15. The smelter would be in operation now if there were sufficient copper sulphide ores available. Mr. Crawford has leased the Treasury Mining & Tunnel Co.'s property at Red Mountain and expects to commence operating these after June 1, 1918.

Among the new ventures will be the Hudson Leasing Co., which will unwater the Hudson mine and commence mining copper ores. Otto Arps is president of this company.

Rico.—The Pro Patria claim has been opened by the Rico Mining, Light & Power Co., and a large force of men is at work.

Muddy roads are interfering with ore hauling.

The Rico Argentine and the Rico-Marmatite lease are shipping heavily.

The Cadiz mine has a number of cars ready for shipment.

IDAHO

Arco.—Wilbert Mining Co. is sinking new shaft to depth of 800 ft., now down 250 ft. Monthly progress is 150 ft. A little ore is being mined at 300 ft., and the mill works intermittently. In a block of ground at 800 ft. depth there is estimated to be 5000 tons of ore blocked out, some carrying 50% lead and 15 oz. silver per ton. Mine is in the Dome district, 35 miles from rail at Arco.

Elk City.—In the Ten-Mile district of Idaho county there are 8 mills working or in course of erection. These are at the New York, Mackey, Lone Yellow Pine, Gilt Edge at Newsome, Davis, Warder, and Black Pine and Mineral Zone at Elk City. The plants use stamps and Gibson mills. Miners and millmen are in demand.

Porthill.—The Idaho-Continental company, in charge of A. Klockman, resumed mining and milling last week, after a shut-down since last fall due to lack of water. The plant is dressing 200 tons of lead-silver ore daily. About 100 men are employed.

Wallace.—Success Mining Co. on Nine-Mile creek suspended operations last week, on account of a dispute with the Grasel Chemical Co. over payments for zinc ore delivered. Directors are to go to Washington, D. C., to complain to the authorities.

MISSOURI

Joplin.—Production of the region last week was 6140 tons blende, 210 tons calamine, and 1242 tons lead, averaging \$41, \$35, and \$85 per ton, respectively. Total value was \$365,419, making \$7,199,321 for 15 weeks. Oklahoma contributed \$226,862 to last week's total.

MONTANA

Butte.—Anaconda company, while cross-cutting from its Belmont mine to the 2500-ft. level of the Davis-Daly for ventilation purposes, last week cut 5 ft. of 8% copper ore.

Davis-Daly's Colorado mine is shipping 250 tons daily of ore assaying 11 to 14% copper and 12 oz. silver, and 4% copper and 6 oz. silver per ton. About half is of the first grade. Sinking at the Hibernia is hindered by water.

Kendall.—Barnes-King Development Co. in March extracted gold worth \$55,036 from 5622 tons of ore. The grade varied from \$5.49 to \$11.20 per ton. The February yield was \$72,455.

NEVADA

Beowawe.—Salt Lake City people have acquired the Silver King mine and appointed J. B. Lamb as superintendent. A 35-hp. hoist has been sent to the mine and preparations made for early shipments. Ore carries silver and lead, with best grade assaying \$130 per ton.

Brunner.—Brunner Con. Mines Co. has established a camp and post-office, and is operating with 32 men. Water will be brought to camp from O'Neil springs, 10 miles distant. A 150-ton mill will be erected in 25-ton units. Development has been in progress eight years. Main offices are at Kansas City, Missouri.

Bullfrog.—This district is active. The Mayflower is shipping \$22 gold ore to Kennett, Cal., smelter, and has 10

stamps dropping. The remaining five stamps will be working shortly, and capacity of mill probably increased. Development is proceeding from 200, 300, and 400-ft. levels of Mayflower shaft, and from surface workings on Starlight claim. Shipping ore is mined on Mayflower vein at points 1400 ft. apart. W. J. Tobin is manager.

Fallon.—The Nevada Potash Syndicate has started drilling in Dixie valley to test brine beneath rock-salt deposits. The manager, E. N. Richardson, states that silt overlying salt-beds assays 2 to 3% potash.

Goldfield.—Re-treated tailing from the Goldfield Consolidated mill has been leased to M. G. Bradshaw and others, who will sweep dumps for the rich material that collects on the surface.

Goodsprings.—In the Annex mine there is now 7 ft. of rich lead-silver ore, an important development.

At the Hoosier, work is under way on the mill-site. A 4½-mile water-pipe line is being laid.

The Yellow Pine company has purchased Liberty Bonds amounting to \$25,000, making \$100,000 to date.

Hazen.—According to F. M. Manson of the Western Ore Purchasing Co., development of chrome and manganese deposits in this State will be considerable within a few months. His company has arranged to handle small or large lots of these ores, paying for them at the smelter as is done with other ores.

Nelson.—Considerable interest is being aroused here (Clark county) by exploitation of Copper Canyon by the M. & D. Mining Co. of Salt Lake City. An Okell drill, using a specially treated steel cutting-tool, and taking out a five-inch core, has been set up in Copper Canyon, one mile from Nelson. Drilling is under way, and the management is prepared to go to 900 ft., and expects to reach primary chalcocite at 800 ft. Already \$122 gold-silver-copper ore has been taken out. An average taken over 125 ft. of the exposed orebody on the surface showed 3% copper. The president of the M. & D. company believes this orebody to be the outcrop of an extensive zone lying east and west.

A combination air pipe-line and water pipe-line is being laid down from the Techatticup mine to the Crown Queen mine. The latter is expected to start soon.

Rand company is now working both mine and mill, having obtained enough water.

Tonopah.—Some March outputs were as follows:

Mine	Tons	Silver, oz.	Gold, oz.	Profit
Belmont	9,040	114,499	1,172	\$63,200
Tonopah Mining	15,102	113,103	1,143	41,200

There is nothing of importance from the Divide district this week.

The Monarch Pittsburg Mining Company, through its superintendent, B. H. Smith, reports that during 1917 there was 1649 ft. of development done at a cost of \$14.27 per foot. Certain work in progress resulted in ore being discovered at about the 900-ft. level. Drifts on 850-ft. level exposed a persistent body of \$3 to \$11 ore, but later on it became bunched and erratic. The West End company having opened its Ohio vein on 500-ft. level, it was decided to prospect that part of the Monarch Pittsburg above the 850-ft. level in search of this vein. A raise is up 160 ft. in rhyolite toward the overlying trachyte. Geological conditions are considered better than before for finding large bodies of ore. Receipts during 1917 were \$35,395, of which \$28,595 was from assessments and \$1100 from ore sold. Cash balance of \$4304 at beginning of year was wiped out.

NEW MEXICO

Lordsburg.—The new 400-ton gravity and flotation concentrating mill at the Eighty-Five mine is in commission.

It is driven by a Diesel electric-power plant. Ore carries copper, gold, and silver. Deepest shaft is 750 ft., with more than four miles of underground workings. A. J. Inder-rider is manager.

North of Lordsburg is the new mining camp of Itedrock, where are big deposits of fluorspar being developed. The mineral will be hauled to Lordsburg by auto-truck, and shipped to San Francisco. The ore contains silica, 0.4%, lime, 50.17%, and fluorine, 48%. J. A. Cauthen is manager.

Silver City.—The deposit of manganese ore on Boston hill, west of Silver City, is extensive, as shown during the last year's development by Robert I. Kirchman and Perry Crawford, who for 12 months have shipped to Pueblo, Colorado, 1500 tons per month. A more uniform price for manganese ore and a better supply of cars would enable them to ship from 10,000 to 20,000 tons per month.

OREGON

Sumpter.—Powder River Gold Dredging Co. reports as follows, through C. W. Gardner, manager for the Hammon Engineering Co., which is in charge of the property:

During year ended September 30, 1917, gold extracted

MAP SHOWING BAKER COUNTY DISTRICT, OREGON

was sold for \$516,234, of which \$314,990 was profit. Current assets were \$183,808, and liabilities \$20,690. No. 1 dredge will continue to dig a good quantity in 1918, but with decreased gold content; while it was expected that No. 2 would have finished its ground by December last. Ground near Breckenridge, Colorado, was acquired on terms, and a boat was to be finished late in December 1917. Estimates place gravel in this new property at 15,000,000 cu. yd. Some details of operations last year are as under:

	No. 1 dredge	No. 2 dredge
Ground dredged, cubic yards	1,617,846	1,993,067
Average daily operating time, hours	19.97	20.71
Average daily yardage	4,829	5,862
Gold recovered, cents per yard	17.04	12.07
Cost, cents per yard	6.13	5.12
Net profit	\$176,566	\$138,424

Compared with previous year the profit was 18 and 37.3% less, respectively.

OKLAHOMA

Donthat.—Skelton Lead & Zinc Co. is the second largest producer in the Oklahoma field, and has 7 mills dressing 1000 tons of ore per shift.

Picher.—Production of Oklahoma districts last week

amounted to 3661 tons blende and 860 tons lead, valued at \$226,862.

Tar River.—A year ago this place was of no importance; today it has a population of 6000 people, and is the centre of much mining activity. Originally it was called Cardin. There are about 100 mines and mills in the district.

TEXAS

Dalberg.—The West Texas Mica Co. of Houston is developing, mining sheet, and producing large quantities of ground mica from an extensive deposit 9 miles from this place. This ground mica is made into what is known as 'golden bronze,' used for decorative purposes. The region in which this ore occurs is typically desert. This company, with a capital of \$2,500,000, started operations in 1910. An interesting feature is the manufacture of chicken grit.

Quannah.—Considerable quantities of copper ore are being shipped by companies operating in Hardeman, Archer, and other counties of this region. The Texas Development & Mining Co. is developing a claim in Haskell county, and is preparing to erect a concentrating plant. It is stated that this mill will be at Rule. T. Stanford Gibbs of Chillicothe, who holds a lease on 18,000 acres in Hardeman county, including Medicine Mound where copper mines were worked 25 years ago, is extracting copper nuggets in sufficient quantity to make regular shipments. Since December 20, 1917, he has shipped three cars of this material to the smelter. He proposes to build a plant.

UTAH

The Utah Oil Men's Association was formed at Salt Lake City last week to look after the oil industry of this State. E. D. Woodruff was appointed president, and G. F. Barton secretary.

Alta.—Wasatch Mines Co. recently received settlement for a car of ore containing 110 oz. silver, \$2.13 gold per ton, 25.5% lead, and 1.5% copper. Value was \$112 per ton. The drainage-adit is in 1950 ft., cutting a few seams of galena.

Transportation troubles up the canyon include deep dust on the main road and 4 to 5 ft. of snow along the sides. The Little Cottonwood Transportation Co. expects to have its line complete to the mines this summer. Haulage to smelters from Alta will be from \$2.50 to \$2.75 per ton.

Lark.—Ohio Copper Co.'s new flotation plant is to be ready by May 1. Mill consists of three units of 600 tons each. It will dress slime from the old mill, which is handling over 2000 tons daily, extracting about 50%.

Park City.—Ontario Silver Mining Co. has opened large shoots on 1600 and 1700-ft. levels. During 1917, company sold ore worth \$315,159 and silver \$123,753. Assets at beginning of year were \$311,620, and at end \$376,299. Latter includes stocks and bonds valued at \$316,023.

Provo.—Dragon Consolidated paid 1c. per share on April 25. This amounts to \$18,750, and makes \$37,500 for 1918 and \$112,500 to date.

Tintic.—Iron Blossom pays 2½c. per share on April 25, equal to \$25,000. Total to date is \$3,125,000.

Chief Consolidated paid 10c. per share on May 6, equal to \$88,420. This makes a total of \$1,013,811.

CANADA

British Columbia

Ainsworth.—The Florence Silver Mining Co. is again working its mill one shift daily, dressing 90 tons of ore. In March, products sold realized \$21,219. On April 25 two shifts were started, and 30 additional men employed, making 75 in all. New quarters are available for the men.

Princess Royal Island.—Surf Inlet mine of Tonopah Belmont company made a profit of \$33,000 during February.

Silverton.—Standard Silver-Lead Mining Co. made a profit of \$377,494 in 1917, against \$388,364 in 1916. Receipts were \$867,551. Dividends amounted to \$300,000. Balance brought forward to 1917 was \$202,801, and to 1918, \$336,943. Lead ore was sold for \$364,046, and zinc ore for \$462,792.

Ontario

Kirkland Lake.—The Burnside mine is now being opened, No. 2 shaft being sunk to 155 ft. depth. From this point a cross-cut will be driven to the Tough-Oakes mine.

The Dome Lake Mining & Milling Company in 1917 treated 16,388 tons of \$4.16 ore. There was extracted \$2.75 per ton. Costs totaled \$8.14, leaving a loss of \$5.39 per ton. Ore-reserves are estimated as worth \$57,492. Diamond-drilling indicates better ore, and the mill can now treat 150 tons per day.

Porcupine.—Good ore has been opened on 500-ft. level of the Dome Lake mine, better than in other parts of the property.

The McIntyre Porcupine property continues to open well. Results of the two half-years of 1917 compare as under:

Period	Tons	Value	Cost	Profit
First	86,086	\$10.46	\$4.94	\$4.87
Second	89,807	10.48	5.04	4.58

Newray company's shares held by Crown Reserve and Dominion Reduction companies are said to have been sold.

Dome Lake mill when finished is to treat ore from West Dome Consolidated. For a start, 1000 tons is to be tested.

Davidson Mining Co. reports for 1917 that development totaled 3096 ft., also 2115 ft. of diamond-drilling, costing \$83,000. Reserves are given as 100,000 tons of \$10 ore down to 300 ft., while drilling revealed 35 ft. of ore at depth of 500 ft. Sixty-ton mill is ready for treatment.

KOREA

Ulsan.—Oriental Consolidated Mining Co.'s clean-up for February was valued at \$124,255. In January, 25,377 tons of ore yielded \$126,006, of which \$32,196 was net profit.

PERU

La Fundicion.—Cerro de Pasco continues to operate at full capacity. Its second hydro-electric plant was recently completed at Pachachaca, on line of Ferrocarril Central del Peru. It consists of a 3500-kw. Allis-Chalmers 2300-volt generator, driven at 300 r.p.m. by a tangential-type water-wheel under head of 790 ft. Water comes from lakes 14,000 ft. above sea-level, passing through a regulating reservoir, 9100 ft. of 48-in. wood-stave pipe, and 2640 ft. of steel pipe tapering from 48 to 32 in. Nozzles are 6 in. diameter. Discharge water is to be used again at the other power-plant at Oroya, 20 kilometres distant. Total capacity of installations is now 20,000 hp., transmitted over 189 miles of cables. Cerro de Pasco Mining Co. is completing plans for the addition of a new 400-ton unit to its mill. This will consist of primary rock-breakers and picking-belts for segregation of high-grade ore and fine to be sent to the smelter. The rejected coarse material from the picking-belts will be sent to a plant consisting of secondary crushers, rolls, and ball-mills. The crushed and coarser fine sand will be concentrated on tables, and the finer materials treated in a flotation plant.

Lima.—National Mining Congress sat here during third week of January. It was decided to make known the mineral resources of the Republic, to stimulate investment of foreign capital. More railroad construction was urged to develop the mineral areas. Cerro de Pasco, Backus y Johnson, and International Petroleum companies employ over 13,000 people in Peru, and contribute a total of Lp. 480,000 (1 libra = \$4.87) per annum to the customs department.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Charles Janin has gone to Washington.

George C. Stone has gone to Australia.

L. S. Austin is at San Pedro, California.

Samuel H. Dolbear has returned to San Francisco.

F. L. Sizer is at Alleghany, Sierra county, California.

Benjamin Wilson, of Bisbee, Arizona, has gone to Peru.

Walter M. Stephen is at the Mamie mine, Hadley, Alaska.

F. W. Bradley was at the Atolia tungsten mines last week.

E. Gybbon Spilsbury has returned from Cuba to New York.

R. J. Glendinning, of Salt Lake City, was in San Francisco during the week.

R. S. Bayerstock is examining strontium deposits in the Barstow district of California.

S. L. Pearce of Los Angeles, is going to Alamos, Sonora, as manager of the Promontorio mine.

Alfred R. Whitman has removed his office to 43 Exchange Place, New York, from Cobalt, Ontario.

Douglas A. Mutch has been appointed manager of the Dome Lake mine at Porcupine, Ontario.

C. H. James has been appointed consulting engineer for the Mazatzal Mining Co., of Payson, Arizona.

S. L. Pearce, of Los Angeles, California, is going to Alamos, Sonora, as manager of the Promontorio mine.

D. J. Coffey, of Porcupine, has been appointed general manager of the Lake Shore mine at Kirkland Lake, Ontario.

E. M. Hamilton, of Hamilton, Beauchamp & Woodworth, has gone to Pachuca, Mexico, where he will remain for several months.

Leroy A. Palmer has resigned as mineral examiner, U. S. General Land Office, to take a position as field engineer with the Sufferin Company.

Edward Scallan, lately in Minnesota, has accepted the position of superintendent of the United Verde Extension mine at Jerome, Arizona.

W. J. Richards, head of iron mining interests at Crystal Falls, Michigan, has returned from the South, where he has been spending the winter.

Charles B. Croner, of Pasadena, California, recently examined a number of properties near Grants Pass, Oregon; also in Mariposa county, California.

Herman Garlicks, of Brooklyn, N. Y., has gone to British Columbia and the Pacific Coast to investigate sundry metallurgical problems in the North-West.

Charles Briggs, president of the Calumet & Arizona Mining Co., is expected at Calumet, Michigan, on May 15 from California, where he has been spending a few months.

H. A. Morrison has been appointed superintendent of the lead-silver mine of the Louisiana Consolidated Mining Co., at Tybo, Nevada, in place of A. J. Canavan, who has resigned.

John A. Traylor has resigned his position as Western manager for the Traylor Engineering & Manufacturing Co., but is retaining the general Western agency of the Cement Gun Co. He will devote most of his time to his mining interests, with headquarters at the Newhouse Bldg., Salt Lake City.

William Wraith, general manager for the International Smelting Co., was elected chairman of the Utah section of the A. I. M. E. last week. Cecil Fitch was elected vice-chairman, and F. G. Moses, secretary. These, with E. R. Zalinski and Ernest Gayford complete the executive committee.

H. Kenyon Burch, formerly consulting engineer to the Inspiration and Miami copper companies, has been appointed

consulting engineer, in the concentrating department, to the Phelps-Dodge Corporation, and is now in charge of the design and construction of the 3000-ton concentrator of the Copper Queen Consolidated at Bisbee, Arizona.

Obituary

Harold W. Webster, Major in the Royal Engineers and son of Mr. W. W. Webster, a director of Minerals Separation Ltd., was killed on the Somme battlefield. He was a young man of much promise and had many friends in the profession.

David Keith died at Salt Lake City on April 16 at the age of 71. He was born at Mabou, on Cape Breton island, Nova Scotia, and early obtained an insight into mining by working in the small mines near his home. Of an energetic and adventurous character, he was readily attracted by the stories of gold discovery in California; as soon as he was old enough he shipped before the mast from a port in Maine to the Isthmus of Panama, eventually reaching California, where he heard the story of the Comstock and tramped across country from Sacramento to Gold Hill, Nevada. He began to work as a miner, becoming foreman at the Caledonia and Overman mines, and later manager of the Mexican. In 1882 he went to Park City, Utah, as foreman of the Ontario mine, then controlled by George Hearst and associates. He won a reputation for ability and in 1885 was appointed superintendent for the Anchor, now the Judge, mining company. He became associated with Thomas Kearns, John Judge, E. P. Ferry, and A. B. Emery in operating the Mayflower claims at Park City. This property became the celebrated Silver King mine, which made Mr. Keith a millionaire. At the time of his death he was president of the Silver King Coalition Mines Co. and he had many interests besides, in mines, banks, and railways.

SAN FRANCISCO SECTION A. I. M. E.

The next meeting of the local section of the American Institute of Mining Engineers will be held on Tuesday, May 7, at the Engineers Club, 57 Post street. The dinner (\$1) will be at 6 p.m. and the meeting at 7. Professor C. F. Tolman will give a paper on 'The Ore Deposits of California.'

Two mining engineers are desired to fill vacancies in the Bureau of Mines. These will be Civil Service appointments, made on a competitive basis, but no examinations will be held. Instead of that proofs of rating in the educational institutions from which applicants graduated must be submitted, together with an original essay on some mining problem. The salaries range from \$1200 to \$1500 per year. Applications must be filed with the Civil Service Commission not later than May 14.

The National Electric Light Association, at a meeting of the convention committee, Walter Neumuller, chairman, voted to recommend to the Association that the annual meeting, devoted entirely to war problems, be held at Atlantic City, June 13 and 14, with the Hotel Traymore as headquarters. President Lieb has decided accordingly. The essential requirement is the limitation of the work of the meeting to the consideration of pressing and vital war problems as related to the industry. The secretary is T. C. Martin, 29 West 39th street, New York.

The American Electrochemical Society holds its spring meeting and Southern trip during the period April 28 to May 5. The party leaves Washington on the first day, visiting chemical works at Kingsport and zinc mills at Knoxville, North Carolina; chemical works at Chattanooga, Tennessee; construction of nitrate plant at Muscle Shoals, steelworks at Birmingham, and electric furnaces at Anniston, Alabama.

THE METAL MARKET

METAL PRICES

San Francisco, April 23

Aluminum dust, large and small lots, cents per lb.	65-70
Antimony (wholesale) cents per pound.....	13 3/4
Copper, electrolytic, cents per pound, in carload lots.....	23 1/2
Copper, electrolytic, cents per pound, in small quantities.....	24 1/2
Lead, pig, cents per pound.....	7 1/4-8 1/4
Manganese, pure and with 10% iridium, per ounce.....	\$108-\$110
Quicksilver, per flask of 75 lb.....	\$115
Spelter, cents per pound.....	10
Zinc dust, cents per pound.....	17 1/2

ORE PRICES

Sao Francisco, April 23

Antimony, 45% metal, per unit.....	\$1.10
Chrome, 38% and over, f.o.b. Cal., per unit.....	\$1.25-1.50
Magnesian, crude, per ton.....	\$7.00-8.00
Manganese, 40 to 50%, Hazen, Nevada, cents per unit.....	92-110
Manganese, 48%, New York, cents per unit.....	\$1.20
Tungsten, 60% WO ₃ , per unit.....	\$20-24
Molybdenite, per lb., 85% MoS ₂	\$1.80
Pyritic, domestic, New York, per unit of sulphur, cents.....	28

Chrome production and distribution was recently discussed in a contemporary by Samuel H. Dolbear of San Francisco. He said that one of the problems confronting America was that of increasing domestic supplies of chrome. Last year's output fell off 6000 tons. Deposits near rail were exhausted. Remote deposits can be made available with Government roads. Low-grade ore must be concentrated. Irresponsible brokers have been a burden on the industry. Sampling and settlement of shipments should be standardized. Suggestions as to the remedy are as follows: Place all chrome operations under Government control through license and inspection; provide, without charge, engineering advice to chrome miners; provide financial assistance to chrome concentrating enterprises, and require that construction and operation be supervised by engineers approved by the War Industries Board; prohibit brokerage and speculative transactions in chrome ore and license sale and purchase; and furnish cars promptly, with preferential movement when loaded.

EASTERN METAL MARKET

(By wire from New York)

April 23.—Copper is unchanged. Lead is quiet and easy. Spelter is inactive but steady.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.67c. for small lots, effective until June 1, 1918. Quotations in cents per pound are as under:

Utah.....	16,380,000

SILVER

Below are given official or "ticker" quotations, in cents per ounce of silver 999 fine. The actual figure at which the metal is bought and sold is a matter of negotiation, and is not available, but the prices given indicate such approximately. Premiums are paid up to 3c. per oz. See "M. and S. P." of March 23, 1918, for full details.

The War Industries Board on April 6 reached an agreement with lead producers whereby they will furnish all Government requirements for lead products—6,000,000 lb. minimum and 12,000,000 lb. maximum per month at fixed prices averaging 7c. per pound. The minimum requirement of 12,000,000 lb. per month for the Government is 20% of the entire lead output of the country. No priority orders for delivery therefore will be necessary, the Board announced, unless transportation conditions should affect delivery of the Government orders. This remains in effect for four months.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Tin amounting to 15,942 bars, valued at \$1,500,000, arrived at San Francisco from the Orient on April 22.

Eastern Metal Market

New York, April 17.

The markets are inactive and nearly featureless. The metals that lately have been weak now have declined slightly.

Copper is unchanged and devoid of developments.

Tin is less active and at a standstill, pending important developments at Washington.

Lead is very quiet, and a little lower.

Zinc is dull, and has declined further.

Antimony is unchanged.

In the steel industry plate mills have shown remarkable outputs, more than 110,000 tons having been the production in one week of April. Charles M. Schwab, chairman of the board of the Bethlehem Steel Corporation, has been made director-general of the Emergency Fleet Corporation; this will probably mean a further speeding of effort. Definite moves will be made this week on the project for the greatest American gun plant, which the Government and the U. S. Steel Corporation will build in co-operation, the latter erecting the steel works. It will probably be in the Pittsburgh district, and will include a great projectile plant. The largest machine-shop in the country will be provided.

COPPER

The market is without important developments, and price changes are impossible under present conditions and Government control. A trade journalist of high authority states: "In the counting-rooms the continued tardiness of the Government in making settlements creates financial embarrassments. The Government is said to owe the copper producers something like \$16,000,000." Verification of this has been attempted, but without success. Its probability is vouched for in the trade as judged by the experience of other industries. Reports of the March output of miscellaneous companies continues to indicate a considerable expansion, and tend to encourage the belief that the output will exceed 200,000,000 lb. per month in the near future. Refining costs are mounting and are causing considerable uneasiness. It is also stated that some of the small producers have formed a committee to present their grievances as to the growing costs and small profits at Washington. Government prices of 23.50c. for carloads, and 24.67½c. for less, continue to control distribution, which is regulated by the Copper Producers' Committee, who seem to be giving satisfaction to all concerned.

TIN

The situation is as unsatisfactory as ever. Offerings from the other side are now almost nil, and, as a consequence, business has been light. Buyers also are not as anxious to purchase as they were, but the few offerings that have been made have brought out extraordinarily high prices. The change in the attitude of buyers is thought to be due to certain happenings at Washington, but reports as to just what is going on there are conflicting. Consumers have been called to Washington this week, and each day meetings are being held between the Government and the various branches of the consuming trade. It is rumored that the object is a discussion of means to conserve the supply of tin, but many believe that there is something more radical than this back of the matter. Until this is entirely cleared, the market will probably remain quiet, and eagerness to buy will gradually subside. For spot tin the quotation now is 87c., New York, which represents what it would be sold for under fair or reasonable conditions. An interesting news item is that a representative of a South American tin refiner has appeared in New York and says that he has 100 to 150 tons of tin on the way to this country, assaying 99.86% tin.

and that there will soon be available 500 tons per month. Arrivals to date total 265 tons, with 5000 tons estimated as afloat. The London market is higher, with spot Straits quoted at £323 10s. against £319 10s. a week ago.

LEAD

The only event of the week that had any bearing on a rather lifeless market was the reduction last Thursday, April 11, of the quotation of the American Smelting & Refining Co. to 7c., New York, from 7.25c., which had obtained for some time. The outside market has also declined as a result to 6.95c., New York, or 6.80c., St. Louis. Very little business is reported at any price. The market seems to have before it a little more lead than it can absorb at present, and the situation is a narrow and restricted one, with the tone easy. The position of the large producers is unchanged. The large independent producer, the St. Joseph Lead Co., is still shut-down because of labor troubles. It has been closed now for four weeks. This lessens the offerings of lead considerably. Spot lead is quoted at 7 to 7.12½c., New York.

ZINC

For a time at least the market seems to have reached its low level. Opinion is divided as to whether or not it will go lower. There is not much expectation of an advance for some time. Prime Western for early delivery is lower than last week, the quotation being 7c., New York, or 6.75c., St. Louis. Sales have been made at 6.80c., St. Louis, for April-May delivery, and at 6.87½c., St. Louis, for May-June-July delivery. These about represent the market for the past five or six days. Demand is only fair, and sales have not been large, though each day lots of 100 tons have changed hands. The reports on stocks and output for the first quarter of this year show a slight increase in stocks on March 31 as compared with December 31, 1917, or 64,000 tons against 60,000 tons. The rate of production has not declined as much as expected.

Sheet zinc is officially fixed at 15c. per pound.

ANTIMONY

Demand is of small proportions, even that of the Government not being large. The quotation for Chinese and Japanese grades, duty paid, New York, is unchanged at 12.75 to 13c., New York, for prompt and early delivery.

ALUMINUM

For No. 1 virgin metal, 98 to 99% pure, in lots of 50 tons, 32c. per lb. is the Government price, with 32.10c. fixed for 15 to 50-ton lots, and 32.20c. for 1 to 14 tons, all for prompt or early delivery.

ORES

Antimony: A little business is reported done at \$1.75 per unit, New York.

Manganese: The U. S. collier 'Cyclops', which has evidently been lost, carried a large cargo of manganese ore from Brazil. A scarcity of ore suitable for making manganese alloys, no matter what the standard, is predicted in the trade to be certain within three to four months. It is believed that domestic-ore interests cannot deliver the quantity promised the Government. This is based on work done so far in the past.

Molybdenum: Business is difficult because molybdenite has been placed on the conservative list. The quotation is nominal at \$1.80 per lb. of MoS, in 90% concentrate.

Tungsten: Prices are unchanged at \$24 to \$24.50 per unit in 60% concentrate with activity somewhat less than for a week or two. Ferro-tungsten is unchanged at \$2.25 to \$2.40 per lb. of contained tungsten, with the market quiet.

Company Reports

PREMIER (TRANSVAAL) DIAMOND MINING CO., LTD.

Property: diamond mines and works near Pretoria, Transvaal, South Africa.

Financial Statement: profit during the year ended October 31, 1917, was £800,919 (\$3,845,000), and balance for distribution to the Union government (60%) and company (40%) was £757,046 (\$3,633,000).

Development: the 410-ft. level is being opened. Average depth of open-cut working is 249 ft. Reserves of diamondiferous ground above 360-ft. level are 27,000,000 loads (1600 pounds).

Production: 5,080,232 loads of 16 cu. ft. each, yielding 0.184 carat per load, or a total of 906,341 carats.

Costs: on a per-load basis, 50 cents; on a per-carat basis, \$2.72.

Natives employed numbered 5751, who were paid 74 cents per day; and whites 440, who received an average of £304 (\$1440) per annum.

IRON SILVER MINING CO.

Property: mines at Leadville, Colorado.

Operating Official: George O. Argall, general manager.

Financial Statement: total income was \$326,109 in 1917, of which \$293,889 was from ore sold. Operations cost \$269,698, plus \$14,838 special expenses. Excess of income over operating charges was \$41,574, less equipment depreciation \$20,106. The depletion charge of \$21,468 left no profit for the year. Surplus at beginning of year was \$368,187, and at end \$268,187.

Dividends: two paid last year absorbed \$100,000.

Development: total new work covered 7626 ft. Results failed to reveal the presence of additional ore in the older mines. The Moyer was worked out, while the Tucson is approaching that point. The new Marian mine is likely to be a good producer. The Mikado shaft here was enlarged to 15 by 5 ft. from 1000-ft. level to 1135 ft. Stations were cut at 1000, 1075, and 1125 ft., and pumps installed at the shaft-bottom. On the 1000-ft. level a large body of medium-grade zinc sulphide was cut. To further develop contiguous ground, a 5-year lease was taken on the Alleghany property of 19 acres. Lessees produced 25% of the ore.

Production: zinc-lead sulphide, zinc sulphide, iron oxide and sulphide, copper sulphide, zinc and lead carbonates, and manganese ores mined totaled 40,074 tons. This yielded as follows:

Metal	Quantity
Gold, ounces	689
Silver, ounces	163,493
Lead, pounds	1,893,020
Zinc, pounds	13,342,256
Copper, pounds	26,914
Iron and manganese, pounds	5,956,671

NORTH STAR MINES CO.

Property: gold mines and mills at Grass Valley and Nevada City, California.

Operating Officials: A. B. Foote, general superintendent.

Financial Statement: during 1917 gold extracted was sold for \$1,337,014. Interest, etc., amounted to \$37,410. Operations cost \$720,424 at the North Star and \$240,045 at the Champion, plus \$61,582 for improvements. Property purchase cost \$31,401. Balance at end of 1916 was \$910,864, and carried forward to 1918, \$979,836. This is mostly cash and investments, including \$250,000 of Liberty Bonds.

Dividends: two of 10% equalled \$250,000, making \$5,337,040 to date.

Development: the North Star production came chiefly from stopes above the 3000, 3400, and 4400-ft. levels. New openings covered 3216 ft. Nothing was done below 4400 ft. depth. Results were generally satisfactory, reserves being maintained. Of the ore broken, 25,974 tons was waste.

Results obtained or indicated prospects at the Champion are not very encouraging. Most of the ore came from the 2700-ft. level. New work amounted to 2495 feet.

Production: this was as under:

Mine	Tons	Value per ton
North Star	100,500	\$11.43
Champion	41,650	4.52

Of the total gold extracted, 82.06% was by amalgamation and 17.94% by cyanidation; this is at the North Star. Residue is estimated at 40c. per ton.

Costs: these were \$1.15 per ton higher than in 1916. The main items in the total of \$7.188 were \$4.629 for mining, 61.1c. for milling, 45.8c. for cyaniding, and 53.5c. for development.

The Central mill and cyanide plant were re-arranged, and now includes sixty 1500-lb. stamps and treatment section doing the work formerly done by two 40-stamp mills and separate cyanide plants. Capacity is expected to reach 9000 tons per month.

BINGHAM MINES CO.

Property: Dalton & Lark mines in West Mountain district, Salt Lake county; Victoria mine, Tintic district; Eagle & Blue Bell mine in Tintic district; and Yosemite mine in West Mountain district, all in Utah.

Operating Officials: Imer Pett, general manager; William Owens, superintendent of Eagle & Blue Bell; Joseph Hyland, superintendent of the Bingham properties.

Financial Statement: net earnings of Dalton & Lark mines, and royalties, amounted to \$150,015; plus dividends on shares of Eagle & Blue Bell and Victoria, \$365,788, making a total of \$515,802 for 1917. In 1916 the net income was only \$185,760, and in 1915, \$197,923. Construction and mine depletion reduced the 1917 income to \$431,303. Surplus at end of 1916 was \$400,224, and at end of 1917, \$644,028.

Dividends: two, No. 1 and 2, amounted to \$187,500.

Development: in the Dalton & Lark group, new work totaled 3670 ft. The Brooklyn mine shows a productive vein above the Mascotte tunnel for 800 ft. in length, extending to 1600-ft. level, a distance of 400 ft. on the dip of the beds. This is copper and lead ore. General results were good.

In the Victoria mine, operated through the Eagle & Blue Bell No. 1 shaft, the best results were in workings above 1050-ft. level at south end of property. Considerable lead-silver and dry silicious ores were opened between 1200 and 1300 ft. depth.

Exploration in the Yosemite mine was disappointing.

New openings in the Eagle & Blue Bell mine amounted to 4783 ft. Many new discoveries of ore were made, some of which are small and of low grade, but are promising. Production from the 1550-ft. level proved this section to be the best in the mine.

Production:	Dalton & Lark	Victoria	Yosemite	Eagle & Blue Bell
Ore shipped, dry tons	25,776	13,543	839	34,457
Gross value	\$334,668	\$243,909	\$13,227	\$1,068,837
Gold, ounces	1,872	2,875	36	2,819
Silver, ounces	139,241	338,751	5,047	519,880
Copper, pounds	679,007	119,553	11,005	4,089
Lead, pounds	1,681,848	515,993	121,776	9,069,091
Net profit	\$150,015	\$144,933		\$491,807

Book Reviews

Metallurgical Calculations. By Joseph W. Richards. Pp. 675, index. McGraw-Hill Book Co., New York, 1918. For sale by 'Mining and Scientific Press.' Price, \$5.

A one-volume edition of Dr. Richards' well-known book is before us, bearing the imprint 1918. The old text has been carefully revised and corrected, and useful physical and chemical data have been added. New features consist in tables of thermo-chemical constants for assisting in the prediction of undetermined heats of formation, the estimation of many latent heats of fusion and vaporization of the elements useful provisionally as first approximations, and the evaluation of vapor-tension formulas for the elements in both liquid and solid states. The work is a standard for all students of metallurgy, and this new and revised edition, condensed into a single volume, will be extremely welcome.

The Chemist's Pocket Manual. By Richard K. Meade. 3rd edition. Pp. 530. The Chemical Publishing Co., Easton, Pa., 1918. For sale by 'Mining and Scientific Press.' Price, \$3.50.

The third edition of this well-known and exceedingly useful vade mecum for the chemist contains important additions applying to problems connected with chemical engineering, a branch of technology that has developed so rapidly in this country within the last three years, and there has also been a large extension of the treatment previously given to analytical chemistry, so that the book has now become two and a half times as large as when it originally appeared. The increase over the second edition is 87 pages; these bear especially upon the needs of chemical industry as developed under the spur of war. The book has taken its place in the affections of the chemical student, and this new edition will prove of even greater value than the earlier editions.

Chemical Annual. Fourth issue, revised and enlarged. Edited by John C. Olsen and M. P. Matthias. Pp. 686, index. D. Van Nostrand Co., New York, 1918. For sale by 'Mining and Scientific Press.' Price, \$3.

It is four years since the previous edition of this handbook was published. During that period there have been many additions to the science of chemistry, and this work has been brought up to date. Molecular weights and factors have been re-calculated, and physical constants of the chemical elements and compounds (240 pages) revised. New tables include those on properties of the elements, calibration and true volume of glass vessels, use of indicators, properties of oils, alloys, etc., specific-gravity tables, and the conversion of units of heat, electricity, and temperature. In the tables on physical constants of oils there is nothing on those oils used in flotation processes. A note on the chemists duplex slide-rule is of value, so are the problems in acid and gas calculations. The insertion of 93 pages, listing new books, between the subject-matter and index is not a good idea. However, the handbook will be found of considerable value.

American Lubricants. From the standpoint of the consumer. By L. B. Lockhart. Pp. 236, ill., index. The Chemical Publishing Co., Easton, Pa., 1918. For sale by 'Mining and Scientific Press.' Price, \$2.

The present war has been termed as one of applied science, in which gasoline and lubricants play extremely important parts. Lubrication of rapid or slowly-moving machinery requires more skill than is generally supposed, whether it

be a watch, 10,000-kw. turbo-generator, or planing-machine. It is essential that an engineer know the grade of oil he is using, its viscous nature, also from what base oil it was made. In this book he will find such matters discussed practically; also many tests on a variety of lubricants. Grease is used in increasing amounts for lubricating heavy machinery, also even for moderate-speed shafting and inaccessible parts. Graphite and mica are often mixed with grease to advantage. Animal and vegetal oils find a place in many plants, and are described. With the enormous expansion in the use of automobiles and internal-combustion engines, lubrication requires much study, but in this case the consumer of oil need not bother much, as the manufacturer has designed the system to take care of the high temperatures produced. Lubrication of electrical machinery, steam engines and locomotives, cotton mills, and the like, receive due consideration. Stress is laid on the fact that railroad and power-plant companies, which allow a fixed quantity of lubricants for the machines in use, make a costly mistake in so doing, as often their engine-men need oil badly and cannot get any. Seven short chapters on specifications for oils, and various tables conclude a book for every consumer of lubricants.

Official Year Book of the Commonwealth of Australia. Statistics for period 1910-1916. No. 10, 1917. Compiled by G. H. Knibbs. Pp. 1198, charts, maps, index. McCarron, Bird & Co., printers, Melbourne.

This interesting compilation covers everything pertaining to Australia, including its history to the part being taken in the War. With the tabulated matter is much readable explanation. The graphs showing progress in certain industries are instructive. Under the head of 'Mines and Mining' we find 50 pages. Gold shows a serious decline since 1903—£16,294,684 to £6,200,000 in 1917—and a decrease in all minerals from 1907 to 1909, a small gain to 1913, then another drop to the present time. There are about 70,000 men engaged in mining, against 113,000 in 1901. Australia is an important producer of tin—lodes, hydraulic, and dredging—also of bismuth, chrome, molybdenite, and tungsten, in addition to the common metals. Oil-shale being so prominent in the United States at present, it is interesting to note that immense deposits occur in New South Wales and Tasmania, but are not worked to any extent just now. Two special papers deal with eucalyptus timbers and oils, giving some interesting notes on the oils extracted and used for flotation purposes. All flotation is done in Australia by eucalyptus oil. The iron industry of the Commonwealth shows a gratifying growth. Government aid to mining in 1915 amounted to £120,000 (\$600,000).

Elements of Western Water Law (revised). By A. E. Chandler. Pp. 162, index. Technical Publishing Co., San Francisco, 1918. Price, \$2.50.

The author is president of the California State Water Commission, and of the California Irrigation Board, and is a well-known irrigation and water-right specialist. The book will be useful to all users of water for mining and metallurgical purposes, as well as for agriculture throughout the West, where water-rights are subject to conditions that have grown out of ancient usage in dry countries, where scarcity has necessitated the application of utilitarian rules quite unlike anything to be found in well-watered regions. The book discusses the early development of the doctrine of appropriation, riparian rights in the Western States, the law of underground waters, the doctrine of appropriation, loss of water rights, and then takes up water-right legislation, bases of commercial and co-operative irrigation enterprises, the acts known as the 'Desert Land', the 'Carey', and the 'Reclamation', together with

other matter of interest. It is well indexed, and is paraphrased in such manner as to make the data easily accessible for use as a manual.

Everyman's Chemistry: The Chemist's Point of View and his Recent Work Told for the Layman. By Ellwood Hendrick. Pp. 374, index, bibliography. Harper & Brothers, New York, 1917. For sale by 'Mining and Scientific Press.' Price, \$2.

The popular scientific treatises by Mr. Hendrick are well known. They have been justly accepted by the public with the enthusiasm that the public always displays toward scientific subjects when presented clearly and brilliantly, couched in simple terms, and emanating from a person that can speak with authority. The book is thoroughly scientific in the sense that the development of the subject is along scientific lines. A man knowing no more chemistry than is contained in this book would have a very broad outlook upon the constitution of the world in which he lives, and he would better appreciate the complexities of modern industrial life and the needs of the Nation in stimulating and maintaining production of the many important essentials in War as it is conducted today. This is in no sense a war book, but its bearing upon the struggle should be very great, because it will help men who are not familiar with chemistry to obtain a grasp of the chemical bases of modern industrial life. The volume discusses air and water, the halogens, sulphur and its compounds, phosphorus, arsenic, antimony, bismuth, the alkali metals, sand and clay, lime and magnesia, iron and steel, and many metals both common and rare. With special facility the author undertakes to elucidate the principles of organic chemistry, starting with the carbon molecule and the simple hydrocarbon CH_4 , from which he develops correctly the modifications that lead to the vastly complicated products of which there is no end. He promptly, however, comes to the practical application of organic chemistry in the discussion of olefins and acids, alcohol and some of its derivatives, fats, oils, sugar, starch, and gums. Cellulose and nitrogen compounds, the aromatic compounds, and the coal-tar derivatives constitute the remainder of the book, with the exception of some valuable appendices. In this discussion the author reveals the chemistry of the common things of life, such as industrial alcohol, soaps and their uses, cane and beet sugar, gums, varnishes, paints, bread-making, explosives, artificial silk, paper, benzol, picric acid and aromatics, and dyes. Any man with an ordinary high-school education will be able to read the book, and it is so delightfully written that it is a pleasure to read it. We would suggest that the technical men who happen to be identified with operations involving organic chemistry would find it a most useful and delightful means for reviewing the subject in the light of modern manufacture.

Victory Breads. 50 bread recipes; 50 practical suggestions; 50 economical dishes; for 50 cents. Compiled by Helen Rickard. Press of the W. H. Kistler Stationary Co., Denver, Colorado, 1918.

One of America's famous mining engineers has said that the world's three great cook-books were written by members of that profession. A new contribution to the cuisine literature of the War, 'Victory Breads', issues from Denver, Colorado, compiled by Helen Rickard, wife of a mining engineer. The volume is dedicated to Mrs. Thomas Beale Stearns, wife of the Food Administrator in Colorado. The initial recipe, 'Cornbread with No Wheat Flour', is from the scholarly pen of Mrs. Herbert C. Hoover, also the wife of a mining engineer. The other recipes are contributed by women whose names have more than a local significance. One of America's distinguished chemists recently stated

that the fact of the kitchen having been under the rule of woman since Garden-of-Eden days, and no great discovery having issued therefrom, proves the inferiority of the feminine brain. Now that women have begun to study chemistry, there is hope that this stigma may be removed from that portion of the race to whose hands has been entrusted the important duty of supervising the nourishment of the family. Meantime 'Victory Breads' points out how the women of America may help, in the fateful struggle in which our country is engaged, by 'intelligent, earnest, and persistent food conservation.' This duty will be made more simple by frequent consultation of this booklet of dependable recipes sent forth by patriotic women for the benefit of the American Red Cross. The suggestions given will be of genuine assistance in complying with the mandates of the Food Administration and with the dictates of one's conscience, a help toward getting back to essentials; not the simple life of the man "wearing sandals and simple raiment, a raw tomato held firmly in his right hand", to which Chesterton jestingly refers, but to the practical wholesome fare to which thoughtful persons conform in order that those who are offering their lives for our freedom may have the food necessary to their sustenance. Let us pray: "Give them this day their daily bread", and let us relinquish it joyously to our defenders, nourishing ourselves with the substitutes—corn, on which the entire American continent depended (and it supported vigorous warriors by the thousands) until the coming of the European; oats, the national food of the hardy Scotchman; rice, the mainstay of the Japanese, a nation so warlike as to command world-wide respect; barley, a strength-giving food for both man and beast. All these cereals, with the addition of rye and emmer, we may use freely, sacrificing only wheat. Neither are we stinted in the use of potatoes, a tuber that has nourished a race so aggressive as that of the Emerald Isle. Indeed, our war diet would seem luxurious living in many countries. It recalls the priest in his poverty-stricken desert parish, who received from his bishop a printed list of foods he might use during the Lenten season. To compensate for lack of meat he might have fish, nuts, milk, chocolate, and many delicacies unknown to his frugal region, dainties that would have made a mockery of his fasting. With 50 war-bread recipes from which to choose, as offered by 'Victory Breads', the housewife will have no difficulty in maintaining variety. The practical advice, 'Learn to Use Beans', is followed by numerous recipes for their preparation. Among the Mexicans beans are known as the poor man's friend. They, with the corn tortilla, are literally the staff of life in the southern republic, and have been for ages. The plea for the use of the banana is sane. It plays an important part in the diet of the warm countries, and is one of the most nourishing and easily digested foods known to mankind. A remarkable menu is 'A Meatless, Wheatless, Heatless, Butterless, Sugarless Luncheon'. This title suggests a 'luncheonless luncheon', but it turns out to be a luncheon so dainty and satisfying that it may be considered a banquet by many citizens of our own United States, showing that not sacrifice but change is all that is asked by the Food Administration. If frugality be change, it will prove beneficial; groaning tables make groaning stomachs. The recipe, 'A Whole Dinner in One Dish' is so modest as to come within the limitations of the purse of any one who can afford to eat at all. The mother of many children will find useful the recipe for 'Everlasting Gingerbread'. To give it in this review would be to defeat the purpose of the volume. 'Victory Breads' closes with recipes for soaps, for white-wash, for baking-powder, for yeast, for preserving eggs, and finally with blank pages for your own original recipes. Buy it; you will find it useful to you, while the half-dollar will go to help save the life of some brave soldier. Copies can be secured from Mrs. Forbes Rickard, 950 Lafayette St., Denver, Colorado.

SPELTER production is responding to the lower price of the metal, the output in the first quarter of the current year being estimated by Mr. W. R. Ingalls, according to the 'Boston News Bureau,' at 136,000 tons, compared with 153,296 tons in the last quarter and 183,150 tons in the first quarter of last year.

OUR correspondent at Victoria gives a summary of the policy adopted by the government of British Columbia in regard to the taxation of mines during the period of the War. The tax is to be based on income or on 2% of the assessed value of the ore removed, whichever be the greater. Depreciation up to 15% is allowed. Gold-mining companies are to be taxed only on their profit, in recognition of the fact that the price of gold is fixed.

UPON another page we print the speech made by Capt. R. Hodder-Williams at the War Smoker of the Institute during its meeting at New York last February. We obtained the text of this speech from the current bulletin of the Institute. Capt. Hodder-Williams is a British officer in charge of training the students of Columbia University. We would like to have heard the speech; it is a pleasure to publish it, for we know that it will be appreciated.

THE selection of Ferdinand Foch to command the Allied armies and of Charles M. Schwab as commander-in-chief of our shipyards suggests how little indicative of national allegiance a name may be. The casualty lists of the British army, of the French, and of our own, of course, prove that a German name need not indicate either birth in, or allegiance to, the enemy country. It is said that Von Mackensen's name was corrupted from Mackenzie!

READERS of this paper will welcome the article by Mr. P. B. McDonald, whom they will recall as a former member of our editorial staff. Mr. McDonald is now on the faculty of the University of Colorado, helping a propaganda in which we are keenly interested, namely, the proper use of the official language of the United States, particularly when employed to convey ideas current in the technology of mining and metallurgy. His article on the expansion of a mining com-

pany's activities, or the productive continuance of a good organization, deals with a subject on which we have had something to say more than once. He gives point to his remarks by referring to individual examples of this policy and we shall be surprised if his article does not elicit some useful discussion.

HOW work in behalf of the Liberty Loan has caused business-men to drop their own affairs, in order to attend to a national duty, is shown by the marked decrease of mail-matter during the past week. Most of the outstanding men of business in all our principal communities have devoted the major part of their time to soliciting subscriptions, incidentally smoking out the slacker and the enemy-alien, of whom one is about as bad as the other.

TECHNICAL science in its peaceful aspect is bound to suffer from the War; that is one of the minor sacrifices to be made for a great cause. For example, the writer of the article on the Arroyo gold-mining district, Mr. E. H. Clausen, is now a captain in the Engineer Officers Reserve Corps in training at Camp Lee, Virginia. The response made by mining engineers and metallurgists to the call of their country has been splendid, as we know by the hundreds of men that have sent us either their change of address or the unavoidable cancellation of their subscription. We are proud to number so many good citizens among our supporters. On the other hand, their places have been taken by older men, above the draft age or otherwise unavailable for military service, and to these we give a friendly welcome, because they also are doing what they can to sustain the Nation in its purpose.

REPORTS of the Federal Reserve Bank, which are made monthly, show a total stock of gold amounting to 3050 millions of dollars at the end of March. Of this quantity the requirements for a reserve against outstanding paper is approximately 1150 millions, leaving 1900 millions of free gold, in the bankers' sense of that term. The ratio of gold reserves to net deposit and Federal Reserve liabilities combined is 60.8%, while the ratio of total reserves to these items is 62.9%, as compared with respective percentages of 82.7 and 84.8 a year ago. It is interesting to note that the curve of living-

costs reached its pinnacle at the same time as the high point in the total gold reserve. Living-costs receded slightly during May, June, and July 1917, but they composed the same index-number this month as obtained a year ago. Relative abundance of gold, therefore, does not wholly explain the cost of commodities, although its influence is indisputable. In connection with these barometers of the commercial world, the recovery of the market quotations on the leading industrial stocks is notable, these having risen from an average low mark of 63 last December to 79 in March. Railroad securities have not similarly responded, but the market price of these represents manipulation to a degree that does not obtain with regard to other stocks. Bank clearings, which may be taken as a measure of earning power through the movement of money, thereby indicating an off-set to the cost of living, show an increase this year, to the end of March, of 20.3% over those for the same period in 1917. This includes returns from 93.6% of the banking institutions of the country.

'HUNDRED per cent' is the slogan now among the organizations of business, meaning that every employee is expected to subscribe to the Liberty Loan. We are glad to say that our own staff has come up to the mark, but we find a more remarkable example set by the United Verde Copper Company, at Jerome, Arizona. Every one of its 2144 employees is a subscriber to the Loan. The company has assisted subscription by agreeing to advance the money required for the purchase of the bonds, permitting the men to pay for the same in five or ten monthly payments. The entire personnel of the company was organized into separate units, such as the mine, smelter, railway, tunnel, and improvement departments, with a consequent honorable rivalry to make a good record. In the mine each foreman worked for a record, the result being 100%. The distribution of nationality is interesting: American, 392; Canadian, 18; English, 18; Irish, 53; Scotch, 5; Welsh, 4; Mexican, 401; Spanish, 68; Portuguese, 5; French, 3; Italian, 57; Dutch, 1; Scandinavian, 21; Russian, 21; Finnish, 8; Serb, 32; Greek, 3; Slav, 96; German, 1; Austrian, 60; Bulgarian, 7; miscellaneous, 6. Considering the large proportion of aliens, the performance is unusually creditable. It sets an example that, we hope, will be imitated at every mine and smelter when the next loan is issued.

THAT high prices tend to retard consumption, thereby enabling us to send more commodities to our Allies, as stated by Mr. Richard Hoadley Tingley in an article published elsewhere in this issue, is an incontrovertible fact. The argument might be extended logically to the justification of profiteering, which has been a dominant influence in the elevation of market quotations on many necessities. That evil emerged instantly at the outbreak of the War, and it was the prime reason for interference by the Government. High prices at that time certainly were not due to over-abundance of money, nor to the operation of the natural law of supply and demand. Only in minor degree did they reflect a warranted antici-

pation of an approaching shortage. The upward surge was a direct response to the opportunity for easy graft. Price-fixing may be conceded to be an evil also, but in that particular case it was the lesser of the two, and it is a valuable corrective when properly used. Except for authoritative restriction the market would have swirled to an insane height, causing infinite harm. It must be noted, furthermore, that high prices alone do not encourage economy. It is when prices rise without a corresponding increase in wages that consumption is reduced. The wage-earners represent the vast majority of the population, and their emolument has reached an unprecedentedly high level. Consequently the cost of commodities has been paralleled by an enormous increase in the purchasing power of the people. The chief danger from price-fixing, as we stated when it was first proposed, consists in undertaking to discriminate between commodities. Such is the inter-relation of industries that a market disturbance affecting a few articles is soon felt by all. If some remain free from control while others are fettered, the restricted industries inevitably must suffer. That is what has happened, and consequently the production of many needed supplies is curtailed. The principle of democracy and of sound business is to apply one rule to all. In times so abnormal as these no reliance may be placed upon the spontaneous operation of economic laws. The Government has been forced to protect the public against profiteering, but it should avoid the imposition of unequal burdens and restraints, while the supplies needed for the exigencies of war, both here and abroad, should be commandeered at the established rates.

OPINION at New York and Washington forecasts an increase in the fixed price of copper from the present figure of 23½ cents to the higher level of 25 cents per pound. Apparently the market is discounting this decision. The refiners of the metal claim that they are losing money on existing contracts and are compelled to raise the charge for treating blister copper. The big producers of copper assert that miners are being paid on a basis of 27 to 28 cents per pound for the metal, and that not only have wages advanced disproportionately but the prices of the materials used in producing copper have risen from \$4 to \$14 per hundred pounds since the War began, that pig-iron has risen from \$14 to \$33 per ton, and that the conditions of the market render logical the fixation of the price of copper at 25 cents. Few of the big companies, it is stated, are making a profit of 8 cents per pound; some of them are making no more than 6 to 7 cents per pound net. That does not sound convincing to the average citizen; for the matter of that, the arguments of special interests at this time are clouded by profiteering, which is the chief sin of business against the national and allied cause, the cause, as we believe, of civilization in its largest and highest sense. The purpose of any fixation of price is to restrain speculation in a necessary war-material and yet to stimulate production. Will 23½ cents suffice for the purpose? It is said that the smaller producers and those exploiting low-grade ore re-

quire a higher price in order that their operations may be fruitful. If that be so, it will be well to accord the necessary stimulant of a higher price while, at the same time, demanding an increasing national share of the big profits made by the more profitable mines. One fact must not be overlooked: while the production of copper in the United States is increasing, the supply coming hitherto from South America, notably from the Chile (Chuquibambata), Braden, and Cerro de Paseo mines, is decreasing, owing to lack of shipping. Taxes are heavy already, but they are inequitable, especially the excess-profit tax. What is needed is a regulation such as will stimulate necessary industry while at the same time preventing a few individuals from enriching themselves unduly at the expense of the Nation. It can be done.

The World's Gold Production

The statistics of gold production usually available early in the year are now to hand, so that it is possible to estimate the total output of gold in 1917. Such an estimate necessarily includes a guess as to about one-seventh of the total, although this fact is obscured in the elaborate figures published by various authorities. The United States and the British dominions furnish fairly accurate figures promptly, but other countries are slow in issuing statistics, sometimes postponing them for two years or more. However, the English-speaking countries produce 86% of the total output, so we are able to make a general estimate near enough for our purpose, which is to consider the status of the gold-mining industry. It will be noted that last year in every case the production declined. The principal contributor, the Transvaal, shows a decrease of \$5,631,000, which, however, is relatively small, being less than 3%. In itself it is not significant, because the production last year was about equal to that of 1915 and a million dollars more than in 1913, the year preceding the War. That the gold-mining industry of the Rand is at its zenith of gross production and already past its zenith of profitability is certain, but the decline may not be made manifest in statistics for several years, thanks to the expansion of the eastern end of the great goldfield. In the adjoining province of Rhodesia the decrease was about 10%. Toward the close of the year several discoveries of ore underground galvanized the market for Rhodesian shares, but there is no reason to anticipate any real accession of vigor to the gold-mining industry of a region that has been victimized by share-peddling and financial chicanery. In West Africa—the Gold Coast—the decrease was also about 9%, the two chief producers, the Ashanti Goldfields and the Prestea, particularly the latter, showing signs of decadence. The Indian output of gold, which comes entirely from the Kolar goldfield, exhibits only a slight decrease, but the one lode that is being mined by four successful British companies is lean in the bottom workings and it is only the large quantity of ore in reserve that enables the mines to maintain a uniform output. A serious collapse is inevitable within a few years. The bulk

of the Canadian production comes from Ontario, and predominantly from the Porcupine district, which in 1917 yielded \$8,229,774, the average yield being \$7 per ton. Of this total the Hollinger Consolidated Gold Mines contributed \$4,233,777, or more than half. In the United States the yield shows a decline of about 8½% as compared with 1916 and of over 16% as compared with 1915. California continues to be the foremost producer, yielding \$20,815,900 in 1917, but in this State, as in every other except Arizona, there was a small decrease. Colorado's decrease was \$3,240,000 and California's \$1,160,000. Arizona advanced from \$2,092,800 to \$5,533,800, and the increase is significant because it was due to the production of gold as a by-product in the winning of copper. Whereas 66% of the gold produced in the United States in 1915 came from quartzose ores and 25% from placers, it is probable that in 1917 this proportion, making together over 90% of the total, decreased 6%, while on the other hand the yield from copper ores increased from 6% in 1914 to 10% in 1917. The report of the U. S. Geological Survey on this phase of the industry is not yet available for any year later than 1915, so these estimates are only reasonable guesses, but they serve to indicate an important trend in gold production, namely, that an increasing proportion of the output, in the United States in particular, and in other countries also, is being derived from the exploitation of base-metal ores, principally copper, but including lead and zinc ores as well. The Australasian output has been decreasing steadily for many years, owing to the exhaustion of the big mines in Western Australia and the decline of the older goldfields in Victoria, without an adequate corrective from fresh discoveries. Last year the total diminution in Australasia was a little more than 17%, which is a serious proportion. It is impossible to give an accurate estimate of the production of gold last year in Russia and Mexico, both these countries being in a state of anarchy rendering statistical inquiry out of the question. The guesses given in the accompanying table probably err on the hopeful side, for conditions in Russia be-

	1917	1916	Decrease
United States ..	\$84,456,600	\$92,590,300	\$8,133,700
Canada	15,449,426	19,234,976	3,785,550
Transvaal	185,871,016	191,501,929	5,630,913
Rhodesia	16,952,462	18,892,258	1,939,796
West Africa	7,420,388	8,134,234	713,846
Australasia	35,275,000	42,584,188	7,309,188
India	10,744,882	11,183,061	438,179
*Russia	20,000,000	31,000,000	11,000,000
*Mexico	10,000,000	12,500,000	2,500,000

came so much worse during the closing months of 1917 that systematic mining operations on a large scale ceased abruptly; the gold to be produced this year will have to come from small mines and from the depredations of unorganized mobs upon the workings of the richer properties, such as that of the Leskoie. It is evident therefore that the world's gold mining industry was hard hit last

year, by the abnormal cost of labor and supplies, by political disorders, and by the continued depletion of the bigger mines. It is probable that the decrease of yield during the current year will be fully \$50,000,000, the statistical data for the first quarter of the current year indicating a continued decline in the British dominions, while in Russia any systematic mining is impossible pending the restoration of some form of orderly government. In Mexico the outlook is better, but precarious. Everywhere the cost of labor and supplies continues to increase; the priority given to war orders hinders the equipment of new mines or the maintenance of machinery in good order at old mines. We are facing a world-wide decline in gold production.

The Pittman Silver Act

The enactment, by Congress, of legislation to regulate the purchase of silver has had an immediate result highly gratifying to the miner, for silver is established at the dollar mark. Secretary McAdoo, in his letter to Senator Pittman, recited the main facts: that more silver was required in order to settle foreign balances, instead of attempting to stabilize exchange by methods that involved future adjustment by means of gold, which is greatly needed at this time as a base for the huge structure of credit created by Government loans. Therefore 350,000,000 of the silver dollars stored in the Treasury will be converted into bullion. The stock of such dollars is 490,000,000, containing 375,000,000 ounces of fine silver, all represented by outstanding silver certificates. These are to be retired as the dollars are taken out of the Treasury and in their place Federal Reserve bank-notes of various denominations (including those of \$1 and \$2), will be issued. Of these notes only \$11,670,000 worth is in circulation as yet. It is interesting to note that silver certificates have disappeared from circulation to a considerable extent, and it is open to question whether the necessary quantity of these certificates will be available as fast as needed for carrying out the purpose of the Act. Concurrently the Treasury is authorized to replace the silver thus used, for exchange and export, by the purchase of bullion on the market at \$1 per fine ounce, coining this new metal into standard dollars. In this way the large accumulation of silver, occupying 40,000 cubic feet of space in the Treasury and weighing 12,880 tons, becomes available for war service. It is probable that the Government's purchases will absorb the entire output of silver from mines in the United States. The season of maximum export from Japan and China is now at hand and silver will be needed by American importers to pay their balances to the Orient; therefore the passage of the Act is timely. In March \$9,946,351 in silver bars was shipped from San Francisco and in April \$7,000,000. The advancing price of all commodities produced in the Orient has given the people of India and China an enormous increase of purchasing power, enabling them to convert their surpluses into silver as never before. That factor gains in importance from the circum-

stance that freight and insurance across the Pacific from this coast are considerably less than by the usual route from New York and London by way of the Mediterranean and the Suez Canal, where the submarine menace has raised the insurance against war-risks to a prohibitive figure. These abnormal conditions have called for special legislation. The Pittman Act is a war measure, not an experiment in bi-metallism; its object is to make use of the silver lying inert in the Treasury.

Further data will be timely. No silver dollars have been coined since 1904. About 20,000,000 ounces was purchased by the Mint last year to make half-dollars. The standard dollar contains $412\frac{1}{2}$ grains of silver, its value being based on a gold equivalent of \$1.2929 per ounce, so that with silver at \$1 the seigniorage is 22.7 cents. The silver-value of subsidiary coins is 6.46% less, hence there would be a seigniorage, or profit on minting, even if silver stood at \$1.30 per ounce. In other countries the seigniorage is even larger. The United States produced 74,244,500 out of the world's total production of 170,000,000 ounces last year. The increased demand for silver has been due to a variety of causes. An appreciation was inevitable when gold was withdrawn from circulation by the belligerent nations and silver became the principal metallic currency in daily use. In Mexico successive revolutions and persistent disorder caused a decrease in production from 87,000,000 ounces in 1911 to 30,000,000 in 1917. Meanwhile India enjoyed a series of good harvests and accumulated a big credit-balance with the warring countries of Europe. This called for silver. Exports to India raised the price of silver, but a crop failure would cause a commensurate drop, upsetting exchange. Hence the desire of the British government to stabilize silver, and thereby the rupee. The Indian demand for silver in 1916 was met by heavy exports from China, causing wild speculation, with restriction of trade. In September 1917 silver rose to 108 cents, a large export from San Francisco having developed. Thereupon the United States placed an embargo on export to China, except under license, and at the same time the British government restricted the shipment of silver to the Scandinavian countries. By that time the entry of the United States into the War, and the increased war expenditure of the British government in Asia, owing to the employment of Indian troops and the campaign in Mesopotamia, had intensified the scarcity of silver, previously induced by the subsidiary coinage required for the payment of European armies. The high price prompted the offering of old silverware, and the melting of coins, many of which became "more valuable dead than alive," but both of these sources of supply proved too small to check the intensified demand. The use of silver in the arts is increasing; in 1915 it was 29,891,271 ounces, an increase of 6,000,000 over 1908. This is due largely to the cinema business, which is expanding. Thus new conditions rendered imperative some co-operation between the American and British governments in order to stabilize silver and to ensure a sufficient supply for the exigencies arising from the War. That has been done.

DISCUSSION

War Excess-Profit Tax

The Editor:

Sir—There is one aspect of this tax upon which I have seen little comment in the mining journals, namely, the effect of the tax upon speculative enterprise. The risks must have commensurate rewards if speculative undertakings are to be continued, but, in general, this tax diminishes the rewards about half (the tax is 60% on all profits over 33%) on the more speculative enterprises. In other words it doubles the risk for the same reward.

An illustration of the effect of this tax in a hypothetical, but common, condition of affairs is interesting. In developing certain classes of mining prospects a reasonable assumption would be that the risk is such that an average of ten prospects have to be developed to make one mine. The one mine must then pay back the capital spent on all ten before any return can in reality be considered as profit. Continuing, let us say that a man, in connection with his other business, spends a period of ten years in developing prospects. He spends \$90,000 in developing nine prospects that are of no value, but he still persists, and in the last year he spends \$10,000 on a prospect, makes a mine of it, selling it to an operating company for \$200,000. To the mining man the 100% profit as a reward of many years of endeavor, loss of interest, and risk assumed, would seem modest, in fact, not particularly attractive. As I understand the law, however, the Government assumes for purposes of taxation that he has made a profit of \$190,000 on a capital of \$10,000. His excess-profit tax plus his regular income-tax would then be considerably over \$100,000 and instead of making something he would have been taxed out of any reward for his time, energy, and persistence over a period of years, together with the confiscation of a goodly part of his capital of \$100,000.

I may be wrong in my interpretation of the law, but I can find no provision, in such a case as the above, allowing him to write off the losses incurred in the prospecting of previous years against the profit of the year in which the tax is levied. Even if the interpretation of the law allows him his actual capital investment of \$100,000 the war excess-profit tax would be \$47,000, his ordinary income-tax would be something over \$5000, so he would have left a profit of about \$48,000 for a ten years endeavor. He would have made as much as if he had invested in some stable bonds with practically no risk attached. Risky and speculative undertakings are not conducted for such rewards and in my own experience I note an increasing disinclination of capital to

engage in such enterprises under the present handicap of drastic taxation. In fact, this tax has already stopped much of the developing of prospects into mines and will be more effective in this way when its meaning is more fully understood.

One does not complain of this tax where it is really what it sets out to be, a tax on excessive profit, and is levied on the extra profit created by war conditions, but development of mines, oilfields, and other opportunities for steady industries to follow was slow enough, from the point of view of the welfare of the country, without this extra burden; with it, I fear, a period of stagnation for many desirable industries is approaching rapidly if not already here. We need the development of our resources in practically all forms of mining both during and after the War. "The prospect of today is the mine of tomorrow."

Let us have some public consideration of this question by other engineers, and, if the law as it stands is to the detriment of our country's welfare, let us see if it can be amended so as to bear only where it purports to bear, and does not stifle industry. I suggest an open discussion of the question.

E. W. STEBBINS.

San Francisco, April 22.

Iron and Steel Technology

The Editor:

Sir—In the March issue of 'The Mining Magazine' (London) there is an editorial calling attention to the fact that the American Institute of Mining Engineers in its transactions continues to make a specialty of iron and steel papers, although an American Iron & Steel Institute was formed some years ago. This criticism will, I am sure, meet with approbation from hundreds of members of the American Institute of Mining Engineers. Iron and steel technology forms a specialty which requires all of the time of an engineer to master and hence the iron and steel men can more naturally group themselves together in a special institute, thereby relieving the transactions of the American Institute of Mining Engineers of a raft of papers interesting only to the iron and steel men.

H. W. TURNER.

San Francisco, April 8.

[This is a debatable subject. We have long questioned whether the separation between coal, iron, and steel, on the one hand, and the non-ferrous metals, on the other, would not have to be recognized. We shall be glad to see the subject discussed in these columns.—EDITOR.]

Simplified Price-Level Economics

By RICHARD HOADLEY TINGLEY

The old 'quantity-of-money' theory of prices will not down. Many still cling to the notion that the more money we have, be it gold, or silver, or uncovered paper, the higher price-levels will mount automatically. We have more money in the country than we ever had before. Our currency issues amount to \$4,896,801,905. This is just about \$48 per capita. It is almost exactly \$10 more than it was a year ago. Here is the seat of the trouble; this reveals the reason why prices are constantly rising; that is what the 'quantity-of-money' theorists say. If this is not reason enough, they aver, look at the existing ratio between currency and gold. Of the \$4,896,801,905 in paper money afloat, only \$2,363,636,860 is represented by gold, or about 48%: the other 52% represents inflation.

The rise in price-levels can be accounted for easily enough if we forget all about the 'quantity-of-money' theory that is so constantly being held before our eyes. Some of the banking institutions that think it their duty to lead the uneducated mind into right lines of economic thinking are not inclined to let us forget the danger involved in an over-supply of gold, or an inflated currency, or apparently easy credits, but the over-supply of gold and the inflated currency have not yet produced a condition of easy credits, nor are they likely to do so. The only state of easy credits that has yet been discovered in our present abnormal financial condition is that the United States government seems to have all the credit it wants. Its people think so, at any rate, as evidenced by the unprecedented sums of money they are lending now. Here is the seat of the misconception. It is the United States that is being expanded through her easy credits, not her people in commercial life. The United States is being expanded (inflated, if you like) and her people are doing it for her, and doing it willingly, while their own private transactions in credits are on a most reasonable and normal basis.

Inflation in the credit of a nation engaged in financing the gigantic enterprise in which the United States is now occupied is an obvious necessity. Two blades of grass cannot be made to grow where formerly there was but one, without extraordinary exertion. This extraordinary exertion by our Government has made an inflation in credits imperative. A currency issue of a much larger amount will soon be just as necessary if the War lasts long enough. It may reach even \$75 or \$100 per capita. But it will reach neither figure unless it is demanded as a war necessity. We have not yet succeeded in making two blades of grass grow where formerly there was but one, but we are on the way, and the thing will be done. In the meantime, and until we have accomplished this feat, war has materially lessened

our supply of 'goods and service.' A large portion of our goods and service, formerly consumed at home, is now being consumed by our European allies. When the supply of goods and service is lessened, prices rise. Gold and currency have nothing to do with it. As the home supply diminishes, the demand increases, and, naturally, higher prices follow. High price-levels have a tendency to retard consumption. It is necessary that our home consumption of commodities be retarded to enable us to send more commodities to Europe. Therefore, high prices are a necessity until we have learned how to make two blades of grass grow where formerly there was but one.

Price-fixing is an experiment that is being tried by our Government, in the hope of doing what? Of tending to bring about a condition that will make for lower price-levels? Surely it cannot be that the Government wants to bring about a lower level of prices now. A lowering of price-levels would automatically stimulate home consumption of goods and services so badly needed for export to Europe. It cannot be that the Government wants to do this.

All the finely drawn theories of political economy fall to the ground when tested under the conditions that now face us. Theories of 'quantity-of-money' and 'rapidity-of-circulation' may be well enough for the class-room. Their study is good mental gymnastics, but until we have finished that little job of making two blades of grass grow in the place of one, high and mounting prices are an economic necessity. The law of supply and demand, if left to do its work without hindrance, will see to it that prices do not come down. Home consumption will thus be retarded. Should the price-fixing policy of the Government produce a condition that will tend to keep prices from further rise, and, sympathetically, make for a reduction in price-levels in some instances; then will an invitation be automatically sent out that will stimulate home consumption. Then it may be necessary that we turn our attention to making three, instead of two, blades of grass grow where formerly there was but one.

LEAD SULPHIDE ore, containing silver or copper, may be treated as follows, according to a method recently patented by Robert de Lucc. The ore is ground, and the lead sulphide decomposed by a hot solution of FeCl_3 , leached with a 12% solution of FeCl_3 at a temperature of 90° , or with some other solution having a similar solvent action on PbCl_2 . The copper and silver are electrolytically deposited, using iron or lead anodes. The solution is then electrolyzed in a diaphragm cell with steel cathodes and carbon anodes to deposit the lead and regenerate the solution for leaching fresh charges of ore.

Should Mining Companies Expand?

By P. B. McDONALD

To assert that the mining of a definite orebody is a process of exhausting assets is a truism. To avoid the ignominious ending of a skilled organization many mining companies acquire new properties. They argue with a good deal of truth that a going company, having its corps of technical workers and its necessary apparatus, stands at an advantage in the testing and development of prospects. It has often seemed a pity that, because of the exhaustion of an orebody, an organization of capable men should be disbanded and scattered. What is sometimes lacking is initiative or imagination; again the fear of making a mistake and spoiling a good record inhibits the moving spirits from taking chances. Sometimes they are right in deciding to close the chapter and read the obsequies, for it is better to do so than to blunder badly. A study of the methods of prominent mining companies during recent years reveals all shades of opinions and policies concerning expansion, from the decision of the short-lived but profitable Seneca-Superior Silver Mines, Ltd., to write 'finis' on its books, to the vigorous expansive ramifications of such operators as the Calumet & Arizona Mining Co. and Tonopah Mining Co. In contrast with such progressiveness is to be mentioned the peculiar lack of imagination sometimes shown by a dominating company in its own district, such as the indifference of the United Verde Copper Co. to the possibility of new orebodies during the years in which it was the sole operator at Jerome. When a large and prosperous mine is the principal attraction in an out-of-the-way district, its management is apt to assume a deprecating air regarding further prospecting in the neighborhood, implying that their company, in its never-failing wisdom, would know all about other orebodies if any existed.

It is interesting to review the short history of the Seneca-Superior Silver Mines. This company, in which the moving spirit was W. E. Segsworth of Toronto, had an eight-year lease on a high royalty upon a small tract adjoining the property of the Nipissing Mines Co. at Cobalt. For several years the developments, mostly under a lake, were discouraging. Then, in the four years from 1913 to 1916, over \$2,000,000 was produced, of which \$1,579,817 was distributed in dividends, or 326% on the capital of \$500,000. The vein was then exhausted, and the prospect for finding others was discouraging; so the company decided to wind up its affairs. A different course, such as other Cobalt companies have chosen, would have been to look for new leases or options, for example, at Porcupine, but the company decided to let well enough alone. Several of these companies, as their ore-reserves dwindled, sought new mines elsewhere. After the wonderful richness of the Cobalt veins, some

of their ventures seem disappointing. La Rose Consolidated Mines Co., after exhausting the ore of the La Rose, Princess, Lawson, University, and Fisher-Eplett claims at Cobalt, took options on a copper mine in New Brunswick, on the Hurd gold mine at Kirkland Lake, and on the Maidens-MacDonald gold mine at Porcupine. The results to date have not been encouraging. The La Rose company has paid in dividends an amount practically equal to its capital stock, namely, \$7,500,000.

The Crown Reserve Mining Co., which has paid \$6,190,849 in dividends on a capitalization of \$2,000,000, produced principally from its original holding of 23 acres under Kerr lake, has received several hundred thousand dollars in dividends from the Porcupine Crown Gold Mining Co., in which it owns 60% of the stock, but the latter appears to be a short-lived mine, with no very rosy future. The Crown Reserve also tried financing the Newray Mines Co. at Porcupine, a re-organization of the much advertised Rea Consolidated Gold Mines, but finally abandoned it. The Crown Reserve relinquished options on the property of the Globe Consolidated Mining Co. in Trinity county, California, and on gold claims at Boston Creek, Ontario, after the developments had proved disappointing. A 90% interest in the Reward mine, in Inyo county, California, was purchased; this is a small mine, equipped with a flotation plant, assured of a return of capital and a fair profit; however, the gross returns are likely to be only several hundred thousand dollars. Other Cobalt companies that are entering new fields include the Beaver Consolidated Mines, which, like its neighbor, the affiliated Temiskaming Mining Co., is selecting prospects at Kirkland Lake, Porcupine, and Cobalt; the Mining Corporation of Canada, a British organization, which has examined and turned down a great many widely-scattered North American prospects, but which is making a large production of silver from its several mines at Cobalt; the Dominion Reduction Co., operating the Nova Scotia silver mill, and owning the rich Croesus gold mine 50 miles east of Porcupine, as well as other interests; the Coniagas Mines, which has paid \$8,440,000 in dividends on a capital of \$4,000,000, and which controls the Redington Rock Drill Co. and Mines Water Supply Co., and has paid \$20,000 for the Maidens-MacDonald gold mine at Porcupine, besides owning a silver smelter at Thorold, Ontario.

The prosperity of the companies at Cobalt has been one reason for their willingness to branch out, but perhaps the very richness of the Cobalt veins, as already suggested, has made their ventures elsewhere seem disappointing. Nipissing, with the biggest and best holdings at Cobalt, has been a conspicuous example of a pros-

perous company that is not interested in acquiring properties in other districts. The reason probably is that Nipissing has plenty of territory for prospecting within its own confines, for it has 846 acres containing over 100 veins. Undoubtedly when a favorite dividend-payer begins to take chances on other prospects the stock market takes a pessimistic view of the matter. Such has been the case with the Calumet & Arizona Mining Co. Its stock was more favorably regarded in the markets before it commenced to expand than after it began financing the New Cornelia Copper Co. and agreed to spend \$100,000 in the exploration on the Gadsden Copper Co. at Jerome. Yet New Cornelia has been a distinct success, for the 76% of its stock owned by the C. & A. was acquired at \$1.76 per share, as compared with a present market-value of about \$16, and dividends from New Cornelia will soon add considerably to the parent company's income. The psychology of the matter is, probably, that buyers of shares like to figure on a self-contained mine where as many complicating factors as possible have been obviated. The Calumet & Arizona is a company with the best reason in the world for expansion; it is favorably situated in a mineral region of great richness with the peculiarities of which it is well acquainted; its staff possesses energy, good judgment, and adaptability; and its owners have initiative, imagination, and large resources.

The Tonopah Mining Co. of Nevada is an excellent example of a moderate-sized mining company that has expanded successfully. On a capital stock of only \$1,000,000 this company, besides its 160 acres at Tonopah, owns 83 1/4% of the Tonopah Placers Co.; 55% of the Eden Mining Co.; 92% of the Tonopah Canadian Mines Co. of Manitoba; besides shares in other subsidiaries. The Tonopah Placers Co. operates three gold dredges near Breckenridge, Colorado, where the average yield, in 1916, was 12.7c. per yd., and the cost 7.2c., the revenue being \$406,368, on which the net profit was \$73,529, exclusive of depreciation on property and plant. The Eden Mining Co. has nine square miles in the Piz Piz mining district of Nicaragua, where a body of gold ore assaying \$12 per ton has been found and partly developed. The Mandy Mining Co., a subsidiary of the Tonopah Canadian Mines Co., has a promising copper property near Schist lake, north of The Pas, Manitoba, on which 20% ore has been disclosed in a lens 200 ft. long. The Exploration department of the Tonopah Mining Co. existed for five years, from 1912 to 1917, and J. E. Spurr was in charge; the total cost was \$261,108 and the total value of results is reckoned to be at least \$8,000,000. This example is a good argument for a prosperous mining company that sees its reserves declining, to engage a capable geologist and acquire new properties.

The Guggenheim companies present a pronounced example of expansion. To analyze their complicated and interlocking interests would require the services of a certified accountant. For instance, the Kennecott Copper Corporation owns the Kennecott Mines Co., including the Bonanza and the Jumbo copper mines near Kenne-

cott, Alaska, the 195-mile Copper River & Northwestern railroad from Cordova to the mines, the Beatson Copper Co.'s holdings on Latouche island, the Alaska Steamship Co. operating between the Tacoma smelter and the mines, 99% of the stock of the Braden Copper Mines Co., which owns mines in central Chile, 434,504 shares out of 1,624,490 issued of Utah Copper Co., which, in turn, owns slightly over 50% of the stock of the Nevada Consolidated Copper Co., and the Bingham & Garfield railroad with 111 miles of track; and many other properties. The affairs and assets of the American Smelting & Refining Co. are even more intricate and far-reaching. It mines, smelts, and refines gold, silver, copper, lead, and zinc, and manufactures them into sheets, rods, tubes, white lead, zinc white, sulphuric acid, and other things. It mines coal, and smelts tin, it owns ten railroads in Mexico, refines bismuth, cadmium, arsenic, nickel, platinum, palladium, selenium. The amount of metals produced by it in 1916 included: copper 394,719 tons; lead 279,144 tons; silver 71,868,451 oz.; gold 2,662,011 oz. The reason for combining such diverse interests would seem to be that the directors prefer to offset occasional disappointments by balancing them against successes; and then, too, the financial jugglery incident to these operations probably appeals to men so skilled in the game.

The Yukon Gold is another Guggenheim organization. Its holdings include 650 placer claims in the Klondike valley, 24 claims in the Iditarod district, Alaska, various placer areas in California on the American, Feather, Trinity, Yuba, and Butte rivers; a lease on property of the Coeur d'Alene Mining Co. near Murray, Idaho, and lode claims in the Jarbidge district of Nevada. These lode claims, under development by the subsidiary El Roro Mines Co., are estimated to have 214,000 tons of \$15 gold ore blocked out. The Yukon Gold Co. has seven large dredges at Dawson, two at Iditarod, five in California, and one 7 1/2-cu. ft. dredge in Idaho; yet the operations of this company have not realized expectations. From a high point of \$8.50 in 1909 the stock has declined in the market to about one dollar per share. In its disappointment the Yukon Gold Co. can be compared with the Alaska Gold Mines Co. of the Hayden-Stone-Jackling interests, or with the Alaska Juneau Gold Mining Co. of San Francisco. Many stockholders of Alaska Gold Mines bought their shares at \$40, which will bring now only about \$2 per share, yet the Hayden-Stone-Jackling interests have not only picked a number of winners, of which the Utah Copper is the most notable, but they have not shown the disposition of the Guggenheims to combine good mines with poor ones in the same corporation.

It does not help an unsuccessful mine to combine it with another weak one, and it seems a pity 'to wish a lemon' upon a good property. Combinations do not always bring economies. On the other hand, it is a commendable policy for a company that finds its ore-reserves dwindling to acquire new property, particularly if its staff is capable. If the staff is incapable or the luck bad, things are apt to go wrong.

Possible Sources of Barium Carbonate

By SAMUEL H. DOLBEAR

It is important to stimulate prospecting for witherite, the natural carbonate of barium, and the new hypothesis here given may lead to further discoveries of this material. The only ore of barium produced in the United States until recently has been barite, which is the normal sulphate of barium. The residual deposits in Missouri have yielded by far the most important quantities, but it is not my purpose to discuss these or other residual deposits. A few years ago the Leona Chemical Co., of Elmhurst, California, undertook experiments in the manufacture of barium compounds, using barite from a deposit near El Portal, Mariposa county, California, as a source of barium. At the surface the ore was fairly pure barium sulphate. Further development of the mine showed a gradually increasing amount of barium carbonate, and on the lower levels, about 250 ft. vertically below the outcrop, witherite, in the form of a white ore of fine texture, was found, carrying in excess of 90% BaCO_3 . The only associated minerals that I observed were pyrite interspersed through much of the ore in variable amounts, and some manganiferous material not intimately contained in the ore itself, but occurring in vugs or narrow veinlets. It is notable that the pyrite showed at the most only slight traces of oxidation. The barite-witherite vein cuts a belt of gneiss, which comes into contact with the late-Jurassic granites of the Yosemite a few hundred feet farther north.

The key to the hypothesis which I present lies in the fact that the upper part of the vein is rich in barium sulphate, and that it gradually gives place to carbonate as depth is attained. I appreciate that the advocates of the theory that barite was deposited from descending solutions may point out this fact in furtherance of their belief, accounting for the upper zone of sulphate by the fact that barium sulphate is less soluble than the carbonate, and would therefore be deposited first. Barium as sulphate is relatively insoluble in either magmatic or in aqueous solution. Its presence in nature as a silicate is rarely recorded, nor does it combine readily with other acid radicals, with the exception of carbonic acid, to form the minerals of commerce. It seems probable, therefore, that the primary ore in the El Portal deposit was barium carbonate. Oxidation of sulphide minerals, both in the ore itself and in the enclosing rocks, would result in the formation of sulphuric acid, which would readily convert the carbonate to sulphate. This would continue to whatever depth such acidic solutions might penetrate, or until the acid had been completely neutralized. If the volume of acid is sufficient to completely alter the carbonate, then, of course, no witherite would be present. The small amount of oxidized material in the El Portal

deposits indicates that erosion has kept pace approximately with the oxidation.

At the Hatton manganese mine near Aguila, Arizona, barium carbonate is associated with the ore, and at one point it nearly replaces it as a vein-filling. As the manganese ore is residual, embedded in unconformable sandstones, the relation between the two minerals is not

HATTON MANGANESE MINE, AGUILA, ARIZONA

genetically important, the barium being of later deposition and probably related to nearby acid igneous intrusions through the sediments. The association of barium with manganese ores in many Arizona deposits, however, is characteristic, and justifies closer study.

At the Bardin mine near Hollister, San Benito county, California, the barium sulphate occurs as irregular lenses in limestone. Analyses of ten samples taken from the surface show traces of barium carbonate. This example, however, I regard as a type of a residual deposit.

It is not conceivable that it could have been altered from carbonate to sulphate, as at El Portal, without also forming a considerable body of associated gypsum. Hill* refers to occurrences of this type as replacement deposits.

Barite is nearly always associated with sulphides or their resultant oxides. It is not probable, therefore, that witherite may outcrop at the surface, owing to its ready affinity for acid solutions derived from the zone of oxidation. Barite deposits should, therefore, be prospected at depth for witherite. Deposits so prospected should, of course, be large enough so that if witherite is found, it would be likely to exist in generous amounts. Closeness to rail transportation is another important factor. Deep oxidized zones should be avoided. In regions of fairly rigorous climate, with resultant active erosion, the presence of sulphides or the absence of oxides in considerable amounts should be noted. The deposit to be tested must be in veins, and the existence of acid igneous intrusives close by may be found to be significant in some cases.

With these rather crude guiding factors at hand, it is necessary to prospect the vein in depth, which may be done by any of the usual methods, such as core-drilling, sinking prospect shafts, or driving adits if the topography permits.

USES. If barium carbonate could be found in sufficient quantities in Nature, it would replace the sulphate in the manufacture of barium chloride, nitrate, and other salts. Its direct uses as a carbonate are, however, rather limited. Barium nitrate is in great demand during the War as a constituent of 'green fire' used in signaling. With the exception of small amounts of barium carbonate produced intermittently at El Portal, our entire supply is imported. Refined barium carbonate has been quoted during the past year at about \$50 per ton.

FUEL-BRIQUET PRODUCTION of the United States during 1917 was 406,856 net tons, valued at \$2,233,888, an increase over 1916 of 111,701 tons, or 38% in quantity, and of \$788,226, or 55% in value, again breaking the record of the previous year. According to C. E. Leshner, of the U. S. Geological Survey, the demand for fuel was so strong throughout the whole year that there was no lack of market to limit the production of the briquet manufacturers. Despite the increased cost of binders and of manufacturing, most of the plants operated to full capacity and reported a prosperous year.

FERTILIZERS of all kinds will henceforth be subjected to Government control through the operation of an executive order for licensing the importation, manufacture, storage, and distribution of sulphuric acid, sulphur, phosphate rock, acid phosphate, basic slag, sodium nitrate, ammonium sulphate, cyanimid, calcium nitrate, potash salts, cement dust, blast-furnace dust, wood ashes, and all other fertilizer ingredients. The chairman of the committee having charge of this matter is Charles W. Merrill.

Selective Flotation in Australia

The highest grade of zinc concentrate being produced at Broken Hill is being turned out by the Bradford sulphur di-oxide selective flotation process, according to recent advices from Australia. The 65th half-yearly report of the Broken Hill Proprietary, Ltd., for the six months ended November 30, 1917, discloses the fact that slightly over 50,000 lb. of slime was put through the Bradford mill during the period, producing some 5600 tons of concentrate assaying 61.6% lead, and 83.2 oz. silver, and 13,400 tons of zinc concentrate. Since the re-flotation section of the mill was started the average grade of the zinc concentrate has been 49.54% zinc, 4.34% lead, and 14.47 oz. silver.

Several of the other large mining companies at Broken Hill have had the process in use for over a year, the Australian rights having been purchased in 1917 by a combination of four of the heaviest producers—Amalgamated Zinc, Zinc Corporation, Broken Hill South, and Sulphide Corporation. It is our understanding that the treatment of the Broken Hill Proprietary ore does not involve the use of oil, emulsification being accomplished by the use of nitre-cake. The selective agent is SO_2 gas in acidulated solution. Both galena and blende become thoroughly wetted by agitation with the SO_2 solution, and sink, the galena then coming to the surface while the blende is kept in the wetted condition by the incipient chemical action of the sulphurous acid, being more susceptible than the galena. Pyrite follows the galena, the separation between iron and zinc being quite as well defined as between the lead and zinc. The Broken Hill crude ore runs approximately 15% lead, 15% zinc, and 14 oz. silver.

Several American, Canadian, and Mexican lead, zinc, and copper ores have been sent across the Pacific for testing at the Broken Hill mill during recent months, and preliminary reports just returned from Australia indicate the applicability of the SO_2 treatment to certain refractory ores on this side. The Bradford selective flotation processes are patented in all the principal countries of the world, Mr. Bradford's representative in America being Guy Riddell, recently returned to New York from Australia, and in Washington as consulting metallurgist to the United States Tariff Commission.

LOUISIANA, as might be supposed from its geographical position, receiving, as it does, the delta sedimentation from a great continental drainage basin, possesses a remarkable variety of clays. Almost every sort required in the industrial and decorative arts is to be found in that State. The U. S. Geological Survey has recently issued bulletin 660-E, dealing with these resources.

SODIUM ACETATE is in active demand, with the market practically bare of available supplies. The by-product charcoal makers are unable to meet the present requirements for acetates of any kind. Acetate of soda, for dyers' use, is now selling at 16 to 18c. per pound.

Commercial Aspects of the Shale-Oil Industry

By J. H. G. WOLF

The possible development of the shale-oil industry in western America as a means of augmenting the crude-oil supply is attracting much attention. The timeliness of the subject is undeniable because of the ever-widening demand, both for purposes of war and of peace, and because of the apparent inability of the oilfields of the United States to fully meet the increased need of petroleum products. Preliminary estimates show that this country consumed (inclusive of its export trade) 390,000,000 bbl. of crude oil in 1917, but produced only 335,000,000 bbl. The deficiency of 55,000,000 bbl. was met by drawing 20,000,000 bbl. from stocks and by importing 35,000,000 bbl. from Mexico.

The second reason for the manifest interest in oil-shale lies in the accredited existence of enormous reserves of such shale areas in the Western States, having a higher average oil content than the shale treated for oil abroad. Having the two conditions necessary for the development of an industry satisfied, namely, the fixed demand for its products, and the abundance of the raw material with which to operate, we may look forward with confidence to early developments of importance. Competition with natural crude oil would be impossible if the oil were the only product from the shale; at least that is true at the present prices. A market must be developed also for the ammonium sulphate that can be produced as a by-product in the distillation of the shale.

During the recent hearings at Washington before the Public Lands Committee of the House, on the pending Mineral Lands Leasing Bills (S. 2812 and H. R. 3232), which measures are to open, on the leasing principle, the remaining oil, coal, and phosphate areas on the public lands of the United States, delegates appeared from Utah, Wyoming, and Colorado, urging the necessity for considering, at the same time, the shale-oil problem, as there is now no specific law for acquiring title to these particular lands. Rights to shale land are being initiated under the placer-mining laws. Having in mind the unhappy experiences of the oil-land operators with this inept and archaic law, it is natural that those fostering the new industry should fear a repetition of the experience of the oil men with that statute.

It is necessary, also, to sound an alarm of another character. Among those who appeared for the oil-shales at the aforesaid hearings was one public official, Russell D. George, the State geologist of Colorado, whose testimony seems worthy of more than passing notice. Mr. George gave, on February 26, the benefit of 10 years' study and observation of the shale-oil industry and its possible development in the Western States. With true scientific and economic interest in the subject he fearlessly asserted that, regardless of promoters' claims, the only possible hope for commercial success lay in con-

ducting operations on deposits yielding not less than 50 gallons of oil per ton of shale, and that these must be upon the very largest scale, with capital in ample volume, and with technical skill of the highest order. The crux of his testimony was that no operations of less than 1000 tons capacity per day, conducted under the best physical conditions, could hope to succeed at present, and that such operations would require an initial capital expenditure amounting to upward of \$2500 per ton per day capacity, or \$2,500,000 for a completed and running plant. That figure did not include a sulphuric-acid manufacturing plant for the refinery, which might add \$300,000 to the sum, but it did presumably include the cost of opening a deposit of shale for mining operations upon the scale stated. The figures of Mr. George were corroborated by Arthur L. Pearce, an oil-shale technologist, who followed, and who spoke from 40 years experience abroad. The importance of such testimony may be realized when it is considered that oil-shale enterprises are being proposed, and some are reported actually under construction, planned for such limited capacities as 100 tons per day, and with a capital equipment of only \$75,000 to \$100,000 each. These, as pilot plants, will serve a beneficial purpose. Unless Mr. George views the situation and the requirements from too conservative a standpoint, there surely will be some financial and industrial wrecks on the highways of Colorado. Evidence was offered at the hearings, by a committee of the Utah section of the American Mining Congress, proposing cost estimates of \$750 to \$1000 per ton per day capacity as a basis for capital requirements, but unfortunately no minimum-quantity capacity-figures were included in the estimates. As substantiating the higher figures of Mr. George, the history of the Scotch shale operations offers an illuminating commentary. The works in Scotland reduce about 3,500,000 tons of shale annually, this being the output of six major plants. The industry was already established there when Drake drilled his first oil-well in Pennsylvania in 1859. In the 'seventies, as many as 50 different companies conducted the operations, which treated but 1,000,000 tons of shale annually, or about 60 tons each per diem. Today these 50 plants have been reduced (or consolidated) to a half dozen, while the output has been more than trebled, each plant treating 2000 tons per day. The margin of profit, even on that scale, is admittedly small. The Scotch shale is leaner than that of western America, but the operators abroad have the advantage of cheaper labor, and a larger by-product resources, that is, more ammonium sulphate, in addition to an exclusive oil market, because Great Britain has no natural oil deposits now known; and the market, moreover, is in the midst of a densely populated country. It is plain, therefore, that the capital expendi-

ture for a shale-oil plant must be on a scale not unlike that on which the 'porphyry' coppers of the West are conducted; the history of the Scottish industry, if correctly interpreted, confirms this fact unmistakably.

A further analysis, even superficially made and considered, of the elements that control oil operations on any basis gives warning to all who would venture hastily and insufficiently equipped within its province. It is a relatively easy thing merely to produce crude oil, a venture requiring only the wise selection of the right ground and enough capital to sink wells, because the bigger factor, the marketer and the refiner, will install the necessary pipe-lines and pump away the product. The producer's responsibility ends when he has got the oil on the surface. One hundred thousand dollars judiciously spent can frequently launch an oil venture in an average field. It is quite another thing, however, to be properly established in the oil business, which comprehends not only the simple matter of producing the crude staple, but the all-embracing enterprise of piping, refining, and marketing the finished products, wherein lie the bigger profits. Those who market as well as produce oil in California are capitalized as high as \$15,000,000 to \$100,000,000 each. While there are 300 oil-producers there are fewer than a half-dozen marketers. From the evidence obtainable it is apparent that to engage successfully in the shale-oil business the enterprise must consist not only in mining the raw material, but also in treating it by distillation, with a plant equipped to produce the oil and the ammonium sulphate, after which the crude oil must be refined and fractionated for its marketable products. Even then, without some marketing and distributing organization, including the many capital demands that it entails, an enterprise can fall just short of being a commercial success. Thus it appears that, to become properly established in the shale-oil business, the enterprise must have very nearly the same equipment as a natural-petroleum marketer, rather than that of a mere oil producer. Upon that premise the estimate that it will take \$2,500,000 adequately to launch a single unit in the business is not unreasonable.

Other observations in the testimony of Mr. George are worthy of careful consideration by those interested. The main points are as follows:

1. It requires a ton of water, in the manifold operations, to completely treat a ton of shale, and the shale deposits of western Colorado, southern Wyoming, and eastern Utah, embracing about 16,000 square miles of supposedly workable deposits, lie mainly at an elevation of 8000 ft. above the sea, where water is relatively scarce, and in a region famed for its aridity. The water-rights to the principal streams have, in a general way, long since been pre-empted. Engineering problems as well as technical problems of great magnitude doubtless face each new enterprise.

2. An oil-shale is not a mere container of residual oil; the shale is the depository of the remains of plant and animal life which, when distilled, yield hydro-carbons that associate in a form that make crude petroleum.

Crude oil, as such, therefore does not exist in the raw shale; it is produced upon the application of heat to the shale.

3. The shale deposits can be mined exactly as coal, where the overburden does not permit of stripping and working with the steam-shovel. Coal is produced in Colorado at a total working cost of \$1.18 per ton at the pit-mouth, and shale mining, though dealing with a tougher substance, should cost no more. The capital investment to open an ordinary coal mine amounts to 77c. per ton per year capacity; that of an oil-shale enterprise \$7.50 per ton per year, and no operations should be undertaken on less than 6000 to 7000 acres, or, say, 10 square miles of deposits. This means that it will require 40 association placer claims of 160 acres each to satisfy the requirements as to acreage for one complete enterprise.

4. There should be obtained, on an average, from the richer shale worked at the outset (that is, the 50-gallon per ton shale) an extraction of 85% of the oil, namely, of the oil-making or kerogen content, and 60% of the 41 lb. of ammonium sulphate theoretically available. Many new processes of extraction have been proposed, which are being tried in the laboratory and on a small-sized working-scale, but the obvious procedure in designing the reduction plant is to follow closely the technology as developed in Scotland and France; not that no room exists for improvement in the foreign practice, but that no new principles have been developed among the foreign operators in a generation. The improvements made have related to the modes of practice. The Scottish plants consume from 80 to 200 lb. of coal per ton of shale treated, while in America the combustible gases, which issue on retorting the shale, should, it is stated, supply the needed fuel. Owing to the greater thickness of our deposits, an acre of western American shale land is alleged to contain ten times the amount of extractable oil yielded by an acre of Scottish shale.

Upon the conclusion of Mr. George's testimony, Mr. Pearce added, in substance, that the shale-oil industry is a more highly developed and a livelier one in France than in Scotland; that Spain and Brazil are getting busy with the industry, as are also Australia and other countries. He asserted that, if it had not been for the developed industry in France, the Allies would have been seriously handicapped for toluol and other compounds needed for making high explosives; that the grade of oil obtained in reducing the shale was determined entirely by the manipulation, as the main trouble in retorting lay in the carbonization of the material, which prevents the heat from penetrating the charge; that there are practically no commercial by-products save the available ammonium sulphate, and that the ash, after being drawn from the retort, consists of absolutely nothing but plain clay and sand, and offers but little chance of recovering potash commercially as had been alleged by some. Finally he said that the capital required for operation on an adequate scale is enormous, and that the facilities and the technical skill must be provided on a commensurate scale.

MILL OF THE COLORADO MINING COMPANY, PHILIPPINE ISLANDS

The Aroroy Gold-Mining District

By E. H. CLAUSEN

The Aroroy gold-mining district, in the Philippine Islands, first came into prominence in 1911 when the Colorado Mining Co. erected a 20-stamp, all-sliming, cyanide mill, and soon after declared dividends from successful operation. In that year H. G. Ferguson wrote 'The Geology and Mineral Resources of the Aroroy District, Masbate,' for the Division of Mines of the Bureau of Science at Manila. It is the most complete geological report of the district yet written. Since then, several minor reports have been made by the Division of Mines, and C. M. Eye has also included this district in his article, 'Gold Mining in the Philippines,' which appeared in the MINING AND SCIENTIFIC PRESS, June 17, 1916. The Island of Masbate is in the middle of the Philippine archipelago. It is the eleventh largest island in the Philippine group, having an area of approximately 1200 square miles. It owes its unique two-pronged shape to the junction of the prevailing antielial trends of the Visayan islands and central Luzon. The eastern arm parallels the mountain ranges of central Luzon, Samar, Leyte, and eastern Mindanao. The western arm, which shows a change of direction of almost 90° from the eastern arm, parallels the mountain ranges of Cebu, Negros, Panay, Palawan, and western Mindanao. On the north-eastern end of the island, and north of the junction of these mountain

ranges, is situated the Aroroy gold mining district, which has an area of about 75 square miles. All work so far has been confined to a mineralized belt about two miles wide, and running in a north-westerly direction. This belt has been prospected, and located in part, from the seashore at Aroroy, inland for 10 miles.

Old workings have been found on the property of the Colorado Mining Co. These, according to the inhabitants, represent operations during the Spanish occupation. The fineness of the gold and the lack of high-grade ore, however, gave little encouragement for extensive work by crude methods. During and after the Spanish-American war, attention was attracted to the numerous quartz outcrops. W. Edelmaier, who entered the district in 1898, is, perhaps, the first American to do any prospecting here. Later, Andres Herbert and H. B. Berkenkotter discovered and opened the Colorado and Syndicate properties respectively, which are now the two largest gold producers in the Philippine Islands. Two gold dredges tried to operate in the district, but without success. Mining on an economical scale started when the Colorado Mining Co. built its 20-stamp cyanide mill under the direction of C. M. Eye in 1911. Previous to this, the Great Eastern Mining Co., now the Syndicate Mining Co., the Gold Bug property, and the Cogon Mining Co., all had erected

plants of 10 stamps, but they failed to make money, principally because amalgamation gave poor recovery of the fine gold, further interfered with by an excessive amount of clay in the ore. Since 1911 the district has developed rapidly, but not nearly as fast as it should, considering its situation and the difficulty of prospecting. It is at present the largest gold producer in the Philippine Islands. In 1913, the Syndicate, one mile south of the Colorado property, erected a 100-ton cyanide mill under the direction of H. C. Wilmot, formerly manager for the Colorado Mining Co. During the same year the Keystone Mining Co. constructed a 50-ton plant near Aroroy, and about two miles north of the Colorado mine, under the superintendence of A. C. Cavander. Since 1910 Mr. Schwab has been running a 5-stamp mill on small veins south of the Syndicate. In 1916 J. O. Enberg erected a 10-stamp amalgamation mill five miles south of the Syndicate, and is now developing a good prospect. In 1917 and 1918 O. L. Kettenbach erected a 5-stamp mill, of the Joshua Hendy individual-mortar type, one mile south of the Enberg property.

The island of Masbate is mountainous, and a large part is still unexplored. The Aroroy district mostly is heavily forested, and has a dense undergrowth. The ground that is not forested is covered with a heavy growth of cogon grass, the height of which varies from five to ten feet. A noticeable feature is that most of the mineral deposits are found in the forested area. Those deposits so far discovered in the cogon area are low in grade. The Lanang and Guinobatan rivers are the largest in the northern part of the island. They flow in a northerly direction from the central mountains and empty into Port Barrera. Except for a small area that drains into the sea along the east coast, the entire Aroroy district is confined to the watersheds of these two rivers. The Lanang river, which is navigable at high tide for a distance of three miles, is much used as a water-way for interior freight and supplies.

Ferguson states that the two cordilleras that form the southern boundary of the Aroroy district are in part composed of older sediments, largely slates, intruded throughout by large areas of diorites and more basic plutonic rocks, and associated with extensive later volcanic rocks of a rather basic type, ranging from occasional dacite, through andesite, to basalt and leucite, with accompanying pyroclastics. These mountain ranges he has classed as pre-Tertiary, and the sedimentaries as of Miocene age. In the Aroroy district few sedimentary rocks are found. In the Guinobatan canyon, on the Limestone claim of the Syndicate Mining Co., a small body of bluish crystalline limestone, named the Mountain Maid formation, occurs. Along the seashore bordering Port Barrera and just north of the town of Aroroy coral limestone containing many fossils is found. The rocks of the district, however, are almost entirely igneous, consisting chiefly of diorites, andesites, and andesite porphyries. These have been divided into the Aroroy quartz-diorite formation and the Panique volcanic series. Although mapped as the Aroroy quartz diorite, this formation con-

tains diorite, gabbro, and syenite. All deposits of value so far have been discovered in the diorite. Where the andesite and andesite porphyries occur, the ore deposits decrease in value and disappear. The diorite is of a bluish-green color, generally rather fine grained, with a granitic texture. It occurs as laccoliths throughout the central part of the area. On the east is a belt of granitic rock, called the Bolena granites or grano-diorites. A similar formation occurs on the western side of the district, on one large mountain west of the Lanang river.

The ore deposits, which are gold-quartz veins, are similar throughout the district, and are found always near or at the summit of the hills. This feature is so noticeable that prospecting is generally done on the apex of the outcrops. Commencing at the seashore at Aroroy, the various mining companies, named in order, each control a hill. The general strike of these hills is north-westerly. They are, Mt. Aroroy, Keystone Mining Co.; Mt. Bagadilla, Colorado Mining Co.; Mt. Kalakbao, Syndicate Mining Co.; Boston Hill, Schwab Mining Co.; Mt. Loia, Collett Mining Co.; Napwaunan Hill, J. O. Enberg; Belete Hill, Belete Mining Co. The veins in the northern part of the district, including the properties of the Syndicate, Colorado, and Keystone, strike N. 30° W., with a dip of 65 to 90° north-east. From Mt. Loia south, the veins strike from N. 70° W. to almost due east. The ore deposits are as a rule in a brecciated zone, composed of several quartz veins, with fillings of clay, or manganese, or both. The Colorado, which is typical, is mining from five different lodes and is developing two more. There are 15 parallel lodes from 100 to 600 ft. apart. The outcrop of lode No. 5, which has been worked for 1500 ft. continuously on the surface, can be traced about three miles. It is here and there as much as 100 ft. wide, the largest stope being 36 ft. wide. In places it has a beautiful banded structure, containing yellow and red clay seams, many quartz stringers, several bands of manganese oxide and quartz veins, together with a series of shear zones filled with brecciated quartz and manganese, or quartz and red or yellow clay.

The gold, which is not visible on megascopic examination, occurs in three distinct types: (1) a hard, white to cream colored, and sometimes bluish quartz, (2) a soft, spongy, friable quartz, (3) manganese oxide and quartz breccia, or a clay and quartz breccia. One of the lodes of the Keystone Mining Co. looks like the veins of the North Star mine in California, but has not given indication so far of persistence in depth. The Enberg and Belete properties have a hard bluish quartz vein impregnated with pyrite that has assayed as high as \$25 per ton, in addition to the lodes caused by shearing and subsequent vein-filling. Calcite is also found as a gangue mineral. Deposition from silicious circulating waters is common throughout the larger lodes. Many of the smaller quartz veins are in fissures and do not show the silicious deposition characteristic of the shear zones. Chalcopyrite and galena have been found in the country rock. The depth of the ore deposits has not yet been determined. All mining as yet is by means of adits. The Colorado mine,

which is now 800 ft. below the outcrop on the summit of Mt. Bagadilla, has the deepest workings in the district and is still in the oxidized zone. Whether the ore will be persistent in depth is doubtful. Almost all the lodes are rich at the surface and rapidly decrease in value and volume downward. This depth in the smaller veins is about 75% of the length of the outcrop. In the upper workings the ore of the manganese stopes averaged about \$14 per ton, while the same character of ore in the lower workings assays only \$3 per ton. However, the harder quartz in the lower levels in places has changed but slightly in assay value below the upper workings.

Prospecting is difficult, on account of the rainfall, excessive vegetation, and the oxidized nature of the ground. Bolo men are necessary to cut the trails through the tropical growth. In some places the field of vision is about 25 ft.; in others the undergrowth, while not so dense, is covered with creepers and palms and other vegetation that greatly impedes cross-country travel. Trench work is of little importance owing to the depth of the oxidation. The cheapest and most satisfactory prospecting is by means of adits at such a depth as to insure seeing the decomposed formation. The cost of such work varies from 25c. to \$1 per foot by contract, the company furnishing tools and powder. The Philippine mining laws are different from those of the United States. Any citizen of the Philippine Islands, or of the United States, is allowed to locate a mineral claim 300 metres square, but he cannot locate more than one claim on the same vein or lode. The side lines are vertical; there are no extralateral rights. Regulations for assessment work and patenting resemble the laws of the United States.

The average assay value of the ore now being mined is \$8 per ton at the Colorado mine, \$11 at the Syndicate mine, and about \$20 at the Belete and Napwanna properties. The largest operating mines are those of the Colorado Mining Co., with a capacity of 150 to 175 tons per day, and the Syndicate Mining Co. with a capacity of 100 to 150 tons. The Keystone Mining Co. is closed for lack of ore-reserves, due to insufficient development. The Belete and Napwanna properties can be considered at present only as good prospects. Both the Colorado and Syndicate mines are efficiently managed by men of broad experience. J. S. Colbath, formerly manager for the El Rayo Mining Co. in Mexico, is manager of the Colorado, and J. J. Shaw, formerly with the Mountain Copper Co. in California and the United Verde in Arizona, is manager of the Syndicate mine. Stopping methods differ in these two properties. The Colorado uses principally a modified stull system, with posts and filling, while the Syndicate uses square sets and filling. The deposits are similar. The Syndicate is troubled with many transverse faults, which displace the lode from 10 to 25 ft. The Colorado has only one fault with a 25-ft. throw. The faulting, however, does not determine the method of stopping and timbering. In the Colorado, caps are used up to 25 ft. in length, with posts about 7 ft. or less apart, depending upon the ground. Sets are

placed 5 ft. apart. Floors are 7 ft. high. The cap is placed in a hitch in the foot-wall, or on a post, and carried to the hanging wall as one piece. If the ground does not allow this, butt-caps are used as the work progresses. The average diameter of the caps and posts is 10 in.; round timber is used throughout. For lagging, round poles 4 in. diam., and either 6 or 12 ft. long, are

AROROY IS ON MASBATE ISLAND

used. The ground is often heavy, and the walls bad. All work is done by picking. The stopes are carried up by overhand work on successive floors. Filling is kept within one or two sets from the back. This is run down from the surface, or from the upper old workings. The problem is generally to keep the ground from caving, for country rock is calcareous and impregnated with oxidized iron pyrite. On exposure this ground slacks and crumbles, leaving the walls insecure. Stulling, un-timbered stoping, and top slicing with casing, are also used in the district, depending on the nature of the deposits. Powder is seldom used except to loosen some hard ground.

Contract work is found to be the most satisfactory. Payment is generally made by the car, delivered to the ore-bin, or by the foot of advance, per foot of stope width on one floor, one set deep; that is, 7 ft. high and 5 ft. deep and 1 ft. wide, or else a fixed price per square foot. This may include delivery of the ore to the outside ore-

bins or to the chutes. While this cost is variable, the average price might be given as 25c. per 1000-lb. car, mined and trammed, or 45c. per foot of stope-width 5 ft. deep and 7 ft. high. All development is done by contract at a cost of 25c. to \$1.50 per foot for a 4 by 6½-ft. drift. Matteson half-ton cars are used. Larger cars cannot be handled by the Filipino labor.

LABOR

Efficient labor in the Philippine Islands is a serious problem. Laborers must be recruited from the soil, as the Filipino has done little or no mining. Furthermore, he has not the physique or stamina to do hard work. The average height of the Filipino is about 5 ft. 4 in. and his weight is about 130 lb. Each stope crew has a 'capataz,' or straw-boss, who oversees from three to ten men. Over these crews is generally another 'capataz' who has charge of one working level or more. Supervising this force is an American shift-boss. On account of popular superstitions it is difficult to obtain reliable night-shifts. Consequently, night-work is confined mostly to tramping and development work on contract. Stopping is done on the day-shift of nine hours. Common labor, trammers, shovelers, and miners are paid 50c. per day. Capataces, and a few of the better workmen, are paid 60 to 75c. per day. Japanese are used as carpenters and timbermen, and are paid \$1.50 to \$1.75 per day. A Japanese shift-boss is employed at one mine and a Japanese engineer at another. White shift-bosses and mill-men are paid \$180 per month. Other white skilled labor is paid \$125 or more. Food costs the Filipino about \$5 per month and the white help \$30 to \$35 per month.

Owing to the scarcity of good manglar wood for fuel, internal-combustion engines are replacing steam. The Syndicate Mining Co. has two 150-hp. English Mirrles engines, and is about to install a Busch-Schultzer unit. The Colorado Mining Co. has installed a 500-hp. McIntosh & Seymour Diesel engine. These have given good results. Fuel-oil is shipped from Burma or Borneo by the Asiatic Petroleum Co. by steamer direct to the mine landings. All oil has been shipped in drums, but owing to the lack of bottoms, future shipments are expected to be in bulk and pumped from the steamers to supply tanks on shore. Oil costs \$25 per ton.

The smaller mills of the district use stamps and amalgamation. The Syndicate mill is a 140-ton all sliming cyanide plant. The ore is supplied from the mine by a 1000-ft. gravity tram. A 3 by 15-ft. washer, formerly used as a dredge trommel, thoroughly washes the ore in solution, the fine passing to the Dorr classifiers direct, and the oversize from the ¼-in. screen is discharged into the mill-bin over a 1½-in. grizzly, by means of a 14-in. belt-conveyor. The grizzly oversize is crushed through a 10 by 16-in. Blake crusher and Sturtevant roller-jaw crusher and elevated to the mill-bin by a bucket elevator. From the mill-bin the ore is fed by gravity to a 6 ft. by 16-in. Hardinge conical ball-mill. The ball load is varied from 7000 to 9000 lb., depending upon crushing condi-

tions. Frenier spiral sand-pumps elevate the ball-mill pulp to two Dorr classifiers, the slime flowing directly to 30 by 12-ft. and 30 by 9-ft. Dorr thickeners placed in parallel. The classifier oversize is fed to a 6 by 16-ft. Abbé pebble-mill, which returns its product to the Frenier pumps, thus completing the cycle. Hard quartz from the mine is used as mill feed for the pebble-mill, on account of its cheaper cost and the difficulty in obtaining flint pebbles. The thickener-pulp is raised by diaphragm pumps to an agitator consisting of a 30-ft. tank in which a number of 6-in. pieces of pipe, each acting as an individual air-lift, are hanging from a revolving mechanism, similar to that of a Dorr thickener. This type of agitator was described in the MINING and SCIENTIFIC PRESS of July 19, 1913. The agitated pulp is filtered by Kelly filter-presses, and the pulp is discharged into the Guinobatan river. After passing a sand clarifier, the thickener-overflow gold-solution is precipitated in five wooden zinc-boxes. The bullion is shipped to the United States Mint at San Francisco, California. The recovery is about 93%. The 20-stamp all-sliming cyanide mill of the Colorado Mining Co. was the pioneer mill of the district. This consisted of a 10 by 20-in. Blake crusher, twenty 1250-lb. Traylor stamps, two Dorr duplex classifiers, three 5 by 18-ft. Traylor tube-mills, five 15 by 28-ft. Dorr thickeners, and a locally made Moore filter. The mill when erected included two 12 by 40-ft. Pachuca agitators, and two 11-ft. Oliver vacuum filters. These were discontinued soon after the erection of the mill. In order to treat economically the large amount of low-grade ore in the mine, the original mill was entirely re-built during the latter part of 1917, at a cost of \$50,000, under the management of J. S. Colbath, and I served as superintendent of construction.

The present mill is a compact plant, consisting of a 10 by 20-in. Blake crusher, which discharges into a 1000-ton mill-storage bin. From the mill-bin the ore is fed to a 50-ton automatic feeder, which furnishes a steady feed to a 5 by 6-ft. cylindrical ball-mill. The ball-mill product is raised by a bucket elevator to a Caldecott cone. The overflow from this cone goes to a Dorr duplex classifier, and the discharge to a 5 by 18-ft. Traylor tube-mill, whose product is returned to the Caldecott cone. The oversize from the classifier is fed to a second 5 by 18-ft. tube-mill, which returns its product to the cone. The overflow from the classifier is run to three Dorr thickeners, one acting as a primary thickener, and two as secondary thickeners. The thickener underflow goes to two 12 by 30-ft. Pachuca agitators, and then to a Butters filter. The gold solution from the thickeners is clarified in a canvas vacuum-filter. The gold is precipitated in five wooden zinc-boxes. The bullion is shipped to the Selby Smelting & Lead Co. at San Francisco.

The Aroroy district still presents opportunities for prospecting and investment, but the present development of the district does not offer chances for mining on a large scale. Mining in the Philippine Islands, however, is still in its infancy.

Classification of Furnace-Slags

By HERBERT LANG

For purposes of study and comparison, to reach results of higher utility, various classifications of slags have been made, based for the most part on internal characters, or upon peculiarities of production. They are classified in the first place in accordance with the predominant acid constituent, whence we have silicate slags, phosphate slags, aluminate slags, titanate slags, and fluoride slags, which are characterized by the chemical compounds bearing the respective names. Sometimes slags are labeled 'acid' or 'basic', the reference being to chemical composition, the first term signifying a predominance of the acid member, and the second that of the base. They are classified also in accordance with the special metallurgical process in which they are produced, such as 'iron' slags, 'copper' slags, and 'lead' slags. Ordinary furnace slags are essentially mixtures of silicates of various bases and of different degrees of acidity, in which they are dissolved as accidental and usually unrelated substances. When these accidental substances begin to predominate in a given slag it receives the name of the new chief component, the silicates taking subordinate rank. In some instances all the acid radicals mentioned above occur in a single slag, and only in a few is but one of them present. Of the slag-making constituents in ores silica is the most widely disseminated, therefore it is advisable to begin the systematic study of the subject with compounds of that acid, giving consideration to the remaining substances as in effect replacing the original silica, appearing as phosphates, titanates, and so on.

Metallurgists have adopted a classification of silicates, both natural and artificial, based on the relative proportions of basic and acid oxygen contained in the compound. In the molecule of a mineral, such, for example, as wollastonite, the native silicate of lime, the basic oxygen, being that contained in the lime, amounts to one atom; the acid oxygen, being that contained in the silica, amounts to two atoms; hence the substance is termed a bi-silicate. Fayalite, the native silicate of iron, which has two atoms of basic to two of acid oxygen, is termed a singulo-silicate. The chemist, looking only at the molecular constitution of things, considers both as mono- or proto-silicates. In the metallurgical classification, sub-silicates contain two of basic to one of acid oxygen; singulo-silicates, one of basic to one of acid oxygen; bi-silicates, one of basic to two of acid oxygen; tri-silicates, one of basic to three of acid oxygen; quadri-silicates, one of basic to four of acid oxygen; and sesqui-silicates, two of basic to three of acid oxygen. It is considered that substances which crystallize are assuredly made up of acid and base in proportions that conform to one or

other of the above degrees, and not of mixtures of two or more. The phenomenon of crystallization is exhibited most conspicuously by the middle members of the list, being confined mainly to the singulo- and bi-silicates, neither the extremely acid nor the extremely basic compounds being found in nature; and we may remark in the artificial production of silicates a tendency on the part of acids and bases to unite in certain prescribed proportions when suitable conditions exist.

The classification and discussion of slags are often attempted from the same standpoint, that is, the oxygen of the acid constituent or constituents is compared with that of all the basic ones, as if to ascertain the fact of the silicate degree of the slag considered as a whole. Thus we hear of bi-silicate slags or tri-silicate slags, by which is meant the relative acidity of the whole compound, or the consideration of the compound as a class analogous to simple silicates. Little or no light is cast upon the subject of slag constitution by this method, and it is rare indeed that an analysis can be found that will yield results closely approximating any recognized degree of acidity. Even in the case of slags that are devoid of alumina, a substance that more than any other disturbs our calculations, it is common to find analyses indicating that the ratio of basic oxygen to acid oxygen may be as 9:10, as 7:11, or as 4:3, and so on, but rarely as 1:2, or as 2:3, which would conform to the conventional silicate types. An analysis, for example, may show basic oxygen as 11:10 acid, and this will be stretched to prove that the slag is a singulo-silicate. This is merely a mental exercise with no true relation to the facts, and without useful influence on metallurgical improvement. The reasons are, in the first place, that the analyses on which such calculations are commonly based are too lacking in exactness to permit of close discrimination; second, that the functions of several of the ordinary constituents of slag are not well enough understood; and finally, that the different bases do not often combine with the acid to form compounds of the same acidity in any given slag. Accordingly, silicates of different degrees of acidity may co-exist in the same slag. We may deduce from an analysis, for instance, that a certain slag should be classed as a sesqui-silicate, because its ratio of acid to basic oxygen is as 1.5:1, but it is more likely to be made up of a portion of bi-silicate mixed with a portion of singulo-silicate. Under conditions that will allow the different constituents to group themselves according to their preferences, as in the pyritic furnace, singulo-silicate of iron is formed, and bi-silicate of lime. This may be inferred from what seems to be fact, namely, that all the other heavy metals, whose action in several re-

spects is analogous to that of iron, will likewise form singulo-silicates under similar circumstances; and that the other alkaline earths, such as magnesia and baryta, will form bi-silicates under the same circumstances. Most pyritic slags, at least those containing a notable quantity of lime, together with ferrous oxide, would be classed as sesqui-silicate slags when the analysis is exact enough to enable any reasonable conclusion to be drawn; but, as a matter of fact, they are made up, as observation shows, of a mixture of singulo- and bi-silicates. It should be borne in mind, therefore, that the usual designation of slags by their degree of acidity is purely conventional, and that notions of their internal constitution, when based upon such calculations, are untrustworthy. The subject, for reasons that have already been suggested, is a difficult one, but it is made easier as more reliable analytical data become available.

On the introduction of pyritic smelting a better inkling was obtained as to the composition of slags, considered with regard to the different silicates contained in them. Their ultimate composition was fairly well known before, but not the way in which the acids and bases were grouped, nor is this thoroughly known now. The behavior of several components has eluded observation and test. In the pyritic furnace an ample amount of iron in the form of sulphides is always at hand, and it can make its escape either in the form of matte or of slag. Unsaturated silica, meeting the fused sulphide, decomposes it, giving rise to the singulo-silicate of iron, which is the main ingredient of such slags, and is sometimes almost the sole one. By comparison of many analyses of pyritic slags the conclusion that seems necessitated is that the silicate molecule contains two atoms of ferrous oxide in combination with one atom of silica. With this we have made a notable advance in slag interpretation, especially as other facts point in the same direction. Given a pyritic slag containing only ferrous oxide and lime as bases, the degree of acidity of the lime silicate is easily ascertained. This proves to be the bi-silicate, in which one molecule of lime is combined with one of silica.

With these two facts in mind we advance to the consideration of slags resulting from other processes, some of which follow the same law. A good deal of difficulty is found, however, in some particulars. On undertaking to compute from the analytical data the rational composition of a slag, that is to say, the proportional weight of the silicates present, it is ordinarily found that there is either an excess or a deficiency in the ingredients. Thus, there may be found two or three units showing more silica present than would correspond with a singulo-silicate of some particular base, whereas it would fall, perhaps, six or eight units short of being enough to form a bi-silicate, or the ferrous iron, the lime, or the magnesia, or something else may be in excess. It is rare indeed to find the elements existing in the precise proportion necessary to form normal, or what might be called 'standard', silicates, which must conform to the law of multiple proportion. What explanation can be advanced to meet the case? The impossibility of attain-

ing mathematically exact results by any chemical method is well understood, for the analyses of slags and even of the great bulk of mineral analyses are not much better than tolerable approximations to the truth. Hampe, in 1870, did not detect the magnetic oxide of iron in his ferruginous lead slag, although subsequent investigations have shown it to be almost universally present and uncombined. Among the analyses collected by Dana to show the composition of natural minerals, scarcely one conforms exactly to the chemical standard, that is, to the constitution as indicated by chemical principles. It would appear then that native minerals as well as slags may fail to conform to strict theory, and instead of being examples of perfectly constituted silicates, phosphates, and the like, they are mixtures of normal substances, or else they are heterogeneous compounds in which there is no definite ratio between acid and base. It is natural to look upon slags therefore as containing a portion of standard compounds of recognized basicity mixed with substances in which the principle of chemical proportion does not exist. It has caused great annoyance to scientific metallurgists that they have never been able to detect the precise manner and rate of combination governing slag formation, but from a practical point of view it matters little. No practical results flow from the slight excesses or deficiencies in either base or acid, for, so long as a mineral is fusible, it serves all the purposes of a favorable ore-constituent in the charge. What is known about slags is almost entirely empirical and the working limits of furnace slags are well known.

Aside from the considerations named above, the unforeseen and unknown activities supposed to reign at higher furnace temperatures have always furnished a potent, if imaginary, obstacle to the complete understanding of the modes of combination. Chief of all the factors is the remarkable solvent power of molten slags, enabling them not only to dissolve and mingle in an apparently homogeneous fluid, but also to absorb other bodies of the most unlike kinds, regardless almost of their differing constitution and specific gravity. This extraordinary solvent power, with the resultant miscibility so annoying to the investigations of the chemist and the physicist, is the tendency that, more than any other feature, makes smelting possible. If the silicates and other compounds in slags could be formed only on the plan of definite proportions, whereby the inevitable excesses of one or another component could not be taken care of, we could not imagine successful smelting to be carried on at all. To illustrate this point, suppose, for example, that there is a fused portion of lime silicate in which the proportions of the two ingredients are as their atomic weights, that is, as 56 of lime to 60 of silica, thus forming the bi-silicate; if to this a little lime or silica be added, a new mixture or compound will be formed, the previous ratio of base to acid thereby being disturbed, but the mixture will remain as fusible as before if the addition be not too great, and the resulting slag will not be changed in its apparent physical condition. The addition of silica to an amount less than 60 parts produces

the tri-silicate, but any intermediate quantity will be absorbed as well, although the analysis of the resultant slag will conform neither to the constitution of a bi-silicate nor a tri-silicate. The question under consideration is the seemingly impractical one as to the form of combination of the added substance. Are there intermediate silicates other than those that appear in nature and those that are discussed in chemical textbooks? Innumerable fusible mixtures are found, regarding which nothing is known except that they are detected in the analysis of slags. There are two aspects in which these and other salts occurring in slags may be viewed: first, they may be regarded as silicates formed at the furnace temperatures, existing as indefinite chemical compounds under conditions dissimilar from those explained by the laws of definite proportion; or, second, they may be considered as mixtures of definite silicates 'in solution', whatever that may be. It is probable that, just as glass is known to be a mixture of silicates existing as colloids, so the explanation of much that is found in slag-making must be sought in the principles of colloid chemistry. From a practical point of view it makes little difference which side prevails. It is enough for the practitioner to know that slags of widely differing content of one element or another are fusible and otherwise suited to his demands. While no one can deny a tendency on the part of the major constituents to group themselves in accordance with the law of chemical proportions, neither can he on the other hand fail to recognize the existence of important portions that seem to exist in defiance of such laws. In explaining this Ledebur and others have taught that slags are to be considered as solutions rather than as complete chemical compounds, a view that is applicable at least to a part of every industrially formed slag. Ledebur's opinion, however, does not answer the question; it only removes it a step further; for if there is anything to be gathered from the actual work of slag-making, it is the conception that, although the law of definite proportion prevails, under some conditions, giving rise to recognized classes of compounds, others are produced that are intermediate in composition. In pyritic smelting, and there only, the slag-formers have an opportunity to assert their preferences, and there we find evidence of a strong tendency to assume the simple relations demanded by chemical theory. In every other case the slag-formers are grouped by force, as it were, that is, they are compelled to combine by the powerful agency of heat. I have accumulated and studied a large number of slag-analyses from no less than 13 pyritic works, the great majority of which bear out my conclusions as to the mode of combination of the slag-constituents, after making reasonable allowance for the inaccuracies of analytical work. On the other hand, there are a few that seem to contain excesses or deficiencies of components, for which there is no present explanation, unless it may lie in the appearance of the silica as free quartz, a not uncommon thing in any form of smelting. In one plant under my charge I noticed the constant discharge of unmelted grains of quartz in a slag that, when separated

from them, was found to contain the proportions conformable to theory. The inclusion of such acid grains in the sample chosen for analysis would evidently produce inaccurate results. Another explanation is necessary for a different class of analyses, showing deficiencies of silica in pyritic slags. We may conjecture that this might have been caused by the presence of large amounts of magnetite, which is found in many slags, and is a frequent product of pyritic work. When estimating silica the smelter-chemist is apt to take too much for granted. He often dispenses with a fusion when it is needed for accurate work, and after weighing the silica he may neglect to test it for certain impurities that experience teaches are often present. Whole series of analyses have proved to be unreliable through disregard of simple precautions: small residues of silver, sulphate of lead, and sulphate of baryta, vitiate many an otherwise unexceptional estimation of silica, and it may be that some of the excesses of that substance in slag-reports are due to this cause. We need not go so far as some in claiming that the temperature is such a controlling factor that different silicates are formed at different temperatures. There is no proof of this, and the doctrine that in pyritic slags the iron exists as the singulo-silicate, while the lime and magnesia are present as bi-silicate, is founded on the chemical composition of the slag and not upon any assumption as to their temperatures of formation. The remark of a distinguished metallurgist that "the pyritic furnace chooses its own slag" was not a happy one, in that it seems to set at naught the influence of chemical laws. It would have been more exact to have said that the silica in the pyritic charge chooses its own partners, because it is only in this furnace, and in the copper converter, that it has the unhampered opportunity to attract in chemical proportion the constituents with which it would ally itself.

RUST-PREVENTION for small machine parts may be accomplished by applying iron phosphates to the iron or steel surface. After thorough cleaning, the articles are immersed in a bath containing ferric and ferrous phosphates, with a little manganese di-oxide, and, at the temperature of boiling water, they are left until hydrogen is no longer given off. The articles are then air-dried, when they may be treated with mineral oil, or painted, japanned, or otherwise finished. As the phosphate surface is attached chemically to the metal, no rust forms even in cracks in the paint.

A NEW HIGH-SPEED ALLOY STEEL, containing a high percentage of cobalt, has been invented. According to a patent (U. S. 1,233,118), which James H. Parker, of Reading, Pa., and B. H. DeLong, of Springmount, Pa., have obtained and assigned to the Carpenter Steel Co. of Reading, the new alloy contains 30% cobalt, besides 2% vanadium, 3.5% chromium, and 12% tungsten. The carbon content is 0.35%. While the patent covers a range of composition, the foregoing is stated to have given satisfactory results.—'The Iron Age.'

Construction of Slime-Dams

By JAMES E. THOMAS and E. A. OSTERLOH

*The type of construction for reservoirs that would give the greatest security would be that in which the retaining walls were built of dry material to the ultimate height required before putting the dam into commission, such walls being of the usual trapezoidal section, with the base proportioned to the load. As slime-dams, however, in the majority of cases have to be built of the slime itself, the most that can be done is to endeavor to make the outside walls of suitable thickness, using the coarser slime particles, and avoiding an excess of moisture. The site selected for the dam having been surveyed, a trench should be dug at least three feet wide by one and a half deep along the line which the toe of the outside wall is to follow. The object of this trench is to serve as a preliminary channel for conducting the slime-pulp and also, in some measure, to key the walls to the ground. The earth from this excavation should be thrown to the outer side. The pulp from the tailing-discharge pipe should be led along the trench in one direction, that is, either to the right or left of the pipe, which should be at right angles to the line of the trench until it will no longer flow. It should then be led in the opposite direction, and the partly dried slime from the first portion shoveled out and packed to form a channel at least 21 ft. wide, the lower outside edge of the wall thus formed coinciding with the outside line of the trench.

When the slime in the dam has reached a height of about two feet above ground-level L-shaped launders should be installed at suitable places to drain the excess of moisture from the surface. These launders should have a section of approximately 2 ft. 6 in. by 11½ in. inside, and arranged so that slats 2 by 1½ in. can be dropped into guides in the vertical portion facing the middle of the dam. The guides should be supported at intervals of 12 in. by horizontal struts nailed inside the launder. It is now possible to allow the pulp to flow from any part of the surrounding channels to the interior of the dam. The following system of control has been found to give satisfactory results: The pulp is allowed to flow along one channel to the other side of the dam farthest from the inflow, and is there led through the inner wall by means of short lengths of pipe to the interior of the dam. When the lower end of the channel becomes choked another opening is made nearer the inflow, and so on until the whole channel is full. The same procedure is then followed with the other channel. Meanwhile, the slime in the first channel is dug out and packed on the existing walls. As the outer walls rise they are stepped back about six inches every two feet in height and trimmed to form an angle of 50° with the horizontal. The stepping renders any portion of the walls easily accessible for inspection and repair. Make the walls straight, with the corners well rounded. This

ensures that the walls will receive thorough inspection, and it enables any tendency to bulge to be quickly detected, so that precautions can be taken to prevent the walls giving way. This may be effected by isolating the suspected portion from the rest of the dam, making a temporary channel farther in, while the repair is in progress, by making a new channel some distance from the one abandoned. In bad cases a new supplementary outer wall must be built from heavy slime. The flow into the dam from main channels should be so regulated that any superfluous water or solution is kept well away from the walls and not allowed to remain too long at any one drainage launder.

In order effectively to conduct repairs we recommend that two adjoining dams be used alternately and kept nearly at the same level. Then, if extensive repair to one dam be required, no inconvenience will be experienced in disposing of the tailing that is arriving from the slime-plant, and ample time may be given. The solution or water from the drainage launders should be led to a special dam, adjoining the slime-plant, from which it may be returned to the slime-treatment circuit with a minimum expenditure of pipe and power-lines. For this purpose a trench of slime may be built outside at the base of the main walls, so that the solution will gravitate toward the slime-plant. This trench to some extent acts as an anchor for the toe of the outer walls. It will be evident that, as the vertical portion of the drainage launders and the outer walls approach one another, arrangements must be made to carry the launders farther toward the middle of the dam. This may be done by attaching another L-shaped launder to the top of the first, and so on, as the level of the slime in the dam rises. We find that a length of 12 ft. is most convenient for the vertical launder, with 24 ft. for the horizontal portion. If the inner walls of the main channels are kept within a foot or so of the vertical launders, the fitting of slats becomes an easy matter. It also enables close observation to be kept on the interior of the launder for any broken slats.

When starting again to build up a dam which has not been used for some time, it will probably be found that holes have formed, causing leaks at unexpected places in the outer walls. It is useless to try to stop such leaks from the outside, but it can be done from the inside by allowing nothing but slime to pour into the hole, meanwhile working a shovel at the inlet to cause the sides to collapse and to choke the hole lower down. It has been noticed that walls built in the manner described show comparatively little erosion even after the heaviest rains. This is partly because the fine sand in the heavy slime acts as a binder. Care must be taken, however, that the amount of sand present is not excessive or the walls will crumble away when dry. Slime with 1.5 to 2% fine sand yields a heavy portion suitable to making the outer walls. A moisture-ratio of 1 to 1 is sufficient when discharging slime-pulp. Two dams with a total circumference of 6000 to 7000 yd., built in the manner described, will be found sufficient to receive the tailing from a plant capable of treating 50,000 tons per month.

*Abstract: Chem., Met. & Min. Soc. of S. Afr.

Notes From the Front

By Capt. R. HODDER-WILLIAMS

*There are two advantages in speaking first: one is that, when it is all over, you can enjoy your pipe, and the other is it gives me a chance to get off my only story. This story is told of the very early days of the War, when Kitchener's original 100,000 were training hard in England, and they were getting all sorts of funny people into the ranks. In one battalion of a London regiment, there happened to be a large number of Stock Exchange men, men of about 30 years. These fellows, of course, didn't know anything about army discipline and eared less, and the first few days they were having a great time, but they were pulled up with rather a rude shock when they received, as new company commander, a boy of 18 who had been given a commission when the War broke out. He had rushed into France, been wounded at the Marne, returned to England, and very shortly was back training one of these new battalions. He had gone out as a second lieutenant, but as he had had some war experience, they made him a captain, and this boy proceeded to give them general hell all around, and they didn't altogether like it. So, after a time they hit upon a phrase which they took from a well-known book, well known even to stock exchange men; the phrase was "a little child shall lead them," and this phrase went up and down the ranks all day long. They sang it as they marched, and passed it up and down the line. "a little child shall lead them," and the officer took no notice of it at all. In the afternoon, on parade, again this refrain went up and down the line, "and a little child shall lead them." Still the officer took no notice. It went on until the end of the day. At five o'clock he called them to attention and announced, "Training for tomorrow; there will be a route march; it will be a very long route march; we shall go 26 miles; we shall go in full marching order and we shall carry rifles; we shall carry ammunition; we shall carry everything we shall need; it is going to be very hot and we are going 26 miles; and a little child shall lead them—on a horse."

You will perhaps be a little surprised to know that I feel as one fallen among thieves. The infantry-man regards the mining engineer with all the loathing that is to be expected of him, considering their relative duties in the front line. Of course all engineers—sappers, as we call them in the British Army—are a confounded nuisance to the infantry-men anyway. They come and tell us what to do and then leave us to do it; but the worst of all is the mining engineer; he has become a tunneling company out there, and if there is anything worse than a tunneling company, I want to see it.

The tunneling company works underground, but something has to come out of the tunnel. Do the tunneling companies take their earth away? Oh, no! That, according to the tunneling companies, is exactly what the infantry are for. The earth comes out in sand bags; it is heavy and wet, and you may leave it there, but if you do, one of several things will happen; in the first place, it will stay there because it can't move itself; in the second place, it is sure to block up the trench because the tunneling company waits on no man; in the third place, the sand bags will come over the top of the parapet and the accumulation will be duly noticed by our friends on the other side, and having noticed it, they will duly proceed to demolish the sand bags—all very nice for the tunneling company, 40 or 50 ft. underground, but pretty rotten for the infantry; so you see, of two evils the lesser is to take their beastly sand bags and clear them away, which takes a long time and is hard work; so I hate all mining engineers.

I wish to say a few words a little more seriously. There is only one thing that counts in the soldier's life in this War, as in any other, and that is discipline. There is a lot of talk about not needing the German discipline. That is absolute buncombe; you must have just as good discipline as the Germans have before you can hope to win the War. There are various ways of getting discipline; we are after it in a different way from theirs. So far as possible, we try to make men understand the whole principle of self-discipline, but do not, for a moment, think you can succeed in this War with less discipline because you come from North America. The only thing that will happen to you, if you have less discipline, is that you will get killed. The only way you can possibly hope to win the War is to have discipline at least as good as the Germans. I have a perfectly good reason to dislike the Germans, but they have a superb discipline, and that discipline extends far beyond the army. The very fact that all this fuss was made over the first real strike they had a few weeks ago, and the speed at which it was put down, is sufficient proof that the German people are disciplined.

It is extraordinarily common over here to hear people say, "We are all in it, this is a people's war," etc. It rather reminds you of Robert Louis Stevenson's phrase, "A man should not live on bread alone, but principally on catch-words." A good many of us are inclined to live on catch-words. Do we realize just what being 'a people's war' means? It means that the American people have got to discipline themselves and not leave all the discipline to the soldiers. You cannot begin to win this War until you have all America fighting all Ger-

*A speech made at the War Smoker of the A. I. M. E., New York, on February 19, 1918.

many. Don't ask American soldiers and American sailors to fight the German people; they can't do it. We will look after the German army, but it is up to you to help look after the German people. The German people, whether willingly or not, are mobilized against us; are the American people mobilized against the German? The vital importance of discipline everywhere I think is beginning to be felt, but rather slowly. Of course you can imagine that labor strikes make a soldier pretty mad; when soldiers go on strike, we get shot for it. There is lack of discipline in Canada as well as in the United States and in other quarters, and in other walks of life and in other professions besides labor; and the question is whether the people are going to settle down to the disciplining of themselves, without which the winning of the War is absolutely hopeless.

What is discipline, gentlemen? It is something the outward and visible sign of which may be saluting, and a smart uniform, and obeying orders, and so on; but its inward grace, more important than that, enables us to stick at things whether they are pleasure or not, and not to count the cost. It may seem easy, in the excitement of battle, to forget the cost, but it is not easy, because you see what is going on. The time comes to almost everybody as it came to me on the 15th of September, 1916, to realize, if you are a leader, that all you have to do, all that you have been doing through the gruelling of the last two or three years, is going to depend absolutely on the discipline of those men behind you. As we went forward, everybody was having a great time; suddenly we were absolutely at the mercy of the German machine-guns, and there was nothing to do but to rush them. Can you imagine the feelings of a man as he goes ahead to lead his men forward, who knows without ever turning his head, without ever hearing or seeing a man, that those men are right behind him, trying to get in front of him all the time, to get at that machine gun? That is discipline. We got the machine-gun, and the price we paid was perfectly terrible, but it is being paid all the time. If I have any message to give you gentlemen in a profession in which I imagine discipline counts a great deal, it is just to ask you to spread the gospel of discipline outside the Army.

ZIRCONIUM in sand may be determined as follows: Fuse the sample with NaOH and Na_2O_2 and remove the SiO_2 and the metals that come down with H_2S , in the usual manner. Faintly acidulate the solution with H_2SO_4 and add H_2O_2 until there is no further change of color, after which make up the solution to a definite volume and remove an aliquot part representing about 0.1 gm. ZrO_2 . Add to this portion 10 cc. conc. H_2SO_4 , and also some H_2O_2 ; then dilute until the H_2SO_4 is about 10%. Precipitate the zirconium by adding 10% sol. of Na_2HPO_4 . Wash the precipitate with dilute H_2SO_4 by decantation as long as any color can be removed, and then work up with the least necessary amount of water in a beaker and dissolve in 25-30 cc. boiling concentrated H_2SO_4 . Pour this solution into 300 cc. of water; add H_2O_2 and re-precipitate with Na_2HPO_4 . As it is

impossible to wash this precipitate completely, it must finally be dried and fused with NaOH. Digest the fused mass with water, acidulate with HCl, filter, wash, dry, ignite, and weigh as ZrO_2 . Thorium and titanium are completely separated by this procedure.—'Chem. Abstr.'

Tests for Molybdenum

In a circular on molybdenum, issued by the Colorado School of Mines, the following tests are summarized by Harry J. Wolf:

1. Treat a small quantity of finely powdered ore with 5 cc. of concentrated nitric acid. Evaporate to dryness. Treat the residue with 0.5 cc. of concentrated sulphuric acid. Again evaporate to dryness. If molybdenum is present an ultramarine blue color develops in the residue on standing from 2 to 12 hours.

2. Fuse the finely powdered ore with equal parts of sodium and potassium carbonates and a small amount of potassium nitrate. Powder the fusion and dissolve with hot water, and filter. Acidify the filtrate with hydrochloric acid, boil, and add potassium or ammonium thiocyanate, and a small piece of metallic zinc. If molybdenum is present a bright cherry-red color rapidly develops, which disappears on standing in the presence of the zinc. If hydrogen peroxide is added to the solution immediately after the cherry-red color has developed, the color disappears, returning as soon as the peroxide has been reduced. If the amount of molybdenum present is known to be small, this test may be more delicate if, immediately after the thiocyanate and zinc have been added to the acidified filtrate from the leached carbonate fusion, the solution be shaken with a small volume of ether. The color will be intensified as a golden brown in the ether ring that forms at the top of the liquid on standing.

3. Molybdenite gives off sulphurous fumes when heated in a closed tube, and a pale-yellow sublimate of molybdenum trioxide is formed. The mineral is infusible before the blowpipe, and imparts a yellowish-green color to the flame. On charcoal it gives sulphur fumes and a slight sublimate, yellow while hot and white when cold, and deep blue when touched with the reducing flame. It is soluble in strong nitric acid, leaving a white or grayish residue. It gives a blue solution with sulphuric acid.

4. Wulfenite decrepitates and fuses below 2 before the blowpipe; yields a metallic lead when heated on charcoal with soda; with salt of phosphorous it gives a yellowish-green glass in the oxidizing flame which becomes dark green in the reducing flame. With borax in the oxidizing flame it gives a colorless glass, which, in the reducing flame, becomes opaque black or dirty green. Strong hydrochloric acid gives a green solution which, when diluted and stirred with tin, becomes deep blue and finally brown. On evaporation with hydrochloric acid, if the residue is moistened with water and zinc is added, a deep blue solution results, which persists after dilution.

Mining in Colorado

By ARTHUR J. HOSKIN

'High-grading' has been before the courts again. The Supreme Court of Colorado played an April Fool joke on mine-operators in general. The Portland Gold Mining Co. had secured a ruling from the District Court at Cripple Creek to the effect that injunctions could be issued to prevent the purchase by assayers of high-grade ore, precipitate, amalgam, and bullion. Custom assayers were offended by the ruling and carried the case to the Supreme Court, which held that it would be as difficult to prove a violation of an injunction as to discover theft of ore and therefore reversed the decision of the lower court.

Faith in the San Juan region is shown by the various efforts to revive abandoned properties. The Mammoth tunnel, the portal of which is on Cement creek, near Silverton, was driven, years ago, more than 2000 ft. to intersect the Henrietta vein, and was abandoned after the depreciation of silver. It is proposed to re-open and complete this bore. Another tunnel, the Hammond or Treasury, piercing Red mountain from another side, is to be operated now as the Ouray tunnel by Col. Thomas Crawford. The objective is the Tomboy vein, which it will cut at a depth of 1000 ft. lower than any existing workings.

Everybody in the San Juan rejoices over the success attending the acquisition of the Sunnyside properties by the United States Smelting, Refining & Mining Exploration Co. This subsidiary, the Sunnyside Mining & Milling Co., is reported to have expended nearly one million dollars in re-modeling and newly equipping the mine and mill. The mine has been worked almost continuously since 1875. The flow-sheet of the mill now includes automatic scales, steel bins of 1000 tons capacity, automatic samplers, pan-conveyors, Marcy ball-mills, and Dorr classifiers. Within a month the Camp Bird tunnel should reach its main vein. During March the heading advanced 515 ft. Plans call for drifts along the vein and raises to connect with old workings 500 ft. above. The bore has cut a dozen mineralized veins, thus proving, better than ever before, the true character of the San Juan fissures; the lowering of water levels in various shafts in this district demonstrates the porosity of the ground.

Gilpin county is distressingly quiet—at least that is the impression one obtains from a hasty trip. There is activity underground that is not manifest on the surface for the reason that some operations are conducted through tunnels with portals at Idaho Springs in the adjoining county of Clear Creek. At the same time this famous old district is not making the showing it should. An analysis of local conditions shows that Gilpin is in a state of somnolence from which it cannot emerge until

modern ideas of mining, backed by capital and engineering talent, are introduced. It is inconceivable that the district is exhausted. Criticism may well be aimed at the wasteful methods of mining—and especially of milling—followed during the palmy days of this county, but the time has come when the mines must be worked at depth for low-grade sulphide ores, and this means radical changes in the dressing of ores. Without working deeper in the old mines, millions of tons of low-grade ore might be salvaged if the district had modern mills. Why is flotation not introduced? Here is a field open to wide-awake investors. There is a most interesting history associated with Black Hawk and Central City. It was

PART OF NORTHERN COLORADO.

here that the first gold ore in place was found in Colorado.

Although little is heard about tungsten mining in Boulder county just now, the fact remains that there is much activity in this kind of mining. The Conger and Wolf Tongue properties continue to produce good tonnages. The Long Chance mill is treating tungsten ore from its own mine. Warren Bleeker and R. D. George are prominent in the promotion of a company that has taken over the Lucky Two and other tungsten mines, the ores from which will be concentrated and reduced in a complete plant at Boulder. Another tungsten company is headed by George Bland, son of 'Silver Dick' Bland, running partner with one William Jennings Bryan in 1900. Instead of the industry lagging, as some have imagined, Boulder county probably produces one half the nation's tungsten.

REVIEW OF MINING

NEW YORK

Financial.—John Fritz Medal and New York Water-Supply.

The week has ended with a marked appreciation in the average of quotations. War issues of the United States and Allies have uniformly risen, and the majority of security prices have advanced. This has been largely due to the optimistic interpretation of war news, and the gradual diminution of German successes of the Western front. The shares for the most part have been in strong hands, a fact evidenced by the absence of any trace of panic since the German offensive started. The War situation absolutely rules the market. With the promise of dollar silver there was practically no change in the quotations for shares of prominent producers. The third Liberty Loan campaign claims first attention, and the drive is being carried on with a vigor and thoroughness that should ensure success. A satisfactory feature of the returns so far is the increase in the number of subscribers. With regard to the amount, New York is lagging behind with only about 45% of the minimum subscribed. This has been made a reason for a re-doubling of effort on all sides, although the actual amount compares favorably with the sum raised during the corresponding period when subscriptions were being solicited for the second loan. It is thought that several influential prospective buyers are holding back in order to see to what extent it will be necessary for them to subscribe in order to make the loan a success. It is also felt that large subscriptions in the early stages of the campaign would tend to create a feeling of over-confidence among those who were undecided, and who might think that success was certain without their participation. Although New York city has led in previous campaigns, this has been due in a large measure to the fact that the great manufacturing companies have their offices in the city, and swell the local receipts by subscribing here. These corporations will be obliged to meet the year's excess-profit taxes within a couple of months, and this fact may have resulted in a reticence to the new loan to the extent previously possible. It is interesting to note that there has been no slackening in the sales of thrift and war-saving stamps since the loan drive commenced, but rather the reverse. Total sales of stamps since the scheme was inaugurated last December have amounted to over \$160,000,000, daily receipts from this source showing a regular and gratifying increase.

The presentation of the John Fritz gold medal to J. Waldo Smith in recognition of his achievement, as chief engineer of the Board of Water Supply of New York city, in the construction of the Catskill aqueduct, was the feature of interest at a recent meeting held at the Engineering Societies building. Mr. Smith is also a director of the Old Dominion Co. and the Old Dominion Copper Mining & Smelting Co. The medal is awarded annually for especial achievement in science, architecture, or engineering, the recipient being chosen by a special committee of the American Institute of Mining Engineers, American Society of Civil Engineers, American Institute of Electrical Engineers, and American Society of Mechanical Engineers. The Catskill water-scheme ranks high in engineering achievement. The need for an ample reserve of water for this city is patent when it is remembered that the population is increasing at the rate

of 125,000 annually. The scheme provided for the collection from watersheds delivering to several creeks in the Catskill mountains, with an approximate delivery of 500,000,000 gal. per day. In addition to the necessary reservoirs, the scheme comprised the building of 92 miles of aqueduct to the city's boundaries, for which contracts were let totalling \$76,000,000. Four types of conduits were constructed. What is known as the 'cut and cover' system was adopted for 55 miles. This consists of a horse-shoe shaped tunnel of an interior measurement 17 ft. high by 17½ ft. wide. This was of concrete construction, and was buried underneath an earth embankment when completed. Grade tunnels were driven where the contour of the ground suggested it. Twenty-four of these were constructed, covering a total length of 14 miles. These tunnels were also horse-shoe shaped, and were concrete lined. Pressure tunnels were necessary underneath rivers and valleys. Seven of these were constructed, covering a total length of 17 miles. This construction was adopted in the case where the ground was hard enough to permit satisfactory tunneling. The conduits in this case have a diameter of 14 ft., and are circular in cross-section. A vertical shaft connects with the entrance and exit of the pressure tunnel. In those cases where pressure tunneling was impracticable steel piping was used, and 14 miles of this was laid. The pipe was of riveted steel-plate varying in thickness from ⅝ to ¾ in. This was afterward lined with cement mortar. An exceedingly difficult problem was encountered in the work of connecting the boroughs of Brooklyn and Richmond. In this case a flexible jointed cast-iron pipe was used, which was laid in the mud below the neck of water in New York harbor, known as the 'narrows.' Diving work was restricted to a few hours twice a day, as the tide at other times was too swift to permit of any submarine observation. An interesting feature of the work resulted from the need for ample aeration of the water at the reservoirs in order to break up the minute organisms found to exist. For this purpose a special type of rifled nozzle was used, and natural aeration insured by effective spraying. New York water is especially soft and palatable.

ELY, NEVADA

Copper, Manganese, Lead, and Oil-Shale.

The Nevada Consolidated company's works are running smoothly these days, with an average production of 15,000 tons daily. Of this quantity 3500 tons is from the Ruth mine, the remainder from steam-shovel operations. The new hoist, with a capacity of 5000 tons in 16 hours, is in operation at the Ruth mine. Some time since the painters at the smelter demanded 50c. additional per day (now receiving \$5.25) or they would walk out. The company not being anxious to paint during cold stormy weather let them walk out, paying them off. The company has finished the 100 dwellings started last fall at the smelter and is now erecting 25 more. The rentals received will not average 6% on the investment, but a more permanent and better class of laborers is secured thereby.

The Consolidated Coppermines Co. is working both sections of its mill. Pumps are in operation on the 1200-ft. level of the Giroux shaft, and work is being carried on from the 1100 and 1200-ft. levels. It is reported that the com-

ppany will sink a new shaft between the old Alpha—which is caved—and the Morris shaft. This is much needed, as at present there is no means of egress in case of accident to the Giroux.

The Nevada United company (old Ward), 18 miles south of Ely, is shipping 40 tons daily of lead-silver-iron ore. A large tonnage is said to be available.

Holmquist is shipping 25 to 30 tons of manganese daily from his property 7 miles south-east of this place. The ore contains 43% Mn. The owner had a good offer for the property last week. Holmquist, leasing on the Keystone claim of Nevada Consolidated, shipped one car last week, quarried from the surface.

A. B. Witcher, from an adjoining property, is shipping 15 tons daily.

Schmidt brothers (Italians), leasing on the Golden Fleece of the Coppermines company next to the Ely-Revenue, have shipped four cars of 45% manganese during the past month.

Shipments are being started from the Hamilton lead-silver district. Lessees during the past winter mined a considerable tonnage. Roads are now in fair order for moving ore. The old stage road north from Keystone to Hamilton will be repaired this season. It has the best grade, but has not been used in recent years. The Federal government will expend \$31,000; the State and White Pine county jointly an equal amount. The State Engineer has had this route surveyed during the past month.

Many locations of oil-shale have been made in recent months about 35 miles west of Ely and a few miles east of Hamilton. Local people have organized a company with Arthur Smith as president. E. E. Vanderhoef, superintendent of steam-shovel operations of the Nevada Consolidated, is to be general manager and will have charge of drilling for oil. Sufficient money has been raised for the services of a petroleum engineer to make a thorough examination as the first move.

PLATTEVILLE, WISCONSIN

Summary of Activities of Wisconsin Zinc Co.

The Wisconsin Zinc Co., incorporated under the laws of Maine with a capital of \$1,000,000, is at present extensively engaged in zinc mining in this field under the able management of A. W. Plumb, formerly of Denver, Colorado. The company is one of the largest zinc-ore producers. It also operates one of the Skinner zinc-ore separators, and an industrial railway that connects its several properties with the main line of the Galena division of the Chicago & North-western railroad. Three mines in the New Diggings district—the C. A. T., Champion, and Longhorn—are producing from 800 to 1000 tons of zinc concentrate per week. A new mine recently developed and equipped is on the Copeland estate, in the Shullsburg district. It made its initial ore deliveries during the third week of March. One of the most consistent producers of the field, from 1912-1918—the Winskill—also at Shullsburg, was exhausted and abandoned on March 16. The equipment will be dismantled and moved. Drills are engaged by the company on various tracts in the Benton, Hazel Green, Shullsburg, Galena, and New Diggings districts. Several prospects are ready for development. Ore from mines to roasting plant, thence to rail, necessitated motor and steam-tractor trains until recently, when the Wisconsin Zinc, Vinegar Hill Zinc, and New Jersey Zinc companies combined to construct and operate at their own expense an industrial spur. Officials declare that this is of great benefit to all. Sales of dressed ore are made in open market to the highest bidder, although the Wisconsin Zinc Co. is a subsidiary of the American Zinc, Lead & Smelting Co., and is in this manner affiliated with the American Zinc Co. smelters, at Hillsboro, Ill., to which point much of the finished ore finds its way. Heavy ship-

ments are made at intervals of pyrite saved as by-product in the separation of zinc ore. The pyrite carries 30 to 35% sulphur. The Skinner roasters were completed in 1916 at a cost of \$100,000. They are capable of treating 1000 tons of raw zinc concentrate weekly. From this is recovered 500 tons of 59 to 61% blende. Cleveland-Knowles and Dings separators are largely employed in this plant, also the McDougall furnace. Fifty men can operate the plant per 24 hours. A wet mill was erected during the summer of 1917 to wash out fine and slime. The Overstrom sludge-table is mostly used. The ordinary method of wet concentration employed in the Wisconsin field is regarded efficient enough to eliminate the necessity of saving the small amount of mineral lost in slime. The wet plant mentioned is now standing idle. Between 500 and 600 men are employed by the Wisconsin Zinc Co. Sociological conditions of the workers are given plenty of attention. Wages paid are good, and labor conditions within the past three months show improvement. Mill feed is handled on the can-contract system. Shovelers earn from \$3 to \$5 each per shift. Power is supplied the company by the Inter-State Light & Power Co. of Galena, Ill. It is steady and good. A telephone system connects the general manager's office with mine foremen underground. Your correspondent, after an interview, learned that no new mills will be erected this season on account of the present ore market. Dividends have been disbursed to June 1, 1917, on an annual basis of 8%. Quarterly payments amounted to \$20,000. Quick assets in the field are scheduled at over \$1,000,000.

TORONTO, ONTARIO

Coal, and Lignite Briquettes.—British-American Nickel Corporation.

The problem of providing against a shortage of fuel, in view of curtailment and possible entire cessation of supply from the United States, is receiving much attention. The necessity of speedy and energetic action has been impressed upon the public by a recent order of the Dominion Fuel Controller, limiting the supply to consumers to 70% of their normal requirements, and in all cases where hydro-electric power can be effectively substituted, the use of coal for power will be prohibited. Investigations of the Advisory Council for Scientific and Industrial Research having shown the feasibility of producing carbonized briquettes from the lignite of Saskatchewan, as a substitute for anthracite, the Canadian government, in co-operation with the Provincial governments of Saskatchewan and Alberta, has undertaken to establish and operate a briquetting plant in Saskatchewan capable of producing 30,000 tons of briquettes per annum. The cost of the plant, including expense of operation for a sufficient time to establish a practical process, is estimated at \$400,000. Of this, the Dominion government will furnish \$200,000, the Provinces interested the remainder. The Advisory Council finds that two tons of lignite will produce one ton of briquettes, approximating anthracite coal in heating value for domestic use, in addition to yielding by-products such as oil, pitch, ammonium sulphate, and gas. Meanwhile, some of the Alberta coal companies are endeavoring to obtain a market for their output in Ontario, though it is doubtful whether much relief can be expected from this source with the present high freight charges.

Sudbury.—The British-American Nickel Corporation is making good progress with construction of its smelter. About 650 men are engaged. The plan of establishing its refinery in the Sudbury district was abandoned some time ago, on account of the excessive cost of obtaining a supply of power. A site was recently secured at Deschenes, near Hull, on the Quebec side of the Ottawa river, and construction will be proceeded with immediately.

ALASKA

Anchorage.—The Government railroad is likely to be delayed considerably by present conditions. During the season of 1917 there were 6000 men employed, but for the coming season only half of that number are expected. According to W. C. Edes, chairman of the Alaskan Engineering Commission, during the last two seasons, there was practically completed the coastal sections of the line, along which transport conditions enabled work to be done at a number of points at the same time. In the future construction will go straight into the interior, extending the line at most from only two points. Assuming the usual Congressional appropriations become available, the Commission, which still has some doubts about its ability to secure even half the labor force it had a year ago, will centre its effort during the coming summer upon the completion of the main line from Seward to Anchorage, both of which are Pacific Ocean ports on the Alaskan southern seaboard, between which a rail gap of 17 miles now exists. Main railheads in addition will be pushed 40 or 50 miles toward the interior terminal, which is Fairbanks, opening the line approximately from mile 215 to mile 265, distance estimated from the ocean terminus at Seward northward. In Alaska, except in certain places and on certain types of work, the Commission has found that construction is only practical during the summer after May 15. The average scale of wages paid during 1917 would work around \$1500 per year, but it actually does not run a year for more than a part of the men, because of the seasonal character of the work. As a side issue to railroading, the Commission operates, on a small scale, coal mines at Matanuska, on a branch line 38 miles from the trunk, and is doing some port dredging at Anchorage, and building docks and coal bunkers at Anchorage and Seward. To date, \$23,870,000 has been spent upon the enterprise, out of a \$35,000,000 estimate for the total cost, which the Secretary of the Interior has raised to \$40,000,000, because of higher costs of labor and materials.

Juneau.—Alaska Gold Mines Co. made a profit of \$42,274, after paying interest but before depreciation, during 1917. In 1916 the profit was \$112,833. Alaska Castineau shows a deficit of \$792,789, compared with \$105,740 in the previous year. Last year, 2,240,346 tons of \$1.103 ore was milled, against 1,892,788 tons and \$1.193 in 1916.

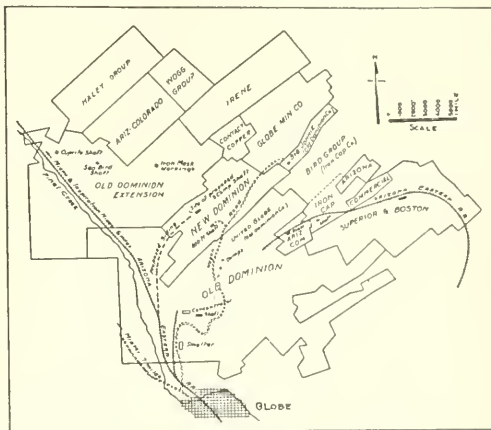

Kennecott.—It is reported that the Kennecott Copper Corporation is negotiating with the Mother Lode company for acquisition of the latter's property nearby.

ARIZONA

Christmas.—The Gila Copper Sulphide Co., having a mine here in Gila county, and another in Pinal county, is in the hands of a receiver, Allan Forbes of Boston. Company is said to have defaulted in payment of \$690,000 on mortgage bond that matured April 1. The mines at Christmas have been under bond to the A. S. & R. Co.

Globe.—The Superior & Boston Copper Co. in 1917 reports a revenue of \$383,541, of which \$340,198 was from ore sales. The year started with a balance of \$176,107, and ended with \$141,577. The superintendent, A. L. Graham,

states that 17,146 tons of ore was mined. Development, including sinking the McGaw shaft 145 ft. to the 1400-ft. level, totaled 2782 ft. A Nordberg 500-gal. pump was erected at 1200 ft., while another is being put in there also. These pumps will have a capacity of 2,000,000 gal. per 24 hours. The cost of pumping was reduced 20%. The labor situation affected operations considerably. New ore on the 1000 and 1400-ft. levels is very promising. Purchase of the Telfair claims adjoining was recommended by George King-

PROPERTY MAP OF GLOBE DISTRICT, ARIZONA.

don and W. X. Osborn. This was done, cash and shares being paid for the 200 acres.

The Moline-Arizona Copper Co. is working 21 claims one mile from the Old Dominion smelter. A shaft is down 415 ft., to be deepened to 800 or 1000 ft. Considerable development is contemplated. Walker & Sons, of Moline, Illinois, control this company, which has a capital of \$2,000,000. B. F. Baker is in charge at Globe.

Hill Top.—The Ajax Metal Mining Co., with an office at Denver, Colorado, and mines on Tail creek near Hill Top, is making regular shipments of copper, lead, and silver ore to El Paso. A recent lot of three cars returned 12% copper, 16% lead, and 14 oz. silver. Recent development opened a 5-ft. vein assaying 42% lead, 18% copper, and 24 oz. silver. Equipment includes a 75-hp. Otto gas engine. A 480-ft. Ingersoll-Drill compressor and five Clipper drills from Denver Rock Drill Co. are to be added.

Jerome.—The Verde Squaw is making good progress in its adit.

Jerome Superior's new machinery is at work, save the hoist.

Mammoth.—The Galiuro Molybdenum Co., operating the Childs mine in Pinal county, 11 miles from this place, is to order a mill costing \$10,000. Workings total 850 ft., 475 ft. said to be in ore assaying from 0.33 to 10% MoS₃. One

portion blocked out contains 4820 tons of 2% ore. Operating costs are estimated as \$11 per ton. W. R. Ramsdell is in charge.

Oatman.—Grading for crushing plant of Gold Road mines has been completed. This plant was purchased from Union Basin company. Rich gold-silver ore has been opened for 75 ft. during stoping, 35 ft. above 650-ft. level of the Gold Ore. The mill is treating 50 tons per day.

Big Jim Consolidated is to develop its Blue Bird property at once.

The mill of the Secret Pass Gold Top Mining Co. is treating 15 to 20 tons per day. Sufficient ore is developed to keep the plant operating for two years.

Payson.—The Mazatzal Mining Co. is operating 16 miles west of this place. A recent report by company's engineer, R. J. H. Bradley, states that House No. 1 adit is in 1000 ft. A fault-vein was cut assaying \$4 silver per ton, also House No. 1 vein, 12 in. wide at depth of 200 ft., containing \$125 per ton in gold, silver, and copper. Further work proved the body to become poorer when widening to 36 in. House No. 2 vein was also cut, 18 in. wide, worth \$19 to \$35 per ton. It is proposed to sink a shaft from No. 1 adit to a depth of 500 ft., to cost \$75,000, including necessary plant, plus \$25,000 for other work. The company is considering buying motor-trucks to haul ore to the smelter, 88 miles distant.

Prescott.—Ore carrying 16% copper has been opened at depth of 68 ft. in Maiden brothers' property in the Thumb Buttes district.

Shaft of the Arizona Copper & Mining Co. is down nearly 500 feet.

Melver, Long, and other Mohave county men have taken over interests of the Kay Copper Co., in the Black canyon. Purchase price was stated as \$150,000. Anticipating immediate development, the town of Canyon is active.

Stoddard.—Employees of the Arizona Binghamton Copper Co.—105 in number—have subscribed \$20,000 to the third Liberty Loan.

Tucson.—University of Arizona Bulletin No. 81 is entitled 'How to Organize for Safety', by S. C. Dickinson. The subject covers 52 pages, and should be of value to mining companies who have or are contemplating organizing a safety department.

CALIFORNIA

Bishop.—Four mills are dressing tungsten ore in this district, while other companies are developing their properties.

Bollinas.—New mill of the Checto Mining Co. is working three shifts. Ore comes from No. 1 level, but as soon as an electric pump is installed the shaft is to be unwatered. A 3000-ft. flume has been built to carry tailing to a dam. An auto-truck hauls concentrate to the wharf here, also carrying employees back and forth to the mine, four miles away.

Dutch Flat.—W. A. Bliss has acquired the McGuire placers at Lowell Hill and is arranging to build a dam on Bear river. The gravel has been carefully prospected and carries considerable gold.

At the Wisconsin placer mine, W. S. MacDonald is operating with 14 men and extracting rich gravel. The property is a mile below Dutch Flat, and was formerly known as the J. L. Gould.

Folsom.—The Noble Electric Steel Co. is concentrating 60 tons of chrome ore daily near Negro hill.

Grass Valley.—A brief strike for increased wages at the North Star was ended on April 26 when the company granted an increase of 50c. per day, effective May 1.

Miners here will now receive a minimum of \$3.50. Other mines in the district gave a 25c. rise on the same day.

Ingot.—The Afterthought Copper Co. has 60 men in its mine and as many more in the mill. Only one unit of the flotation plant is working, dressing 150 tons of ore per day. The town is once more prosperous.

Keswick.—The Crescent Copper Co. has been granted permission by the State Corporation Commission to issue 6000 shares, par value \$1 per share, to certain persons in exchange for three separate groups of claims near Keswick. The company is also permitted to sell 25,000 shares at par for cash, so as to net 80% of the selling price. Money obtained from the sale of shares is to be used in the purchase of equipment and for development.

Murphys.—The Sheep Ranch gold mine near here is being sampled by a syndicate that has an option.

Nevada City.—The Birchville Consolidated Mines Co. has been granted permission by the State Corporation Commission to issue 125,000 shares of its common stock in exchange for mining properties in the Eureka mining district of Nevada county; also to sell 50,000 shares of its preferred stock at \$1 per share, so as to net not less than 80%.

Trinity Center.—On April 19 the Estabrook Gold Dredging Co.'s boat sank, the bow being in 26 ft. of water. The cause is not known yet. Buckets are of 7-cu. ft. capacity. The boat is an old one, and a new one is under construction.

COLORADO

The customary splitting limits as usually agreed upon in ore-buying contracts in Colorado are as follows, according to 'Metallurgical and Chemical Engineering':

Gold	0.02 of an ounce
Silver	0.50 of an ounce
Copper	0.50 per cent
Lead	0.50 per cent
Zinc	1.00 per cent
Iron	1.00 per cent
Insoluble	1.00 per cent
Sulphur	1.00 per cent

Boulder.—Victor is the newest tungsten centre of this county, 33 miles east of Nederland. The Wolf-Tongue owns a quarter of the area. In the Victor, Philadelphia, Rinn, and others considerable ore has been opened.

Fluorspar in large quantities has been extracted from mines in the Jamestown district of Boulder county. The fluorspar mill of Chesboro & Kermack is a success. It is handling 50 tons daily.

Georgetown.—Smuggler mine at Silver Plume is shipping 350 tons of ore monthly to the Hudson mill at Idaho Springs. Concentrate carries 50% zinc, 60% lead, and 150 oz. silver per ton. Rich ore is also shipped direct to smelters. Thirty men are employed.

The Wasatch Colorado company is employing 60 men at the Mendota mine. The 70-ton mill is yielding high-grade zinc and lead concentrates.

In the Terrible mine of the Denbigh Mining Co. are 14 levels 70 ft. apart. There are 35 men employed in reopening workings. No. 11 level is yielding good lead-silver ore.

Silverton.—Ross Mining & Milling Co., controlling the Champion mine, has made sub-leases to Cassagrande & Co. and an independent operator, who have made shipments to the Durango smelter.

The Lackawanna operators, known as the D. L. & W. Mining & Reduction Co., have leased the Silver Lake mill. The Precious Metals Mining Co. recently reduced its capital from \$5,000,000 to \$1,000,000.

The Zuni mine has been leased by Jackson & Anderson, who are cleaning out the tunnels, and will drive another to the main vein of the old Zuni mine. The property has been one of the best producers in the district, and is expected to keep up its reputation.

IDAHO

Adair.—The Richmond M. M. & R. Co. resumed hauling of ore by tram last week, about three carloads weekly. Thirty men are employed.

Kellogg.—Caledonia Mining Co. pays 3c. per share on May 6, equal to \$78,150.

Kingston.—An option on 1,100,000 shares in the Hypotheek Mining & Milling Co. at 15c. each has been taken by J. K. George of New York, according to J. H. Kern, managing director. The sum to be paid under the terms is \$165,000. The option may be exercised on or before August 15. The capital is 2,000,000 shares. The property is in the Coeur d'Alene region, and has been developed to a depth of 1200 ft. The mill is of 200 tons capacity.

Pierce.—The dredge which has been working near here for some years has been moved to Orofino creek near Gold Dollar, and should be in operation in May. H. R. Bailey is in charge.

Wallace.—Labor shortage in the Coeur d'Alene region continues, the estimate being 1000 men.

A joint tunnel may be driven from Beaver creek under Sunset peak to develop the Sunset claims of W. A. Clark and those of the Sunshine Mining Co. The Sunset orebody would be cut at a depth of 1500 ft. below the shaft bottom, which is 1000 ft. deep.

Wardner.—The Stewart Mining Co. contemplates retreating by flotation old tailing amounting to 200,000 tons.

KANSAS

Galena.—Drilling here has proved that the future of mining will depend on deeper work. Several companies did some deep work. The Wayland Mining Co. is an instance of getting ore as deep as 300 ft. The log of one hole is as follows, in feet:

Character of ground	From	To	Thickness
Surface and hard white flint	..	59	..
Softer flint with good ore	59	69	10
Harder flint with good ore	69	84	15
Hard white flint with 'shines'	84	114	30
Soft ground	114	121	7
Hard ground	121	181	60
Lime with some flint	181	234	53
Spar ground with good ore assaying			
for 40-ft. sample from each 4 ft.,			
making an average of 16.8% zinc	234	274	40
Lime with good flint 'shines'	274	296	22
Lime	296	300	4

MICHIGAN

Houghton.—Calumet & Hecla is using all the steel suitable in its old coal-dock on Torch lake for making tanks and trays in the flotation department of its Hecla mill.

Mass Consolidated Mining Co. in 1917 received \$1,045,502 from copper sales, plus \$16,816 from sundries. Expenditure totaled \$796,906, leaving a profit of \$265,413. Dividends (three of \$1 each) absorbed \$291,951. After deducting betterments, taxes, etc., the balance carried to 1918 was \$321,372. The year started with \$449,255. The superintendent, E. W. Walker, states that 4364 ft. of work was accomplished. Miners decreased from 409 in January to 232 in August, then gained to 372 in December. Results were satisfactory. The Evergreen lode yielded a good deal of mass copper. Reserves increased appreciably. The mill

dressed 244,671 tons of ore, averaging 16.29 lb. copper per ton, yielding 3,984,616 lb. of copper. The cost was 19.81c. per pound.

MISSOURI

Butterfield.—Drills in this district, about 40 miles south-east of Joplin, in Barry county, have cut good zinc ore—4.47 to 5.12% blende. A new mining field is possible.

MAP SHOWING RELATION OF BUTTERFIELD ZINC DEPOSITS TO JOPLIN.

Ore occurs in blue flint and disseminated formation at depth of 100 ft. It carries no lead. The Missouri Mining & Investment Co. has erected a 250-ton mill.

Joplin.—Production of the Missouri-Oklahoma-Kansas region last week was 9222 tons of blende and 1435 tons of lead, averaging \$42 and \$81 per ton, respectively. Total value was \$502,907, making \$7,702,228 for 16 weeks. Oklahoma contributed \$326,742 to last week's total.

Waco.—Drilling on the Nicholas land in the Waco-Lawton field has exposed 50 ft. of 40% blende ore.

Tom Hale Lead & Zinc Co. is to erect two mills—250 and 300 tons capacity—one in this field and the other at Donthat, Oklahoma. T. D. Hale of Oklahoma City is president.

MONTANA

Marysville.—The new gold-silver-lead ore in the Bell Boy mine near Marysville is considered the best made here in years. The shoot was found in cross-cutting the vein, which is 40 ft. wide. It was found by lessees at a depth of 150 feet.

In Lump gulch, Jefferson county, the Amalgamated Silver Mines Co. has completed a shaft to 250-ft. depth. A cross-cut to the vein, which is 8 ft. wide, shows a streak of silver ore assaying \$100 per ton. Control of property recently passed to Denver and Eastern people. The shipping point for this mine is Clancy, two miles distant.

The Mt. Washington mine is developed by a 3600-ft. adit to a depth of 800 ft. Thirty tons of lead ore is sent to the smelter daily, the most that the smelter will take.

Helena.—Stationary engineers are on strike in the Helena district, and mines are being closed.

NEVADA

Alpha.—Ore assaying \$80 in zinc and \$30 in lead has been uncovered seven miles from Alpha, a station on the

Eureka and Pallsade railroad, by Bryon Wilson, W. S. Rippey, T. J. Dron, and H. P. Herd of Manhattan. The deposit has been opened to a depth of 60 ft. and traced on surface for 2000 ft. Arrangements are being made for shipments.

Goldfield.—At a depth of 750 ft., Grandma Consolidated has cut a water-channel. Sinking continues with an additional shift.

The Montezuma silver district, 10 miles west of Goldfield, is attracting attention by the rich silver-lead ore being mined. The Montezuma Silver Mines Corporation and lessees appear to be getting satisfactory results.

The Pioneer Consolidated Mines Co., at Pioneer, is to be re-organized. Two of the eleven claims have produced a considerable quantity of good ore.

National.—Lessees, Carl Stolfelt and Sam Watkins, at the National Mines property shipped 166 lb. of gold ore, valued at \$5000, last week to the Selby smelter. This is a reminder of old times. Other lessees are busy in exploration.

Rand.—Jumbo Copper Mountain company, subsidiary of Jumbo Extension at Goldfield, reports encouraging results. At depth of 300 ft., No. 3 shaft passed through the contact zone, exposing 8 ft. of sulphide ore assaying 5% copper. L. L. Dellinger is in charge.

Reno.—Uvada Mining Co., operating in Esmeralda district of Washoe county, sold ore worth \$1260 in 1917. Total receipts were \$5861. Expenditure at mine was \$3505.

Virginia City.—All mining companies on the Comstock granted a wage increase last week, after holding conferences with representatives of the Miners' Union. Miners will receive \$5 per day, and shovelers and carmen \$4.50. Mechanics and other surface workers will receive a flat increase of 50c. daily. The wage-scale is lower than that prevailing at Tonopah and Rochester, but is higher than at Goldfield and most other camps.

Union Consolidated paid 5c. per share on May 11, making \$60,000 for the current year.

Compressed-air locomotives will be used in the Con. Virginia to haul ore to the Union Con. shaft, whence it will go to the Mexican mill.

NEW MEXICO

Deming.—The Sierra Blanca district, of Sierra county, is noted for the richness of its gold and silver ores. The Bi-Metallic M. & M. Co.'s mine's deepest shaft is 400 ft., with 1500 ft. of development. Ore is worth \$27.90 gold and silver per ton. Equipment includes a 20-hp. Alamo gas engine, an Ingersoll-Rand air-compressor and jack-hammer drills. M. S. Nord is general manager.

Kingston.—C. T. Brown, of Socorro, general manager for the Empire Zinc Co., has completed surveys of the old South Percha mines, 3½ miles south of here, and has started development. Rich silver ore is being stacked for shipment.

Mogollon.—Re-building of the Socorro M. & M. Co.'s mill will not be completed until July. It will be on the old foundation and as nearly fireproof as possible, being of steel and concrete. The carpenter-shop, planing-mill, saw-mill, and store-house are finished. The steel frame for hoist is up. This company recently purchased the 29 claims and 40 acres of mill-sites from the Mogollon Gold & Copper Co., so its total holdings are now 1600 acres. The mill will include two Hardinge ball-mills, one 13 by 24 Blake crusher, and one 15 by 20 Blake crusher, two Chalmers & Williams tube-mills, and five pachuca agitators for cyanidation. De La Vergne oil engines are used, four totaling 1000 hp. D. B. Scott, late with Inspiration Consolidated Copper Co., is general manager.

The Mogollon Mines Co.'s greatest depth of workings is

1800 ft. The main adit is nearly 3000 ft. long. There are over five miles of underground workings. Equipment consists of an electric hoist, Ingersoll-Rand compressor, De La Vergne oil-engines, electric power, 40-stamp mill and cyanide plant, capacity being 165 tons per day. There are 125 men employed. S. J. Kidder is general manager.

OKLAHOMA

Picher.—Production of Oklahoma mines last week was 5791 tons of blende and 1004 tons of lead, valued at \$326,742.

Black Hawk Mining Co. is moving No. 3 mill of the Onamena company at Duenweg, Missouri, to its property south-east of Picher. Ore is said to carry 25% blende.

OREGON

Gold Hill.—Shortage of skilled miners and millmen prevents resumption of work at the Millionaire, Nellie Wright, and other smaller gold mines in this district. Rich ore has been uncovered from an 80-ft. raise, 400 ft. below the surface, in the Ray and Haft mines three miles north of Gold Hill. This is operated by J. W. Davies of Sacramento, California.

Grants Pass.—The 13 chrome deposits in the Waldo district controlled by R. J. Rowen and associates have 27 auto-trucks employed hauling ore. Five cars daily are sent from the shipping point at Waterville. This quantity is to be increased.

TEXAS

Austin.—J. P. Nash, of the Bureau of Economic Geology and Technology of the University of Texas, has returned from Val Verde county, where he investigated the manganese deposits. He reports that there are two properties being prospected, and 40 carloads is available. The ore carries from 5 to 40% manganese. No estimate of quantity is possible so far. The ore is found mostly in caves, and consists of large porous boulders in many instances. The beds are close to the Rio Grande, and adjacent to the Southern Pacific railroad.

Orla.—Texas Sulphur Co. has finished erecting buildings at its sulphur deposit near here, and awaits equipment ordered. Company owns surface rights to 1331 acres. On part of this land the sulphur beds outcrop and may be mined by steam-shovels. H. M. Tibbett is secretary at Orange, the headquarters.

UTAH

Alta.—The Alta Tunnel & Transportation Co.'s tunnel was in 3228 ft. on April 1, 325 ft. from a point directly under the outcrop of the Prince of Wales vein. An assessment of 1c. per share has been levied.

Dugway.—Preliminary work has been started by the Dugway Smelting Co. Foundations are being prepared and wells sunk for water. The first unit of the smelter is to be of 100 tons capacity.

Provo.—Diamond-drilling is under way in the Bonneville tunnel of Jesse Knight. Face is in 5100 ft. from portal, at depth of 2500 ft., and drill is boring horizontally in ground 1500 ft. from end of adit. So far this adit has found little ore.

Tintic.—Labor disputes here have been settled, but the mines are short of men, probably 30% low.

WASHINGTON

Republic.—Ore shipments from Lone Pine-Surprise company for 21 days in April amounted to 15 carloads. From April 22 daily shipments were to be 50 tons.

Northport Smelting & Refining Co. has purchased the Blacktail claims from the Hope company.

No. 2 diamond-drill hole on the San Poil vein is nearly finished.

Spokane.—The Spokane tin mine on Moran prairie, south of this city, has been bonded to F. C. Bailey and others for three years. There is said to be 8 ft. of ore on the surface. A shaft is down 152 ft. On 100-ft. level 180 ft. of work is estimated to show ore worth \$40,000. Nothing has been done since 1907.

CANADA

British Columbia

Princeton.—Pending a decision regarding income-tax, construction of the 14-mile branch of the Kettle Valley Railroad from Princeton to Copper Mountain is to be suspended. W. P. Tierney has the contract.

Revelstoke.—Lanark Mines Co. is to spend \$25,000 in constructing a dam and power-plant. Two new shoots of ore were opened in the mine during the winter. W. B. Dornberg is manager.

Sandon.—The Slocan Star Mines is to be re-organized as the Silversmith Mines, with a capital of \$750,000. The property is fully equipped.

Victoria.—A seventh interest in Coast Copper Co., subsidiary of Consolidated M. & S. Co., operating on Vancouver Island, has been sold by M. W. Bacon and W. E. Cullen to G. E. Snyder and others of Spokane for \$150,000. This equals about \$5 per share. Development and equipment of property cost \$350,000. Ore-reserves above 700-ft. level are 2,940,000 tons, assaying 2% copper and \$1.25 per ton in gold and silver. Vein on this level is 24 ft. wide. Railroad survey from Quatsino sound to mine, 12 miles, has been surveyed. J. J. Warren is general manager, and W. M. Archibald mine manager.

The policy of the Provincial government in regard to taxation of mining properties was disclosed on April 19. The Hon. John Hart, Minister of Finance, introduced the bill which, no doubt, will become law. It provides that mines shall be taxed on income or 2% on the assessed value of the ore removed, whichever is the greater. Properties coming under the income tax will be allowed for depreciation of plant up to 15%, the exact percentage in each case being left to the Minister to decide. Salaries paid to directors and officers will be deducted when the recipients are resident within the Province and, therefore, are paying income tax themselves. It also is proposed to exempt from the personal income-tax dividends from mining companies when the tax has been paid at the source. Gold-mining companies will be taxed on profits only, in view of the fact that the price of gold is fixed, while the cost of production has greatly increased. The various deductions just enumerated apply here as well. A tax of 37½ cents per ton is placed on iron ores, but this is more than offset by the bounty of \$3 per ton on pig-iron produced in the Province from local ores, and the smaller bounty on pig-iron produced in the Province from foreign ores. All these mining taxes and the deductions affecting them date back to January 1, 1917, and as soon as the amendments are law the taxes for 1917 and 1918 will be levied and collected.

Ontario

Cobalt.—Kerr Lake produced 207,100 oz. silver in March, and pays a dividend of 25c. per share, equal to \$150,000, on June 15.

Silver yield of Nipissing in March was valued at \$308,048. This came from 94 tons of high-grade and 7234 tons of low-grade ore. The refinery shipped 525,932 oz., partly custom metal.

Kirkland Lake.—First clean-up of the Lake Shore company's new mill gave gold valued at \$40,000 from a 23-day run. There are 56 men employed.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Arthur L. Pearse is in New York.

Horace V. Winchell is at Salt Lake City.

Robert M. Thompson is at the Fairmont hotel.

Franklin W. Smith, of Bisbee, is at Redlands, California.

J. A. Martin has left Alaska and is now at Cleveland, Ohio.

C. S. Corbett is with the U. S. Shipping Board at Washington.

W. H. Sirdevan is returning to the United States from Nicaragua.

R. B. Watson has returned from Phoenix, Arizona, to Cobalt, Ontario.

James A. Block is now with the U. S. Coal & Coke Co. at Gary, West Virginia.

James W. Neill has gone with a prospecting expedition into north-western Canada.

Remschlaer Toll has returned to San Francisco, having completed a mill near Kingman, Arizona.

Bernard MacDonald has left for Guanajuato, Mexico, where he expects to remain for several months.

J. R. Griffin succeeds M. A. McCullough as manager for the Rico Argentine company at Rico, Colorado.

E. H. Clausen, Captain in the Engineer Officers Reserve Corps, has been ordered to Camp Lee, for training.

H. R. Wagner has been appointed representative of the American Smelting & Refining Co. on the Pacific Coast.

H. R. Norsworthy has gone to take charge of the Grau chrome mine at Red Bluff, California, for Samuel H. Dolbear.

William B. McPhee, formerly research chemist at Timber Butte mill, Butte, Montana, is now mill superintendent for the Como Con. Mines Co., at Como, Nevada.

HELPING THE UNFORTUNATE

A friend sends us a statement of account from Perugia, in Italy, showing how much good was done with a 100 dollars, when exchanged into Italian currency, making 917 lire. We reproduce the statement thinking that at least one of our readers would like to do a similar \$100 worth of kindness to the victims of warfare in beautiful Italy. Any subscription sent to the Editor will be forwarded and properly acknowledged.

Account of 917 Lire Received from H. R. to be Spent on Refugees and Wounded Soldiers

Perugia, March 1918.

	Lire
48 pillow-cases for hospital.....	117.00
18 sticks for crippled soldiers.....	34.00
22 pillows for wounded.....	132.00
9 pairs of good crutches.....	96.00
24 pairs of ordinary crutches.....	84.00
13 woolen shirts for wounded.....	125.00

THE METAL MARKET

METAL PRICES

San Francisco, April 30

Aluminum-dust, large and small lots, cents per lb.	65—70
Antimony (wholesale), cents per pound	13 1/2
Copper, electrolytic, cents per pound, in carload lots	23 1/2
Copper, electrolytic, cents per pound, in small quantities	24 1/2
Lead, pig, cents per pound	7 1/2—8 1/2
Platinum, pure and with 10% iridium, per ounce	\$108—\$116
Quicksilver, per flask of 75 lb.	\$115
Spelter, cents per pound	9 1/2
Zinc-dust, cents per pound	17 1/2

ORE PRICES

April 30

Antimony, 45% metal, f.o.b. California, per unit	\$110
Chrome, 38% and over, California, per unit	\$1.25—\$1.50
Magnetite, crude, California, per ton	\$7.00—\$8.00
Manganese, 40 to 50% Mn, Hazen, Nevada, cents per unit	92—110
Manganese, 48%, New York, per unit	\$1.20
Tungsten, 60% WO ₃ , California, per unit	\$24
Molybdenite, per lb., 85% MoS ₂	\$1.80
Pyrite, domestic, New York, per unit of sulphur, cents	28

EASTERN METAL MARKET

(By wire from New York)

April 30.—Copper is unaltered. Lead is inactive and easier. Spelter is quiet though steady. Platinum is not quoted.

SILVER

Below are given official or 'ticker' quotations, in cents per ounce of silver 999 fine. The actual figure at which the metal is bought and sold is a matter of negotiation, and is not available, but the prices given indicate such approximately. Premiums are paid, up to 3c. per oz. See 'M. & S. P.' of March 23, 1918, for full details. From now on the price of the metal is fixed at \$1 per ounce.

On April 23 the Silver Bill was signed by the President, fixing the price at \$1 per ounce.

Silver exported from San Francisco during March was valued at \$9,951,351. Of this, \$7,652,720 went to India, the remainder to China.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.67c. for small lots, effective until June 1, 1918. Quotations in cents per pound are as under:

A Government embargo has been placed on importations of lead in order to save freight space.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. In February 1918 the Government fixed prices for grade A spelter at 12c. per lb. for itself and the open market. This grade constitutes only a small proportion of the total output. Lower grades can make their own prices as usual. Sheet-zinc is fixed at 15c. per pound.

Cable advice from Australia states that the British government will purchase all zinc concentrate produced in the Commonwealth during the War and for 10 years after.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking 40% of the United States quicksilver output, paying thereof \$105 per flask. Outside of this business the competitive market can make any price as usual. Prices, in dollars per flask of 75 pounds:

June	42.07	61.93			42.55	85.00	

The report that Holland had put an embargo on the export of tin from its East Indies is denied by that Government. What was done was the issuing of licenses, as is customary in England.

It is reported that considerable quantities of tin en route from San Francisco to the East have been 'lost,' and the Tin Committee of the New York Metal Exchange is investigating the matter.

Eastern Metal Market

New York, April 24.

Inactivity still pervades all the markets and there is little news of decided interest except in tin.

Copper market conditions are unchanged.

The tin market is at a deadlock, and almost no business is being transacted. Prices are soaring.

Lead is very quiet and a little easier.

Zinc continues to show weakness.

Antimony is unchanged.

In the iron and steel market the operating conditions are improving daily. The leading producer in the Pittsburgh district had 96% of its rated blast-furnace capacity active last week and 98% of its bessemer and open-hearth steel capacity. The Carnegie Steel Co. is now giving practically 100% of its rolled product to war requirements. Other Central Western plants are giving 75 to 90% of their shipments to the Government. The bar-wire needs of the Allies have swelled to 110,000 tons, of which 60,000 tons will go to Italy and 50,000 tons to France. Car scarcity is still acute, particularly in the South, where tens of thousands of tons of pig-iron, which buyers need, is accumulating at the furnaces. The large order for cars is still delayed and valuable time is being lost.

COPPER

The meeting of Government representatives and copper producers to confer as to the price of copper after June 1 is to be held earlier than expected. It is scheduled for May 1. There are quite a number who predict that the present price of 23.50c. will be advanced to 25c. per lb., while there are some who expect no change. The agitation for a higher price the last few weeks, based on increased costs of refining in particular, is believed to have had the effect of at least preventing a reduction in the present price. Sales are being made for delivery beyond June 1, and some before that, the price to be the Government's at that time, which is considered significant. There is no change in fundamental conditions. Production is proceeding at a high rate, and sales and distribution are apparently satisfactory under the control of the Copper Producers' Committee. Copper exports to March 1, 1918, have been 68,691 tons, of which France has taken 36,654 tons and the United Kingdom 21,318 tons, with \$939 tons going to Italy.

TIN

The conference in Washington last week, mentioned in our last letter, was of considerable importance. Representatives of the solder, babbitt, tin-plate, bronze, and all other tin users were present. The meeting had for its chief object the consideration of means to conserve the supply of tin for the Nation. It was stated that the estimated needs of the country for the year amounted to 90,000 tons, not including 12,000 tons for special heavy work, and that this total must be cut down to about 74,000 tons or practically 25%. The consumers were urged to conserve tin wherever possible by using low-grade metal in such mixtures as feasible, so as to save the high-grade tin for more vital uses. Because of a lack of offerings the tin market in general has come to a standstill. Very little business has been done. That which is reported has been mostly Chinese tin for April-May shipment from China at unheard-of prices, reaching up to 85c. per lb. There is scarcely any Straits or Banca tin offered. The only feature of improvement is the fact that licenses are being obtained a little better, though very slowly, in England for shipment of English tin to American consumers. Spot tin is quoted nominal at 88c., New York, but almost unobtainable. It is reported that one small lot

brought \$1.02 per lb. in the last few days. Arrivals to date have been 420 tons, with 5000 tons estimated afloat. Prices in London are very high again. Yesterday spot Straits was quoted at £343 10s. per ton, or £20 higher than a week ago.

LEAD

General conditions are practically unchanged since last week. There is still a little more lead offered than the market is ready to absorb, and as a consequence prices are slightly lower at 6.90c., New York, or 6.75c., St. Louis, for early delivery. Most large producers are well sold up for April-May shipment, and the plant of one large producer is still closed because of labor troubles. The offerings referred to come from small producers. There is very little activity, and the entire market is quiet. There is some inquiry for export.

ZINC

There is not much activity in zinc. If anything, the market is weaker, due almost entirely to underselling by some producers. With not much business actually transacted, and with various quotations being made, the actual levels are hard to quote. The quotation for early delivery and for May-June shipment is about 6.62½ to 6.75c., St. Louis, or 6.87½ to 7c., New York, at which prices some sales have been made for May-June. For July-August shipment about ½ to ¾ higher is asked and has been obtained on some small sales. Reports for the first quarter, referred to briefly last week, show also a 4000-ton increase in stocks on hand March 31 as contrasted with December 31, 1917, that producers having 195,000 retorts had 112,000, or 57%, operating April 1. Production in the first quarter this year was 136,000, as contrasted with 183,150, 187,322, 161,668, and 153,296 tons, respectively, in the four quarters of 1917.

ANTIMONY

Demand is light and quotations are unchanged at 12.75 to 13c., New York, duty paid, for Chinese and Japanese grades.

ORES

Antimony.—The ore is available at \$1.75 per unit, but there is only a very quiet market.

Ferro-manganese: An interesting new phase of this market is the Government proposal to make the standard domestic ferro-manganese a 70% alloy, instead of 80% as now, and to make the standard domestic spiegeleisen 16% manganese. No official announcement has been made, but one American maker is now quoting \$250, delivered, for 70% ferro-manganese, with \$4 per unit extra above or below this, and \$70 at furnace for 16% spiegeleisen with \$3.50 per unit extra for each unit above this. The Government's object in this is to encourage the use of low-grade domestic manganese ores.

The new Federal government order prohibiting all importations by sea of ferro-manganese means the cutting off of all British alloy. This amounts at present to almost 2000 tons per month. Its loss is not viewed with equanimity in the trade.

Molybdenum.—There is practically no market. The prohibition of all importations of molybdenum will not have much effect, as little has been coming by vessels.

Tungsten.—Quotations are unchanged at \$20 to \$24.50 per unit in 60% concentrates, depending on the grade, and a fairly active business is reported for the past week. Ferro-tungsten is quoted unchanged at \$2.25 to \$2.40 per lb. of contained tungsten.

Company Reports

MYSORE GOLD MINING CO.

Property: extensive property and treatment plants in the Kolar field of India.

Operating Officials: John Taylor & Sons, managers; R. H. P. Bullen, superintendent.

Financial Statement: during 1917, gold sold, etc., realized £803,731 (\$3,900,000). All charges amounted to £399,435 (\$1,920,000), leaving a profit of £404,296 (\$1,930,000). The year started with a balance of £111,665 (\$537,000) and ended with £83,044 (\$398,000). The reserve fund is £150,000 (\$720,000); cash and gold, £243,624 (\$1,170,000); and stores, £132,817 (\$638,000).

Dividends: £259,250 was paid last year, making £8,649,594 (\$41,520,000) since 1886.

Development: exploration in 1917 exceeded that of 1916 by 1594 ft. The Edgar shaft is 3808 ft. deep and McTaggart's 3003 ft. Results were generally good. Reserves are estimated as 939,000 tons, a decrease of 80,000 tons.

Production: 307,126 tons of ore, 261,299 tons of tailing, and 262,156 tons of slime yielded gold worth £842,057 (\$4,035,000). Total since 1884 is 5,138,250 tons of ore and 5,026,168 tons of tailing, yielding £18,739,343 (\$90,230,000).

CERRO GORDO MINES CO.

Property: mine near Keeler, Inyo county, California.

Operating Officials: L. D. Gordon, general manager; J. C. Climo, superintendent; John Nelson, in charge of aerial tram; H. G. Rose, mine office.

Financial Statement: cash receipts during 1917 totaled \$609,554, including \$112,377 brought forward from 1916. Operations cost \$214,055. Deducting cost of new property, Liberty Bonds, and dividends, cash carried forward for 1918 was \$79,699.

Dividends: four absorbed \$225,000.

Development: this amounted to 4933 ft. The main source of ore was the deposit south of the shaft. Between the 700 and 900-ft. levels the shoot was cut off by a fault, but its extension is being sought. The 400 and 700-ft. levels are now supplying ore shipped. The Spear mine adjoining the Cerro Gordo is being explored under option. It has promising indications.

Production: this consisted of the following:

Product	Tons	Lead, %	Silver, oz.	Gold, oz.	Zinc, %
Lead ore..	6,088	30.27	18.73	0.02
Zinc ore..	5,417	31.14
Old slag..	14,034	11.17	3.32

The metal contents were therefore 3,686,387 lb. lead, 3,373,548 lb. zinc, 128,075 oz. silver, and 123 oz. gold.

Costs: these totaled \$15.03 per ton of ore mined, which averaged \$35.02 per ton.

JUDGE MINING & SMELTING CO.

Property: mine and works at Park City, Utah.

Operating Officials: G. W. Lambourne, general manager; O. N. Friendly, general superintendent.

Financial Statement: sales of ore returned, \$953,729. With sundries, receipts for 1917 were \$992,864. All expenses totaled \$934,314, including \$357,957 for the new zinc plant. Balance forward from 1916 was \$555,290, and that to 1918 is \$132,840.

Dividends: four absorbed \$480,000. This makes \$2,070,000 to date.

Development: from the 500 to 1900-ft. level, on three vein systems, exploration advanced 7482 ft. An unknown ore-zone was proved, by prospecting after a study of geologic conditions. One of the largest bodies of shipping ore was thus discovered.

Production: the 380-ton mill dressed 63,387 tons of ore, producing 11,861 tons of lead and 5526 tons of zinc concentrates. Crude ore sold was 7247 tons. Metal contents were as under:

Product	Lead, %	Copper, %	Zinc, %	Silver, oz.	Gold, oz.
Crude ore sold.....	14.26	1.10	10.03	35.18	0.023
Lead concentrate.....	24.59	1.03	10.09	26.62	0.029
Zinc concentrate.....	4.30	1.30	43.11	19.86	0.020

The yield in 1917 was 7,919,720 lb. lead, 428,000 lb. copper, 585,680 oz. silver, and 532 oz. gold.

Owing to lack of essential chemicals for the electrolytic zinc works, no spelter was sold. A shipment was made in March 1918.

AMERICAN SMELTING & REFINING CO.

Property: mines, smelters, and refineries in the United States, Mexico, and South America.

Operating Officials: general managers—C. W. Whitley, in Utah; L. G. Eakins, in Colorado; C. L. Baker, in Mexico; R. T. White, in Chile; Kuno Doerr, South-Western department; H. A. Guess, managing director of mining department; W. M. Drury, manager of mining in Mexico; E. A. Behr, lead sales agent; and H. M. Brush, assistant manager of copper sales.

Financial Statement: revenue and expenditure may be summarized as under:

Metal sales and manufactures.....	\$428,401,471
Mining properties, etc.....	15,578,830
Balance and loans at January 1, 1917.....	19,941,492

Total income.....	\$463,921,793
Paid for ore, bullion, expenses, and taxes.....	426,017,668
Property expenditure.....	6,586,274
Advances, acceptances, A. S. S. Co. bonds purchased, interest, etc.....	4,014,356
Dividends paid.....	8,982,525

Total charges.....	\$445,600,825
Balance, loans, and Liberty Bonds (\$6,419,250) at December 31, 1917.....	18,320,968

Total.....	\$463,921,793
------------	---------------

The profit aggregated \$25,035,938, which is \$206,359 less than that in 1916. Corporate taxes were \$2,864,005 greater. Deducting depreciation and depletion of ere-reserves, appropriation for insurance and pensions, and sundry charges, the net profit was \$18,495,625.

Dividends: preferred stock received \$4,712,666, equal to 7%; and common stock, \$4,269,860, or 6%, plus 1% extra Red Cross distribution.

General: metal production of the company will be published in another issue of this journal. All supplies are costing from 50 to 150% more than normal. Labor has been short and demanded increased wages. The company is suffering from an entire lack of economic law, as the Government is fixing the value of such metals as the company produces. The Mexican situation, regarding the A. S. & R. properties, is only fair. Plant expenditures totaled \$6,605,691, of which \$4,700,000 was spent at Garfield, El Paso, Hayden, Baltimore, Perth Amboy, and Tacoma. The smelting and refining capacity of the company is now 1,500,000,000 lb. per annum, the present output being 1,000,000,000 lb. Metal stocks are valued at \$36,339,520, a gain of \$8,861,849. Large expenditures were made for safety devices. Plant inspectors are subjected to more rigid rules. Accidents decreased 25% during 1917. Safety and hospital charges, etc., totaled \$340,000; plus \$100,000 for erection of club-rooms and community houses. The company is insuring 6062 employees for policies totaling \$5,037,500. Pensions were granted to 34 beneficiaries in 1917, making 232 in all.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

ROSS AUTOMATIC DROP-BAR GRIZZLEY-FEEDERS

The difficulties of feeding and screening coarse ore are well known to mine and mill operators. Probably at no other point in a plant are the sledge-hammer and the repair gang so much in evidence. It seems strange that so simple an operation as feeding and screening should give trouble, until one examines closely the usual cause of the mischief, that is, the strangely shaped 'neutral' pieces, which will neither pass through the grizzly nor be carried over. This source of trouble has been completely eliminated in the Ross automatic drop-bar grizzly-feeders, designed by Wil-

liam Ross, who, as mechanical engineer on mines in South Africa and America, has for years been a participant in many sledge-hammer episodes. In addition, these machines have overcome other well-known difficulties, such as the blocking of large ore at the bin-opening, and irregular rushes of ore in the chute with the consequent inefficiency of the grizzly itself and of the machine being fed. The device is covered by patents.

ROSS ROTARY DROP-BAR GRIZZLEY-FEEDER.

TRAVELING TYPE OF DROP-BAR GRIZZLEY.

liam Ross, who, as mechanical engineer on mines in South Africa and America, has for years been a participant in many sledge-hammer episodes. In addition, these machines have overcome other well-known difficulties, such as the blocking of large ore at the bin-opening, and irregular rushes of ore in the chute with the consequent inefficiency of the grizzly itself and of the machine being fed. The device is covered by patents.

The accompanying illustrations show the Ross rotary and traveling types of machine, consisting essentially of an apron of equally spaced bars, which are fed slowly forward under the lip of the bin-opening. The quantity of ore drawn away is determined by the speed of the moving bars and the relative position of the heavy flexible door. The main bin-opening is made quite large, and when a big piece comes through the gate it will swing outward temporarily to allow it to pass, returning afterward to its normal position. On reaching the discharge point, each alternate grizzly-bar

zley-bars are socketed in the flanges of the cheek-plates and the secondary grizzly-bars are linked to the main bars, and supported at the ends during the screening operation by an inner shoulder on the cheek-plates. Arrangements are provided so that the grizzly-space can readily be adjusted within a wide range. The bars can be removed individually. In the traveling type of machine, the flanges of the rotary type are replaced by chains with hardened pins, on which the grizzly-bars are socketed. For heavier service the chains are of the roller type and track-rails are provided. In all cases the machines are designed for continuous running without attention.

Over a dozen machines are already installed with screen spaces from 1 in. to 3 in., and negotiations are being completed for the installation of heavier machines, notably one with 8-in. screen-spaces. This machine will handle large run-of-mine ore, at the rate of 350 tons per hour when the bars are moving at a speed of 30 ft. per minute. The bars

are 5 in. diam. and the figures show that 25 sq. ft. of grizzly surface will be presented to each ton of ore. The mining world has responded promptly to the unique advantages offered by these machines, and manufacturing facilities are in working order to meet the demand.

Further particulars can be obtained from the Ross Engineering Co., 908 Eastern Townships Bank Bdg., Montreal, Canada.

THE MEYER DRY ORE CONCENTRATOR

In presenting the Meyer dry ore concentrator to the mining world it is with the realization that it is still far from being perfect, but with the conviction that the principle upon which the process is based is absolutely sound, and with the knowledge that there is a positive demand and a real need for a concentrator of this class. While in a class by itself in arid districts and high localities, this concentrator will quickly prove its merit wherever it may be used, and in placing it upon the market it is with the fullest confidence of meeting the approval of every progressive miner and of the mining engineering and metallurgical professions.

The Meyer dry ore concentrator, even on the most difficult

GENERAL VIEW OF MEYER CONCENTRATOR

of complex sulphide ores, and oxide and carbonate ores, as copper carbonates, has never averaged less than 85% of the total content of the ore. The Meyer concentrator is constructed entirely of steel, the frame of heavy channel and angle iron, and the cylinders of heavy-gauge sheet steel. It will last a life-time with practically little or no repair. It uses any kind of power and therefore can be operated anywhere that mining can be successfully conducted. It operates entirely dry, requiring no water whatever, and it can be quickly erected by any ordinary handy man. It requires no skilled labor to operate it. Every section is a complete concentrator in itself, generally termed a 'cylinder', being the exact duplicate of every other section. Each section will have a capacity of from three to six tons per 24-hour day depending upon the ore and the amount of rock to be eliminated; as many sections being ordered as capacity is desired. Additional sections may be added as the tonnage increases without stopping or interfering with the sections already operating.

The Meyer dry ore concentrator is a series of inclined revolving hollow cylinders, made of heavy-gauge sheet steel, and connected by an air-tight compartment with an ordinary exhaust fan. Each complete section, or cylinder, is a complete concentrator in itself, entirely separate from the other sections, having its own individual driving mechanism, feed,

exhaust-fan, and its own individual regulating valves. Each section occupies approximately two feet of floor space in width, while the length is exactly nine feet. The width of the various sections being only determined by the closeness of placing the exhaust fans. This concentrator is designed so that each separate section, or cylinder, is receiving the ore of only one size. In the case of an ore classifying into 20 sizes, for example, a very convenient installation would be 20 sections, thus permitting all of the 20 different sizes being fed through the concentrator at the same time, each into a separate and independent section.

The Meyer system is dustless. Although the ore will be crushed in a dry state, by connecting up an ordinary exhaust fan, or one section of this concentrator, specially designed for this purpose, the suction of the fan can be regulated not only to remove all the dust, but also as many of the fine sizes as desired. In case the dust and fine contain sufficient mineral to warrant saving and treating, the air-current containing the dust and fine can be led into a larger room where they will be precipitated in direct proportion of the size of the pipe through which the dust is led into the room. The Meyer concentrator requires about one-half horse-power to operate the exhaust fan at the necessary speed, and to revolve the cylinders less than a quarter of a horse-power. In other words it requires less than one horse-power per cylinder. The capacity primarily depends upon the amount of rock to be eliminated. The suction of any cylinder is only able to suck up the amount of rock that that particular section is capable of removing. The capacity is conservatively stated to be from three to five tons of ore per day, but where the amount of rock to be removed is not so large, the capacity will be much greater. This concentrator is made by The National Milling & Refining Co. at Canton, Ohio.

CREOSOTE AS A WAR-TIME PRODUCT

The demands of the War have seriously affected the labor situation on the railroads. The high wages of the munition plants have attracted the men from the section gangs of the railroads and many of the laborers have entered the military forces of our country. These vacancies have not been filled in many cases and consequently the maintenance-of-way work is being done by a decreased number of workers. As an illustration of the decrease of labor, one of the divisions of a large Eastern railroad employed 544 men in section gangs in December 1912, and in December 1917 the personnel of these gangs totaled 358. Having a lessened number of employees with which to do the same amount of work as previously, the supervisors were confronted with the problem of eliminating some of the work and of getting greater results from the labor expended. One of the chief duties of the gang is to replace defective ties that have rotted through exposure and wear. This changing of ties requires a large portion of the time spent in repairing the road bed and consequently any saving in this work would decrease the amount of labor required to a considerable extent. The average length of life of a tie is about eight years, and with the enormous number of ties used on the railroads of America, this means an enormous number of replacements each year especially when one considers that there are over 2,310,000 miles of track operated by American railroads, and that the ties required in this stretch of steel amount to over 577,000,000. This means that there are over 90,000,000 ties replaced every year, and as the changing of each tie requires an hour's work a large amount of time is thus consumed.

The possibility of saving a large part of this time has caused the supervisors of railroads to order all ties creosoted before being placed in service. Creosoting doubles the life of the tie and proves a resistant against the ravages of climatic conditions and other forms of decay. The creos-

soting process consists of heating the tie to drive off the moisture and then immersing it in a bath of hot creosote. The creosote is absorbed into the cracks of the wood and when taken out of the bath, the tie presents a water-proof surface that will last for many years. The manufacturers of creosote in this country have perfected their product to suit the need of the railroads and as a result most of the large companies have made the use of creosoted ties standard, thereby saving thousands of hours of labor yearly.

THE NOMON—A CALCULATING DEVICE FOR CHEMISTS

By Horace G. Deming

The slide-rule has never been in such general use among chemists as among engineers, doubtless for the reason that

tended merely to indicate the method of using the chart, and the special advantages that it offers in chemical calculations.

To multiply two numbers together, find one of them, neglecting decimal points, on the scale at the left of the chart, called the principal scale. Find the other number, after dropping its first figure, on the inclined scale at the right. Connect the two points thus located by means of a straight line scratched on the under surface of a strip of celluloid that accompanies the chart. The product is read from the intermediate scale that is labelled above and below with the figure of the multiplier that has been dropped. Thus the product of 586.8 and 0.7419 is found by locating the first of these numbers on the principal scale, and 41.9 on the inclined scale. If the hair-line of the transparent

FOURTEENTH SECTION OF NOMON, REDUCED FROM 7 INCH BY $10^{1/2}$ INCH.

many of the calculations of chemistry demand a higher degree of accuracy than that obtainable with the ordinary form of this instrument. There seems to be a demand for an instrument at once more accurate than a slide-rule, and cheaper, handier, and more portable than a calculating machine. A calculating chart designed by myself, and published by the University Press, Urbana, Illinois, to which the name 'nomon,' that is, nomographic reckoner, has been given, seems to satisfy these requirements. It will multiply, divide, square, cube, and extract square roots and cube roots, giving results to four figures, with an average error of about one unit in the fourth place, a degree of precision about 5 or 10 times that of an ordinary 10-in. rule. For solving proportions it is not so convenient as a slide-rule, but one should remember that in an ordinary chemical proportion two of the terms can usually be combined in a single constant, thus reducing the calculation to a simple multiplication or division. In the construction of the nomon the logarithmic principle at the basis of the slide-rule has been abandoned entirely, and resort is had to a new combination of graphical principles. The present paper is in-

strip is placed to connect these two points, it will intersect the scale numbered 7 (the figure dropped from the multiplier) in the point 435.3, which is the required product. The decimal point is best located by inspection, though there is a rule for fixing its position mechanically, if desired.

Division may be performed by a process the converse of that just described for multiplication. Reciprocals may be read directly from the chart, to four, or even five figures. Auxiliary scales, placed just to the right of the principal scale, permit squares and cubes to be read directly, when points on the principal scale are connected with the point 00 of the inclined scale. Square roots and cube roots may be obtained by a converse process. Though the chart gives results directly to but four figures, its use may be combined with the ordinary methods of calculation, in such a way as to give verified products, quotients, or roots to six or seven figures, in a small fraction of the time otherwise needed. In order to attain the degree of precision just mentioned, it has been found necessary to subdivide the principal scale, and therefore the entire chart, into eighteen sections. Thus the fourteenth section, reproduced in the figure, covers the

range of multipliers from 550 to 600. A marginal index provides for instantaneous reference from one section to another. About three-fourths of the labor of disconnected multiplications and divisions falls on the last four sections.

All the scales of the chart were originally laid off on metal with a dividing engine, and all the calculations and methods of construction used in its design have been verified mechanically. In order to secure maximum legibility, special attention has been given to the method of subdividing the unit interval of each scale. In this respect the chart offers distinct advantages over the slide-rule, in which unit intervals subdivided into fifths are frequently confused by beginners with those subdivided into tenths. In most of the sections three digits of each result are given in plain figures—an additional safeguard against errors. The chart may be rolled up and carried in the pocket, and in spite of its increased precision is much less expensive than a slide-rule, the present edition selling for a dollar. Perhaps the most important advantage of the nomon is, however, to be found in the fact that it may be adapted very readily to individual requirements, by inscribing special factors along the margins of the chart, beside corresponding points of the principal or inclined scales. It is thought best to leave the location of such points to the individual user, in order that the chart may not be encumbered with data of little use to him personally. Thus points representing the common gravimetric and volumetric chemical factors, inscribed along the principal scale, may be used as constant multipliers. (The factor $\text{CaO}/\text{CaCO}_3 = 0.5603$ is indicated in the figure). A hole near one end of the transparent strip is set over a given factor and held in place with the rubber tip of a pencil, cut to a conical point. If the free end of the strip is now swung over the face of the chart, to pass through each of a series of weights or buret readings in turn, products or quotients may be read off almost as fast as an assistant can note them down. With the ordinary type of slide-rule, about half of the results of such a series of operations will lie beyond the limits of the scales, making necessary frequent re-settings, if the operations are carried out in order. Or the section concerned, printed separately on bristol-board, may be fastened to the wall or table-top, and the transparent index set permanently over the given factor by means of a thumb-tack.

DIXON'S GRAPHITE PRODUCTS IN MINING

When a quick, convenient, and positive cure for slipping is desired there is nothing better than 'solid belt dressing.' Traction-belt dressing is for use when there is time and opportunity for applying a paste dressing. It penetrates the fibre of the leather, strengthening it and bringing back vitality. If there is anything that will waterproof a belt, preserving it against the spatter of water, wet steam, and destructive chemical action, it is Dixon's traction-belt dressing.

Dixon's 'solid belt-dressing' should be used as a convenient dressing for leather, rubber, and fabric belts. The 'waterproof graphite grease' may be employed for the lubrication of cables, the use of which is extensive in mining. During the operation of re-making the cables they may be lubricated also. Probably most companies have what is known as a rope-house where this operation is performed. After all of the strands are taken out and thoroughly cleaned and wound on separate drums, they are then re-woven, and as the re-finished rope comes forth foot by foot, it is passed through an iron trough or 'mulligan,' as it is termed. This 'mulligan' has a false bottom to which is conducted live steam. The grease is placed in this and heated to a degree sufficient to melt it. Then the rope is passed through this solution. By following this operation, a thorough coating of lubricant is applied to all of the strands.

Another important use for 'waterproof grease' is on dredges. The endless chain of bucket type, with upper and lower tumbler bearings, requires a special method of lubrication to which Dixon's 'waterproof graphite grease' is peculiarly adapted. The uses for Dixon's 'silica-graphite paint' in this field are numerous. The chief of these is for smoke-stacks and other metal work subject to corrosion by acids, alkalies, gases, and the weather. Numbers of mining companies have used the 'silica-graphite paint' for these purposes and have had excellent satisfaction. Explanation of the various products and their particular application to mining will be given on request to the Dixon company.

DU PONT PRIZE PHOTOGRAPH CONTEST

To increase the interest in the Du Pont products, and to secure suitable photographs to illustrate the advertising and publicity of their various companies the Du Pont American Industries offer \$500 in prizes for the 50 best photographs. The prizes are as follows:

First prize, \$100; second prize, \$50; third prizes, two of \$25; fourth prizes, fourteen of \$10; and fifth prizes, thirty-two of \$5.

The photographs are to illustrate the following subjects, and be submitted before September 1, 1918: Agricultural uses of explosives; fabrikoil (artificial leather); industrial uses of explosives; painting; trapshooting and hunting; miscellaneous. Any subjects illustrating the use of any Du Pont products, will be given equal consideration. Some of the conditions of the contest are: No employees of the Du Pont American Industries are eligible; each photograph, to be eligible for a prize, must be accompanied by the negative (film or plate); on the back of each photograph submitted must be plainly written the name and address of the contestant, the subject illustrated, the place where the photograph was taken, and any other helpful data; the number of photographs that can be submitted by any one contestant is unlimited, nor is there any limit to the number of prizes that can be won by any contestant; all photographs submitted, whether awarded prizes or not, are to become the property of the Du Pont American Industries; all photographs submitted will be judged by a committee to be appointed by the director of advertising of the Du Pont American Industries, the prizes to be awarded not later than September 15, 1918; the Du Pont photograph contest will close on September 1, 1918; no photographs postmarked at Wilmington, Delaware, later than September 1, 1918, will be accepted in this contest; each contestant must fill out and mail an entry blank to the advertising division of the Du Pont company, Wilmington, Delaware, with the first photographs submitted, or the photographs will not be accepted in the contest; all photographs entered in this contest must be plainly marked 'Photograph Contest' and mailed to the Advertising Division of the Du Pont company, Wilmington, Delaware, full postage prepaid.

The Du Pont products are used or sold in almost every business house and home in this country. Probably in your own home, or in the neighborhood, or at least where you work, there is a good chance to obtain a prize-winning photograph. To the amateur, it may be said that he should see that his photograph has good contrast, and is clear and sharp in focus. If possible, it should be at least 3 by 5 inches in size. Experience prompts the suggestion when the photograph is taken, make a black and white, glossy finish print. Do not try too hard to get an unusual effect. This is not an art contest. These photographs are to be used for advertising purposes, and if they show clearly and effectively what they are supposed to represent, and will reproduce well, they will have a good chance of winning a prize. Any one desiring to enter should notify the Du Pont company, and an entry blank will be furnished.

HURRAH for the Third Liberty Loan! Not only has it been handsomely over-subscribed, but the number of citizens contributing is 17,000,000, as against 10,000,000 to the second and 4,500,000 to the first loan.

IN an evening newspaper we read that "a hopeful sign in connection with local golf is the large number of young athletes of both sexes who are now playing the game." We differ: the male athletes that are young and that are devoting themselves to golf at this time are *not* "playing the game." They are slackers that are renegades to the true spirit of sport and a disgrace to the royal and ancient game of golf.

DURING the eight months preceding March the export of copper was 665,000,000 pounds valued at \$196,000,000, as compared with 592,000,000 pounds worth \$162,000,000 in the corresponding period of the previous year. On the other hand, the imports of copper in the same eight months amounted to 242,000,000, as against 212,000,000 last year and 167,000,000 the year before. Most of this came from Chile and Peru, the Mexican shipments having decreased, while those from Spain have ceased entirely.

IMPORTATION of lead has been restricted by the Government in order to save tonnage, both by land and sea. Even Mexican and Canadian shipments are under embargo, owing to railroad congestion, but it is expected that Mexican lead will be admitted again shortly for the sake of its silver contents. In the first eight months of the present fiscal year 114,000,000 pounds of lead has been imported, as against 41,000,000 and 64,000,000 in the corresponding period of the two preceding years. During the eight months 97,000,000 pounds came from Mexico alone, leaving only 17,000,000 to be credited to all other foreign sources of supply.

CESSATION of imports of tin from the Dutch East Indies has caused the price of that metal to rise in this country. We produce no tin, our supply coming largely from the islands of Banka and Billiton, belonging to Holland, and from Bolivia. The seizure of Dutch vessels is the immediate cause of our shortage of tin, but it is probable that our loss in one direction will be corrected in the opposite direction, for Great Britain, it is to be

presumed, will arrange for the release of some of her supply, which comes from Cornwall, Nigeria, Australia, South Africa, and the Malay States. A large part of the Bolivian output has been coming to this country since the American Smelting & Refining Company built a smelter in New Jersey, but lack of shipping hinders importation at this time. Incidentally we may mention one of the substitutions incited by the exigencies of the War. The packing of jam for the British army is done no longer in tin-plate, that is, 'canned'; it is placed in a container made of cardboard, of which 3,000,000 are used weekly in the manufacture of jam.

NEWSPAPER control is a powerful weapon in a democracy. It is one easy to abuse. Mr. Hearst has acquired the Chicago 'Herald,' thereby widening the streak of yellow journalism that besmirches this country. It is a great pity—to put it mildly—that a man of such character should, by the control of a dozen newspapers, exercise so great an influence, for, unfortunately the printed word is taken seriously, particularly by the uneducated. A similar condition exists in England. Lord Northcliffe is a man of more principle than Hearst, of course, but he also has abused the power gained by his control of 'The Times' and a number of other newspapers. If the world is to be made safe for democracy, it must recognize the danger of unscrupulous newspaper-ownership. That might be done by restricting ownership to one paper.

NO longer need we speak of 'they'; it is 'we' that are fighting; not 'the' Allies but 'our' Allies are withstanding the German onslaught; it is 'our' line that is being held by the British, French, Belgian, and American armies, just as surely as if it were upon American soil, on the slopes of the Alleghanies or on the plains of Nebraska. Moreover 'our boys,' under the star-spangled banner, are in the thick of it, holding up their end in just the way we expected. After weeks of newspaper exaggeration of minor trench-raids and patrol-skirmishes it is good to read of real battles in which American soldiers have won the admiration of the French and British by their valor and skill. They showed "the greatest audacity and a fine spirit of sacrifice," said a French general, when conferring decorations on 117 men of the 104th (Massachusetts) regiment, which bore the brunt of the German attack in the forest of Apremont

on April 12. Mr. Lloyd George also has said, enthusiastically, that "the American troops are first-class fighting material, full of courage and resource, and very keen." Of course they are. We are proud of them.

AS a side-light on the enactment of the Pittman silver bill we print on another page an excerpt from the Congressional Record giving part of the debate in the House. We may dismiss the notion that it was passed as a measure of relief for the silver miners. Neither Senator Pittman nor any of his colleagues labored under a misapprehension regarding that. It was an urgent case of war legislation, put upon the statute books by request of the President, following the earnest solicitation of Great Britain to avert trouble in India. The German is not absent even there; his insinuations reach the ears of local potentates, and arouse dormant hatreds and suspicions. Large trade balances remained unsettled; the coin to satisfy them had not come forward, and the thought that the Indian was being used and cheated, subtly put into the Oriental brain, would be like setting fire to tow. It is easy to release this store of silver, now serving a minor financial purpose, which is measured by the relatively small sum of approximately \$3.50 per capita, and convert the certificates it represents into a revolving fund for buying more metal from the miners. It is firing silver ammunition to destroy the German propaganda in America, which reminds one of the old Scotch superstition that the silver bullet never misses the mark. Incidentally it contributes to the welfare of Utah, Nevada, and a few other States in the Union. The market quotations on silver still show a considerable discrepancy, in spite of the fact that the Pittman bill became law by signature of the President on April 23. These represent prices fixed for business in London, and have nothing to do with the price actually obtainable in this country. On the other hand, the time consumed in securing settlement from the United States mints is such that many producers are willing to discount the fixed Government valuation in order to convert their bullion into ready cash. Certificates of reputable refiners, therefore, are negotiated through the banks, at a slight reduction from the standard dollar rate per ounce.

GOLD, its production and its economic status, is the subject of an article by Mr. Hennen Jennings appearing in this issue. Anything that Mr. Jennings writes is interesting because he is known to be an observant and sagacious engineer, with an experience enriched by travel and study in many countries. In his article he reviews the functions performed by gold in the business of the world, he gives a summary of the latest statistical information concerning output, he furnishes data on the increasing cost of production, and then discusses the gold standard in relation to the debts being incurred by the principal belligerent countries, thus affording the reader a valuable résumé of basic conditions. The comparative newness of big mining operations for gold is a good point, as illustrating the stimulating effect of modern science when applied to an

ancient art. The Allies today produce 91.3% of the world's gold, whereas the output from the Enemy countries constitutes only 0.6%. This surely should prove a potent factor in the adjustment of international obligations when the War is ended. The estimate of the world's production for 1917 given by Mr. Jennings is \$430,000,000, as against \$414,000,000, the figures of our guess as given last week, and it will be noted that Mr. Jennings' forecasts of future production in Australasia, Canada, and Rhodesia, for example, are more cheerful than our own, because, we presume, our distinguished friend is averse from being too positive in matters concerning which full information is unavailable. One small point to which we demur is the statement that the first stamp-mill on the Mother Lode of California was started in 1852, for we happen to know that the first machine of this kind was a sectional 10-stamp mill brought by James Rickard, a Cornish mine-captain, to Coulterville on the Mariposa grant in 1850, to test a group of gold mines placed under option to John Taylor & Sons by General John C. Fremont. To say this is like taking coke to Connellsville, for Mr. Jennings is now honorably connected with mining on this same Mariposa grant. Turning to a more important matter, we note the striking simile used by Mr. Jennings in his closing paragraphs, in which he brings out the fact that gold is a storage-cell of human energy, that its value is founded upon the labor, mental and manual, expended in extracting it from the ground. We also like his view that the rich are merely the defectors of such energy. When they die they leave it behind to be used by their successors. Therefore, in an intelligent community it should be the aim to deflect this energy to the most fruitful purpose.

Spoiling the War Minerals Bill

Announcement is made of the passage of the mineral-control bill by the House in a materially altered form. The fundamental reason for this measure, regardless of the wider ambition of some of its sponsors, was to provide assurance of mineral supplies that for the most part are needed in relatively small quantities, but are vital, nevertheless, for the successful prosecution of the War. By the action of the House of Representatives much of the stimulative value of the bill apparently has been eliminated. The Executive is shorn of authority to fix prices, and the fund available for subventioning approved enterprises is reduced to \$10,000,000, being one-fifth of the amount originally proposed. Even the larger sum seemed to us inadequate for carrying out the purpose of the measure in the most useful way, but we supposed it would be comparatively easy to obtain further appropriations as the need was shown. To reduce the available funds to \$10,000,000 and at the same time to withdraw the power of the President's administrative appointees to fix prices is to destroy the possibility of individual initiative in many hundreds of cases where men of limited means are willing to risk their savings in small mine that men of big business could not afford to operate. The

production of tungsten, chrome, molybdenum, antimony, and manganese, for example, does not constitute the class of enterprise that commonly attracts large capital. The Government will be short of its requirements in these substances unless the small miner is directly aided and protected in the manner proposed in the bill as originally introduced. The mining of pyrite in this country has been retarded in the past because the Spanish mines, capable of being operated on a large scale and at low cost in a country where small wages prevail, and containing copper and a minor amount of the precious metals to be won from the cinder as a by-product, offered an almost overwhelming competition against the exploiters of Eastern deposits where the ore was free enough from arsenic to make good sulphuric acid. These deposits must be protected by guarantees for a period at a fixed price, or must be financed by the Government itself, to warrant the use of the capital needed for development and beneficiation. Estimates by those best informed indicate a requirement of 9,000,000 tons of sulphuric acid this year, whereas there is sulphur available for making only 7,500,000, leaving a shortage of 1,500,000. In spite of a curtailment of the chrome ore set aside for refractories to about 12,000 tons, and of a reduction of the amount of chrome for use in the chemical industries from 40,000 to 20,000 tons, the urgent requirements for producing ferro-chrome swell the demand this year to about 150,000 tons, according to a forecast by the War Industries Board. Domestic production last year was only 40,000 tons, and without suitable guarantees it is not to be expected that small investors will be able to risk their money in the production of a mineral that exists habitually in small, erratic, and widely scattered deposits. It is just because most of the products specified in this bill are found in small quantities, and constitute a basis for mining that is highly speculative as compared with copper, lead, and zinc, for example, that this market has been dominated to a large extent by brokers. The producer usually has not been able to deal with the actual consumer. The middleman seemed necessitated, and, as usual in such cases, the field of the legitimate commission merchant has been invaded to a large extent by sharpers. Producers of the minor metals and minerals have been so victimized by disreputable brokers that the Government must extinguish the breed if a great increase of production in these substances is to be realized. That means direct contract with the miners, and facilities for assisting in financing operations of merit. It must be noted that a considerable proportion of the middlemen who deal in these subsidiary products are Germans and German sympathizers. A persistent policy on their part has been to keep negotiations with prospective producers dangling as long as possible, and to offer attractive prices so limited by conditions of time and other details imperiling the shipper as to check the output during the War and to cause financial losses that would discourage vigorous development. Congress is doing its best to facilitate the efforts of our country to grapple successfully with the grave issues raised by the War, and it has doubtless acted in

the light of what seemed intelligent advice in emasculating the bill, as now reported by the Associated Press, but the result would be to leave these special industries exposed to the sinister influences that have dominated them in the past. We have but to recall how the Nation was tricked by the German chemists into wasting our precious opportunities to become independent of foreign resources in the matter of fixed nitrogen, to realize the importance of defeating the apparent purpose to limit the production of the vitally needed materials of War that this bill was intended to facilitate. We look to the Senate to re-instate the authority to fix prices and to make contracts for a period of at least two years on a basis commensurate with profitable operation, when the bill comes before it for consideration. We understand that the President, as well as the Secretaries of War and the Navy, already possess the right to commandeer these or any other minerals, but the prices are arranged by the War Industries Board through agreement with the producers. In this way prices may be established by the President, but only on the recommendation of the price-fixing committee, after an investigation has been made by the Federal Trade Commission. This is a long circuitous method of approximating the end that is attainable directly and swiftly by a single administrator under the pending bill. It involves the persistence of red-tape which has already defeated so many well-meant efforts of Government officials. Multiplicity of committees sharing responsibility in such a case introduces delay, and affords opportunity for interested parties to exert an influence through plausible objections. Whether done with deliberate purpose to limit our efficiency, or merely for personal pecuniary advantage, the result is the same; it slows us down in producing the materials needed in the War. Incidentally this, more than any other measure yet enacted, was looked upon as offering the small miner a chance to serve his country and obtain a little profit at the same time. The skill to prospect successfully and to produce minerals economically is a valuable national asset worthy of encouragement and reward. Mutilated as the bill appears to have been by the House of Representatives, the advantages it possessed as a democratic measure have been sacrificed, and its effectiveness as a stimulant to production has been seriously impaired.

Incorrigible Mexico

"What can be done to create friendly relations with Mexico?" writes an eastern correspondent. Can anyone answer that question? Our Government has tried to help Mexico; it has coddled and petted Mexico through six long years of turmoil and misrule; it has borne patiently with murder and rapine and insult, in a sincere effort to bring about reforms that should in the end restore political and industrial stability; but it has failed. Mexico today is a centre of political corruption, shamelessly submitting to be used as a base for German activity against the welfare of this country, persisting in the destruction of American interests in her mines and farms, which is accomplished under cover of decrees

that give a varnish of legality to the proceedings. Mexico displays contempt for our nationals and for our Government; it is clear that she construes our long forbearance as an indication of impotence. We have hurled 'ultimatum' after 'ultimatum,' only to follow gentler courses than had been threatened, until her people laugh and refuse to take us seriously. They talk of the heroic Teuton, and call the American craven. It is a pity to have to confess it, but such is the fact. Our Government has dealt gently with them and they translate our kindness into cowardice. When Carranza wrote his first letter to President Wilson several years ago he was a fugitive after defeat in Coahuila, domiciled in Sonora, where he was trying to bluff the State government into accepting his leadership. Villa meanwhile was conquering Chihuahua, and in a half-hearted way was recognizing the long-whiskered chief who claimed to be the defender of the Constitution that he later violated and overthrew. An American had been taken prisoner in the Sierra; our State Department demanded Villa to surrender him; Villa, thinking to be clever, referred our Government to Carranza. That was the first opportunity accorded Carranza to display his diplomatic astuteness. He wrote a letter, which was insolent and petty, quibbling over the division of authority as between himself and Villa, and pointing out that the boundary line in the Sierra was not well-defined. Therefore, he pleaded that the matter of jurisdiction was uncertain, but an investigation would be made, and so on. The American disappeared from sight, the case was settled by delay, and Carranza had scored his first diplomatic triumph. From that time forth lofty impudence has been the characteristic attitude of Carranza toward this country, its President, and its people. We have accepted it, our ultimatums never reached finality, our invasion at Vera Cruz ended in evacuation at the command of Carranza; our invasion of Chihuahua in quest of the evasive Villa, who was sheltered by every Carrancista, made us a joke and a by-word, and ended in withdrawal with nothing accomplished.

It is time that we redeemed the errors of our good nature by no longer suffering our desire for the welfare of Mexico to hold our hand now that she has become a menace to us in the great War that we must win. Carranza understands force. He knew the meaning of it when it overcame him in Coahuila; he will understand an ultimatum from the United States at this time, for we have ceased being pacifists; we are in earnest now to save the world from the Hun, and the voice of President Wilson to a recalcitrant Mexico will possess an unfamiliar harshness that will command obedience. We have had to suspend telephonic communication across the border, because of the nest of German spies using it to obtain information to send to the intelligence department of the Kaiser; we have seen a German raider outfitted openly in a Mexican port; we have seen a great American smelting enterprise forced out of business until it compromised with the exactions of local officials, while its Teutonic rivals flourish in the same so-called republic; we have seen our efforts to enter into a reciprocity treaty

waved aside contemptuously; we see oil production threatened by impositions that are meant to hamper us and our Allies, and, if complied with, to make us seem such easy game as to win adherents to the Government through the opportunities offered for graft. Meanwhile Mexico is bankrupt, her citizens are resisting the pet measures of Carranza because his administration has been discredited by corruption; the people in the cities are famine-stricken; the actual control of the Government is limited to the few rosaries of towns along the railroads; but the spirit of genuine reform is present in the nation at large, and all they need is a leader. The surest way to call forth the strong man is to send Carranza a demand for compliance with the old unabrogated treaties, and to follow it with a demonstration that will leave no doubt of the purpose of America to end this nonsense in Mexico. We desire the friendship of Mexico, but we do not possess it. We have given Carranza years of opportunity for reform in his attitude, but his enmity grows deeper and more dangerous. He has even shut off his newspapers from this country so that we may less readily gain information of the schemes afoot in aid of our arch enemy. We cannot afford to permit a neighbor to threaten our well-being. If Mexico will not accept our friendship when offered with the olive branch, she may appreciate it better if offered with the last argument in diplomacy.

We must, however, keep in mind that our country is pledged to stamp out imperialism, that our President has promised to eliminate it utterly from the democratized world that is to arise from the existing conflict, that we are on our honor to establish the principle of self-determination as another of the rights of man. This will govern us in our relations with Mexico, with Central and South America, but it is not too much to pledge again to our Allies and to all the World our word that we will not disregard our high mission by moving our border southward, neither by absorbing more Porto Ricos, nor by conniving at the rupture of another Colombia. We stand convicted of imperialism in the past; in this hour of the trial of democracy and freedom, we must confess that we have given our neighbors in the Western Hemisphere cause to hold us under suspicion. Nevertheless, no one is so blind or so prejudiced as not to recognize the restraint of a benevolent giant in our dealing with Mexico while she was passing through the paroxysms of anarchy. That was hard to endure, in the face of the murders and the shameless atrocities committed against American men and women, and our forbearance under these provocations was not only misjudged by Mexico but by the German militarists. They thought, not that we were "too proud to fight," but too pusillanimous to fight. Our generosity to Mexico helped to encourage the German in his atrocities, which finally led to war. We will not violate our pledges nor rob Mexico of a single square mile of territory, but she has trifled too far with our tolerance by harboring German plotters against our safety. A deep significance lay in Secretary McAdoo's choice of El Paso as the place for announcing at a public address that "the United States has gone to the very limit in dealing with Mexico."

DISCUSSION

Chlorides in Flotation

The Editor:

Sir—In your issue of March 23 we have noticed an editorial regarding the use of chlorides in testing ores by flotation as conducted by M. H. Thornberry and H. T. Mann of the Missouri School of Mines, the results of which were published in 'Metallurgical & Chemical Engineering'.

Messrs. Thornberry and Mann deserve much credit for their good work, but we question their conclusion that chlorides are distinctly unfavorable to flotation, even when used in conjunction with some other flotative agent such as oil. In testing ores by flotation at the School of Mines laboratories of the University of Idaho, which work is in co-operation with the U. S. Bureau of Mines, it has been found that certain alkaline chlorides and carbonates are beneficial in floating the sulphides of some ores, whereas the opposite effect has been noted on other similar ores from a different mining district. The point that we wish to bring out is that each ore may require a somewhat different flotative mixture, and that the effect of a certain reagent (such as chlorides) on one ore may be different on some other ore. We do not question the results obtained by Messrs. Thornberry and Mann, but wonder whether it is good policy to make such a sweeping statement without first having tested, under like conditions, ores from several mining districts throughout the country. Some millmen who are testing their ores for the flotation process, might conclude, after reading the articles by Messrs. Thornberry and Mann, that chlorides are detrimental to flotation and would, therefore, not consider their use (chlorides) alone as a flotative agent, or in combination with oil or some other reagent. In other words, there is often danger in drawing conclusions from flotation tests in that the reader is apt to be deterred from trying other possibilities.

C. A. WRIGHT.

JAMES G. PARNELEE.

Professional Peonage

The Editor:

Sir—I have read the letter appearing in your issue of April 20 with sympathetic interest.

It is but one of the few stray bubbles that rise occasionally to the top of the long-watched simmering pot so industriously stoked by short-sighted employers. There will come a time when the pot will boil over and the burnt employers will break forth into lamentations about the "tyranny" and the "despotic attitude" of the associated engineers. These employers have acquired a large

vocabulary of abusive terms in their losing fight with organized labor. Organized labor did not spring forth armed and ready like Athene from the brow of Jove nor was it conjured up by selfish agitators for their own vile purposes, but it was the net product of the greed and short-sighted policy of the employers. History has a way of repeating itself and it is to be expected that the engineers will finally be driven into some sort of an organization whose main purpose will be to secure for its members a just return for the services they render. When that day comes the short-sighted folly of the employers will be definitely manifested. For the engineer is singularly unselfish in his work. He strives constantly to strengthen his capability that he may render better service. His organizations have for their object the dissemination of technical information to the end that the members may be better able to serve their employers. He is actuated by the same spirit that pervades the men of science. He has always aligned himself on the side of his employers and has fought their battles without thought of bettering his own material conditions. And in what measure has the employer responded to this unselfish attitude on the part of the engineer? By reducing him to "professional peonage"!

In your columns under the caption 'Positions Vacant,' I note advertisements soliciting the services of 'mining engineers' at the princely salary of \$125 per month. For technical men, mind you! In the Globe district of Arizona, the muckers receive from \$140 to \$150 per month. One of the employers in this district told me that the qualifications most desired in the mucker are "a strong back and a weak mind." Do not judge from this that the mucker, individually, surpasses the engineer in the esteem of the employer, nor that the employer pays this wage to the mucker out of the largeness of his heart or the generosity of his soul. He has been literally kicked into it. His yielding in this matter is paralleled in the recalcitrant attitude of the young scamp who is dragged into the kitchen by the irate father by the scruff of his neck as a preliminary to the administration of a sound licking.

Unless it is native within him, the engineer emerges from college with but little capacity for dealing with matters of business. His entire attention and ambition is centred upon technical perfection. He is, in a business sense, primarily a job-seeker and a salary-getter. He usually has little ambition to acquire wealth, and less opportunity. He sometimes makes a break to get into the employer class, secures an option on a good property and, more or less timidly, enters the terra incognita of

promotion unwise to the fact that, as a professional man, he is intellectually and temperamentally unfitted for the task. He wriggles hopelessly for a time, goes broke, and proceeds anxiously to scan the column headed 'Positions Vacant.' No doubt, the wise business-man who receives his application has several good hearty laughs at the many blundering departures from the fine art of salesmanship. He may be employed in spite of them, however, but the business-man has been impressed with the idea that it would be a waste of good money to pay this fellow a decent wage, since the applicant is evidently "up against it."

I have a daughter approaching the marriageable age. I am obsessed by a dread lest at some time some bright capable mining engineer persuades her to go with him to the altar, where the minister will pronounce the fatal words condemning her to a life of poverty and anxiety. Before the exigency arrives, I am advising her to demand the union card.

ANOTHER ENGINEER.

Phoenix, Arizona, April 25.

The Supply of Pyrite

The Editor:

Sir—There has been a great deal of agitation on the subject of minerals and ores of various kinds, and in the 'Engineering and Mining Journal' of April 6, Dr. W. H. Nichols states, in referring to the available supply of pyrite for the manufacturing of sulphuric acid, that his company, the Nichols Chemical of New York, has arrived at the conclusion, after examining every known deposit on the Eastern coast, that it will be necessary to go abroad for the lacking quantity. In the same issue, the statistician of the U. S. Geological Survey states that among the enumerated minerals and ores required and available, the productive capacity of pyrite in this country is 33%.

For many years I have been actively associated with copper mines on the Pacific coast, especially in California, and, as we all know, there is hardly a copper mine which with depth, and in cases very close to the surface, is not capable of producing massive sulphide ores that will average at least 40% sulphur, which ores have very little zinc, arsenic, and selenium; and even were it true that in some cases these objectionable elements are present, catalytic acid-making, the present methods of clarifying the roaster-gases is such that almost any massive sulphide of the pyritic type can be used. For chamber acid this is not so necessary, and of this material California has an almost unlimited quantity.

If pyritic ores are so necessary for the manufacturing of supplies necessary for the conduct of the War, why have not the resources of the mines of California been investigated? If pyrite can be imported from Spain, and other foreign sources, it must be done in ships, and as there is less likelihood of these being destroyed by journeying from the Pacific coast to the Eastern coast (due to the under-sea boats of the Enemy) there surely is all the opportunity for supplying a great deal of the

tonnage required should a market be given for the sulphur contained at the market price of from 26 to 30c. per unit as given in your metal quotations, to which will be added the copper and small values in gold and silver. Figuring these on the basis of an ore that I have tried to market, and absolutely failed to sell to the smelters in California, to any of the acid works of any consequence, and to the only smelting plant in Nevada, which requires this material (massive sulphide ore), I have been unable to market in any sense whatever an ore that at the present price of copper and silver makes it worth \$15.60 per ton. The ore will average 40% sulphur and a greater part will contain 45%. It contains no zinc, but 3.5% copper, with 2.3 oz. silver, 0.03 to 0.05 oz. gold, and only 4% silica. Deducting the usual metallurgical losses, and assuming a selling price of 25c. per unit for the sulphur, this ore is worth \$26.35. Assuming a freight-rate from the mine to San Francisco of \$1.35 and water carriage to the Eastern coast of \$8, and a smelter treatment for the cinder or calcine of \$2.50 per ton, there is still \$11.85 per ton for mining and for profit.

I have the correspondence bearing on this subject, should it be required to substantiate the statement *that there is not a market on the Pacific coast for this class of ore*, owing to the quantity offered from the mines owned by the smelting companies. I shall be glad to submit the letters for publication.

I know of other mines and excellent prospects, as do all the well-informed miners who are familiar with the copper resources of California, which can and will produce about all the tonnage that railways and ships can carry should you or some other public-spirited citizen agitate the subject and call the War Minerals Committee's attention to what you have at home, and put to use and to work the resources in your State.

What is needed is a central exchange in the shape of a crushing and sampling mill on the water-front, with the ability to purchase these ores as received, store the same, and load in bunkers for ships seeking a cargo.

When in the management of one of the large sulphide mines just at the beginning of the War, I made such an arrangement to ship to the Tacoma smelter, and the same location and arrangement are available again.

Should you make inquiry from the miners of California, and should a market as mentioned be established, I will guarantee to show a tonnage of acid-making material, other than the pyrrhotite ores in the southern part of the State, that will go largely to relieve the wants of the Eastern acid-makers.

The lower grades, so far as metals are concerned, should be considered, and I do not hesitate to say that thirty to fifty thousand tons per month can immediately be furnished, provided ships are available, the Panama Canal route, of course, to be chosen. Should there not be the smelting capacity in the East for the calcine, this can readily be supplied, as I did for the Peyton Chemical Company.

E. H. WEDEKIND.

Reno, Nevada, April 24.

HYDRAULIC MINING, WITH MONITOR AND ELEVATOR, IN ALASKA

The Gold Industry and the Gold Standard

By HENNEN JENNINGS

Gold attracted the attention of primitive man by its color, lustre, and indestructibility. The earliest mining and metallurgical operations of which traces remain were those in Egypt that dealt with the ores of gold. From pictorial rock-carvings in Upper Egypt, as also from Egyptian hieroglyphics, it is found that the search, desire, and use of gold extended back some 3000 to 4000 years before the Christian era.

Starting with use as an ornament, gold soon became the trading counter and has been an emblem of value to the human race as far back as history extends. Appreciation of the value of gold has been maintained through the centuries by the difficulties connected with obtaining the metal.

With early primitive methods, only the gold most abundant and easily worked and visible was first sought and this was found principally in alluvial deposits, but as knowledge, mechanical skill, tools and appliances were developed by the human race gold mining was extended to more difficult alluvial, vein, and lode deposits.

Gold, when it became the counter of trade and a measure of possession, was the most eagerly sought of all possessions, and thus it became the pioneer and stimulant to mining, metallurgy, and chemistry. The search for this precious metal became so intense that the alchemists sought its transmutation from other metals, which, though they failed to accomplish, won them other knowledge and gave birth to chemistry.

The trading value of gold has been stabilized by history in that no superabundance was ever obtainable and it has always been necessary to expend labor and intelligence to an extent largely commensurate with the bartering value of the gold obtained.

Accurate records do not exist of the actual outputs of

gold in early times, but certainly they must have been small from a modern standpoint. Great outputs of gold, as of all other metals, are a matter of recent times. It has been officially estimated that the world production of gold since the discovery of America, in 1492, to the end of 1916, a period of 424 years, was \$16,601,641,319. The output since 1894, a period of 23 years, was approximately \$8,500,000,000, or slightly more than 50% of the total mined in 424 years. The average yearly production up to 1894 was \$19,107,644, while since 1894 to date it has averaged \$369,565,217 per year.

The gold available as a reserve in 1894 has been estimated at \$3,965,900,000. The loss of gold and its absorption in the arts and manufacture of jewelry accounts for the differences between the amount produced and the amount on hand. The amount of gold used in the arts has increased since 1894, and of late years it has been between \$50,000,000 and \$100,000,000 per annum. Estimating the consumption and loss of gold since 1894 at \$2,000,000,000 the amount of gold at present in reserve may be roughly estimated at \$10,500,000,000.

The concentration and portability of this wealth can be appreciated by converting it into tons weight, for the total tonnage of the entire gold reserve of the world does not amount to over 17,000 tons and it could be easily transported around the world in a large steamship.

Gold, as also silver, has advantages as money-counter owing to large value in small volume, ease of transportation, divisibility without loss, beauty, brilliant lustre, great durability, ease with which they can be guarded, and the difficulty of counterfeiting.

The function of the various mints of the world is to give guarantee of the weight and fineness of the gold they coin. The United States dollar contains 23.22 grains of gold and 2.58 grains of alloy, making a total weight of

*By courtesy of the Director of the U. S. Bureau of Mines.

25.8 grains, or 1.677 grammes, and its fineness is 900. Gold coins of all nations, under normal conditions, are exchangeable on the basis of their content of fine gold.

A broad outlook on modern mining and a study of the output curves of metals since the discovery of gold in this country, in 1849, in Australia, in 1851, and in the Transvaal, in 1886, indicates that big mining is surprisingly modern and that great outputs of other metals have been pioneered by gold. Until the last few years, gold outputs have shown a parallelism with those of coal, iron, and copper, with the growth of railways, and the deposits in our banks. It would seem that the outputs of coal during the last 18 or 20 years; of iron, in 15 years; of copper, in 13; and of petroleum, in 11 years, were greater in aggregate than the output of these products for all previous history.

The mineral outputs of modern times have been rendered possible only by the advance made in invention, engineering, chemistry, and business organization. Even so, it would now appear that the gold output of the world has about reached its zenith, and is giving indications of future decline, as shown by the returns for the past ten years, as under:

1908\$442,476,900	1913\$459,941,100
1909454,059,100	1914455,705,000
1910455,239,100	1915468,724,918
1911461,939,700	1916457,006,045
1912466,136,100	1917430,000,000

The extreme variation of output during this period is not great, but on the basis of the estimate for 1917, a drop of 6% is seen from the previous year.

The gold production table appended gives the gold returns from all countries of the world from 1912 to 1916, inclusive, with relative percentages for the pre-war year 1913. See Table A. The percentages given are based on the 1913 production with normal mining conditions, when the Allies produced 91.3%, the Central Powers 0.6%, and the neutral countries 8.1%.

The table shows that gold has been mined in about 60 different countries, and in all the continents of the world. It has been found in the oldest rocks and in almost all subsequent geological formations. Traces of gold have been proved to exist in sea-water, so the distribution of gold is most widely spread, but never in quantity compared with other metals. Exceptional occurrence and favorable natural and commercial conditions are required for its profitable extraction.

The relative production of gold from all countries is given in percentages for the pre-war year 1913, and on a war basis they can be classified as, Allies, Central Powers, and Neutrals, with percentages as follows: Allies, 91.3; Central Powers, 0.6; Neutrals, 8.1. Of the Allies, it is seen that Great Britain, with her dominions and dependencies, produced 62.6%; United States 19.3%; and Russia 5.8%.

The main gold-producers of the world rank in order thus: Transvaal, United States, Australasia, Russia, Canada, and Rhodesia.

Australasia's gold output from 1851 to 1903 amounted

to approximately \$2,060,000,000. The output in 1903 was about \$87,000,000, but since then production has decreased gradually until in 1916 it amounted to only about \$39,000,000, or 45% of the production in 1903. There is at present no indication of any large increase of output in the future.

The Canadian gold output was very small in 1891, but mounted rapidly until 1900, when the Yukon placer workings seemed to have reached their maximum; in that year the Canadian districts produced \$28,000,000. Since 1900 there has been a fluctuating downward tendency. The years 1915 and 1916, however, show some increase; the production for 1915 being \$18,977,901 and that for 1916, \$19,234,976. War conditions are unfavorable for exploitation or new discovery. The extent of territory and natural conditions are such, however, as to give hope of future greater outputs.

Russia's gold statistics are open to doubt. It would appear that gold has been worked in the Ural district since 1820 and that in the last 12 or 13 years outputs have varied from \$35,000,000 to \$22,000,000 a year. Some engineers express the belief that Siberia has greater possibilities for future discovery and exploitation of gold, as also of other metals, than all other regions in the world. At present, in view of war and industrial conditions, the prospect of large outputs of gold in the immediate future is uncertain.

Of the South American and Central American regions, Mexico is the most important. The revival of gold mining commenced with a small output in 1890, the maximum production being reached in 1911 with an output of \$29,200,000. Owing to the revolution in that country the output has dropped to \$7,690,707 in 1916, which was a million dollars increase over 1915. When the country is in better political and economical condition there is good ground for hoping for increased returns.

In other parts of Central and South America the outputs have not been large, but there yet remain large stretches of unexploited territory and abandoned properties that may be found profitable to work.

The following tabulated statement for the Transvaal is given in full, as it is the most complete record of gold-mining operations in the world. The yields, working costs, and dividends, from 1887 to 1916, a period of 30 years, have been obtained by sworn statements to both Boer and British governments. See Table B.

The total output for these 30 years was £492,198,901, or about \$2,300,000,000. The return for 1916 was £38,107,909, or about \$185,000,000, which was 40% of the world's output for that year. The dividends amounted to 24% for the whole period, but only 18.6% for the years 1915 and 1916.

There has been a great struggle to lower expenses, which have been reduced from 42 shillings to about 17s. per ton. The average yield has been downward, and fell from 49 to 26 shillings. It would seem that the Transvaal has reached its maximum output and is on the downgrade.

The gold mines of the Rand are greatly favored by the fact that coal is found in close proximity to the gold.

Table A. World's Production of Gold, 1912 to 1916, Inclusive

(Compiled from the reports of the Director of the Mint, U. S. Treasury Department)

HOISTING AND CRUSHING PLANT OF THE GELDENHUIS DEEP MINE, JOHANNESBURG

DREDGE ON THE ANCOBRA RIVER IN WEST AFRICA

Also native labor has been moderate in its demands, and outnumbers the white workers nearly 8 to 1, thus allowing skilled white men an opportunity for generous pay, which they have obtained.

The existence of gold in Rhodesia had been known for many years, but material gold returns only started in 1898, and have steadily increased until 1916, when the output amounted to over \$19,000,000. There was a falling off, however, in 1917, of nearly two million dollars. The total production from 1898 to 1917, inclusive, amounted to \$194,672,165. At the present time the output is depressed by labor and supply conditions, and although the territory for mining operations is vast, with still unknown possibilities, there have been no new discoveries of late.

The total production of gold in the United States has been given by the Director of the Mint as under:

From 1792 to 1847.....	\$ 24,537,000
From 1848 to 1872.....	1,204,750,000
From 1873 to 1916.....	2,599,670,200
Total	\$3,828,957,200

The yield up to 1847 was obtained from the Eastern coast; from 1848 to 1872, largely from the placer mining in the West; and from 1873 to date, by combination of placer and lode mining and recovery of gold at refineries.

Dredging for gold in the United States dates only from 1896, and since that date the production from this source has been estimated at \$120,103,117.

In 1916 the greatest amount of placer mining, including dredging, was done in Alaska, where over 60% of the gold was thus recovered, and in California, where 38% was recovered.

The yearly production of gold in the United States, by States, from 1914 to 1917, has been as shown by Table C.

Although there are enumerated in the foregoing table 23 States from which gold has been taken, the first seven in rank have produced 89.62% of the total for the United States in the past four years. These States, in order, are California, Colorado, Alaska, Nevada, South Dakota, Arizona, and Montana.

The placer-mining operations of the country for 1916 produced about one-fourth of the gold output of this country, and of that one-fourth 56% came from dredging.

All the gold-mining corporations in the United States do not make public their yields, costs, or profits, as is the case in the Transvaal. Our Government does not make demand for such information. Some of the largest and best managed, however, give most complete and generous information, which can be found in the transactions of mining societies, mining journals, and handbooks. There would appear to be no reason for secrecy in gold-mining returns, as it is the one business in the world that does not face competition in marketing its product.

The richest and most easily accessible placer deposits in the United States, as elsewhere, have long since been worked out. Alaska is an exception in that the discovery

of placer gold there is of comparatively recent date and guarded by great climatic difficulties.

Placer mining on a large scale started in this country with the discovery of gold in California in 1848. The appliances and methods used were, first, the gold pan, followed by the rocker, long-tom, and short sluice-box, and subsequently by diverting water, shoveling, and washing gravel into long sluices and working on a large scale; then drift-mining, hydraulicking, and dredging.

It has been estimated that an ordinary pan holds about 20 pounds and that 45 to 100 pans per day is a good day's work. With a rocker, two cubic yards, or, say, 3 tons, is a good day's work. The cost of sluice-mining depends on the character of the material, amount of water, grade of the surface, and climate, but it may be said to vary from 20 cents to a dollar per yard for temperate climates.

In Alaska, gravel is subject to a preparative cost for thawing, amounting to 20 cents or more per cubic yard. Drifting, that is, underground mining of a thin layer of gravel and the bedrock adjacent, varies in cost from one to three dollars per cubic yard, and in Alaska as high as from four to five dollars.

Hydraulic mining, that is, the concentration of water under great pressure on banks of gravel, with provision for the removal of the washed material and recovery of the gold, varies from 2½ to 12 cents per cubic yard, and in Alaska up to 25 cents.

Dredging was instituted to work gravel deposits that could not be worked economically by other methods. It can be employed successfully only when a great number of favorable conditions exist, in which case remarkably low costs rule—from 4 to 9 cents in California, and up to 33c. or over in Alaska.

Lode or quartz mining in the United States and Alaska produces 75% of the output. For the world, the percentage is much greater. In South Africa practically all the output is from this source, and shafts as deep as 5000 ft. have been sunk on the Rand to develop the conglomerate deposits. In the United States lode mining has been conducted in a great variety of formations and in deposits varying from narrow veins of banded quartz with high yield per ton to great irregular masses of low-grade ore. The gold is often associated with tellurium and other metals. When pay-ore has given out at shallow or moderate depths, explorations to depths of 4700 ft., or more, have often been justified.

The treatment of the ores depends upon their richness and association with other minerals, and the processes for recovery mostly in use are the jaw and gyratory crushers, for the larger material, followed by stamp-mills, ball-mills, or rolls, for finer crushing, then plate amalgamation, by which in certain ores the greatest recovery is obtained; and concentration by vanners, shaking tables, or oil-flotation devices. The concentrates are treated by smelters, chlorination plants, or cyanide works. After stamping or amalgamation the whole pulp is often economically treated in bulk by the cyanide process.

The yields and costs vary in different districts and in different mines in each district. The greatest gold-producers have been mines of low or moderate yield per ton, but with great mass-occurrence and good conditions for economical working. The best example of such mining is the Homestake mine in South Dakota, which has been working since 1875, and has produced over \$147,000,000, the ore not averaging over \$4 per ton and costs ranging from 2½ to 3 dollars per ton with dividends of \$40,000,000 or 27% of the total output.

The records of the Alaska Treadwell group of mines, started in 1885, showed that up to June 1916 there had been crushed and treated 26,000,000 tons, yielding \$63,000,000, or \$2.37 per ton, and at a cost of \$1.42 per ton. The workings were extended to a depth of 2300 ft., some of them under the sea and the majority of the mines were flooded with water on April 21, 1917, and are now closed.

Lower yields and lower costs have been obtained by the Alaska Juneau and the Alaska Gold companies, which are only a few miles distant from the Alaska Treadwell mines. Working on a large scale has only been started at these mines recently. In 1916 the Alaska Gold Mines crushed nearly 2,000,000 tons, giving a yield of 97 cents and at reported costs of 73 cents. The Alaska Juneau's large mill has only recently been put into operation. It is anticipated that the yield and cost will be still lower. These are the lowest yields and costs known in gold mining. Hydro-electric power is used and all natural conditions are ideal for cheap working.

The Mother Lode in California, on which a 10-stamp mill was started in 1852, has been prospected or worked over an area of 125 miles, and has produced, according to estimates, over \$230,000,000 in gold. At two of the mines shafts have been sunk to vertical depths exceeding 4000 ft. Many mines, however, have been abandoned at moderate depths owing to failure to make them pay. The early returns per ton from the Lode were much higher than recently, for they do not average over \$4 per ton. Some abandoned mines have lately been opened up again and by hydro-electric power and better system of mining and management made to yield substantial profit. A notable case is that of the Plymouth Consolidated, in Amador county, re-opened after an idleness of 24 years, liberally equipped by capital and costs reduced to about \$3 per ton.

The North Star mine, in California, is a good illustration of a persistent but narrow vein of quartz, worked under good management, and being made to pay moderate profit for a long period. The mine was discovered in 1851, and since then to 1917 has produced 1,470,000 tons, yielding \$18,610,000, or an average yield of \$12.66 per ton. The total dividends have amounted to \$5,137,000 or about 35% of the yield. The returns for 1916 show a yield of \$10.42 per ton, with costs at \$6.26 per ton.

An example of rich yield, but with short life, is found in the case of the Goldfield Consolidated, in Nevada. Here, within eight or nine years \$50,000,000 has been taken out, but the yield has fallen from \$38.50 per ton in

1910 to \$7.52 in 1916. The cost must have been moderate on account of the magnitude of the lode.

The Portland mine, in Colorado, is another rich telluride mine. It has produced over \$10,000,000 with an average yield of \$27 per ton. The dividends, however, have not amounted to over 20%, as a great amount of development, dead work, costly mining and reduction have been necessary.

COST OF MINING. I was in California and Montana in December, 1917, where I had an opportunity of discussing with a number of operators, managers, and engineers the effect of the present economic conditions on the future output of gold, as also the proposed excess war-profits tax.

As labor and supplies go up, so must the cost of winning gold be increased, and the purchasing power of gold decreased. An index as to the decreasing purchasing power of gold is obtained by noting some of the increases in cost of supplies used in its recovery, some of which are given in the table below.

The advance in the cost of hydro-electric power has been small. The cost of coal and petroleum varies in different localities, but where necessary to use, is a serious item. The increase of costs is as follows:

	%
Labor	(about) 20
Steel (in California)	40 to 280
Manganese-steel (largely used in dredging)	130
Explosives	75
Quicksilver	93
Lumber	125
Machinery	75
Miscellaneous	10 to 200

Some companies with liberal margins between profit and loss can continue to work under present, or even much worse, conditions of labor and supply, but the excess war-profits tax may so operate as to induce them to curtail output. Some of the mines working on a narrow margin are being closed down gradually and others may be kept going for a time by reducing development work and up-keep of plant, and generally marking time while hoping for better conditions.

There has been a fear among operators that through the workings of the Priority Board there may be difficulty in obtaining transportation and other necessities to keep the mines in constant operation. The amount of tonnage that gold mining calls for from the railroad, where hydro-electric power is used, is very small, as the finished product is concentrated. It would also work a great hardship in the gold-mining industry to close down the works and compel the elderly and less efficient workers that have not already been tempted by higher wages to seek employment and remove their families from the district in which they have spent a large part of their lives.

EXCESS WAR-PROFITS TAX. This has been somewhat of a puzzle to many of the operators. The crux of the whole matter is how rightly to determine the rate per cent earned on the invested capital, that is, the result of dividing the net income by 1% of the capital. If the rate obtained is between 7 and 9%, there is no tax to be

paid. If above 10%, it progressively mounts until a taxation of 60% of all net profits can be imposed.

Difficulties at once arise in the interpretation of what is invested capital and what net income, and what are the legal deductions from ordinary income allowable before net income is ascertained. Invested capital may have an inflated showing in some system of accounts kept, while in others it may be over-conservative, in order to provide against the exhaustion of the mine.

The interpretation of the returns and the book-keeping of a gold-mining corporation becomes a most serious matter. It would seem from a reading of the law that a premium is placed on making a showing of high or inflated capitalization; also that large outputs and high yearly incomes are so penalized, especially with low

GOLD STANDARD. Almost all countries of the world have as their financial basis the legal standard of gold. Only a few retain the double standard of gold and silver—Italy alone among the combatants. Prior to the War, while there was freedom in trade and inter-communication between the different countries, the prices of various commodities were regulated both from within and without by the operation of the laws of supply, demand, and competition, stabilized by the intrinsic value of gold.

The debts of the principal belligerents at the time of their entering the War and those contracted since their entrance, as also an estimation of additional debts, are given in a rough manner in the table hereunder. They are sufficiently accurate, however, to illustrate the danger of the world's financial situation.

Table D. Debts of the Principal Belligerents

Allies	Pre-War	War	Total to Dec. 1917	Estimate of future annual expenditure
Great Britain	\$3,500,000,000	\$23,350,000,000	\$26,850,000,000	\$6,700,000,000
France	6,346,000,000	11,754,000,000	18,100,000,000	4,400,000,000
Russia	4,544,000,000	16,300,000,000	20,844,000,000	5,000,000,000
Italy	2,900,000,000	6,300,000,000	9,200,000,000	2,500,000,000
United States	1,200,000,000	7,000,000,000	8,200,000,000	14,000,000,000
Total	\$18,490,000,000	\$64,704,000,000	\$83,194,000,000	\$32,600,000,000
Central Powers				
Germany	\$5,000,000,000	\$20,650,000,000	\$25,650,000,000	\$6,000,000,000
Austria-Hungary	4,000,000,000	12,200,000,000	16,200,000,000	4,000,000,000
Turkey and Bulgaria	800,000,000	1,100,000,000	1,900,000,000	350,000,000
Total	\$9,800,000,000	\$33,950,000,000	\$43,750,000,000	\$10,350,000,000
Grand total	28,290,000,000	98,654,000,000	126,944,000,000	42,950,000,000

capitalization, that it would become a temptation to decrease outputs and take two or three times the usual length of time for mining the gold, as when once mined all hope for further profit is gone.

To illustrate, let us assume an invested capital of \$1,000,000 and a net income of \$1,000,000 in sight in the ground and with little hope of more, but to be taken out in one or more years. What is the proper course for the management to recommend to its shareholders? If it is taken out in one year, the rate is 100% and the company must pay the Government \$479,400. If in five years, the rate is 20%, and the company would have to pay a tax equal to \$23,900 by 5, or \$119,500. If in ten years, the rate is 10%, and the company would have to pay a tax equal to \$1400 by 10, or \$14,000.

Should a small group of miners or prospectors form a small company, of say, \$10,000 to \$100,000 capital, and expend the entire capital but strike it rich and take out as net profit an amount equal to or more than the capital put in, in such case, would not they be obliged to turn over to the Government nearly half of their profits? And such being the case, is not the search for new gold deposits greatly discouraged by the tax?

It is my view that the elimination of all excess-profit taxes on gold mining and the encouraging of maximum outputs might in reality bring in greater revenue to the Government than the tax; for larger dividends paid to shareholders would mean greater revenue from individuals.

The table shows at a glance the great difference between the debts incurred by the Central Powers and those of the Allies. Taking into consideration the number of combatants and the necessary munitions and supplies used by them, is it not evident that the Central Powers are getting far more value for their debts than the Allies?

As regards the stock of gold on hand in the world and the amount held by the United States, used as money and security, the following quotation is given from the Report of the Secretary of the Treasury, 1917, page 24:

"The gold monetary stock (coin and bullion used as money) in the United States on November 1, 1917, is estimated at \$3,041,500,000. The increase in the past 10 months has been \$174,500,000; in the past three years \$1,236,500,000, while in the past five years it has been \$1,161,333,000. In five years the portion of the world's gold monetary stock held by the United States has increased from approximately one-fifth to more than one-third."

This indicates that the calculation made previously of the gold reserve in this paper corresponds closely with the estimate of the Secretary of the Treasury.

Accepting \$10,000,000,000 as the proper gold reserve of the world, it may be calculated that at the beginning of the War the gold reserve was 35% of the total debts of the belligerents, while at the present time, it is only 8%.

DISCUSSION. When prices of labor and commodities are so advanced that it is not possible for the majority of

THE VALLEY OF THE BODAIBO, OR LENA GOLDFIELD, IN SIBERIA

TRAMMING IN THE EL ORO MINE, MEXICO

the gold mines of the world to work at any profit, then labor and supply prices must become lower, or gold becomes automatically demonetized.

Gold coins can be considered storage-cells of human energy, as to obtain them labor of hand and brain must be expended; in fact, they are thus charged with human electro-motive force. They are able to give out strong genial currents of trade confidence, circulating and binding trade, and bringing together different industries and peoples in different lands; their value is not founded on the fiat of any one or more legislative bodies of one or more countries that may be experiencing fleeting prosperity, but they are certificates from Nature of man's work and accomplishment.

The electro-motive force of the storage-battery cells depends not only on the amount of the electricity poured into them, but also its pressure or intensity. In electrical parlance, the rate of flow is known as the amperes and the pressure the volts, while the power, the watts. In the gold cells filled with human energy, the amperes can be considered the number of workers and the volts the forces and tools placed at the disposal of the workers by discovery, science, and organization. The watts may be considered the labor force stored in the cell of coin.

In the mention of the labor elements poured into the cells, it must be understood that labor should include the work of managers, engineers, metallurgists, chemists, overseers, mechanics, and other skilled laborers, as well as the more unskilled work of drillers, trammers, and shovelers.

The electric storage battery of cells can be rendered useless or burnt up by excessive charges of current; they can also dry out and stop working, or be feebly active should there be an insufficient number of cells on the circuit to do the work demanded.

Translating these conditions to the human electro-motive coin-cell, the value of gold can be destroyed by its too great abundance and its too great ease of winning. History is almost uncanny in showing how visions of super-abundance as seen or painted by owners and miners have been doomed to disappointment, and how, considering time and averages, Nature has demanded full toll in labor for her gold.

The electric storage-cell can dry out and disintegrate unless refreshed with new current; this means that should the obtaining of new gold cease while drafts on the old coins are vastly increased, the whole storage-battery of gold energy may get so out of adjustment as not to do useful work and gold would become demonetized and the accumulated labor energy of centuries past, locked up in old coins, become inert and valueless. Should all gold mining stop or radically diminish, this would be the result.

As long as this country, or in fact any country, continues to measure values by a gold standard and pledge its credit on this basis, in the long run the cost of obtaining a new supply of gold must fix its limitations to the rise in wages and commodities. Gold is a sluggish governor and seems at times inoperative, but its plentifulness and cost of winning is ever operative, though not

the only factor in the rise and fall of prices. The great value of the gold coin is that it represents a past labor achievement and cannot be duplicated in the future without equivalent labor effort. Promissory bills or notes, or contingent division of profits made by governments, banks, or individuals, can be made mere scraps of paper almost overnight by war, revolution, or commercial failure, but for thousands of years gold, while showing fluctuation in purchasing power, has ever been valuable.

Our government securities and liberty bonds, pledged on a gold basis, take the place of gold coins only as long as the people in this and foreign countries have faith that the Government can make good its promises; when this is seriously doubted by the many, gold will go to a premium.

The great gold reserves of the past would not be so necessary if the recognition of the fundamental necessity of measuring gold-values in units of labor necessary to win it were better recognized and insisted upon by governments that pledge their credit on a gold basis. Safely to lessen gold reserves while upholding the legal gold standard is the great financial problem of the day for this and other countries. To attempt to adjust the value of gold coin by changing its weight in fine gold by government fiat, would be to take away all intrinsic merit from the gold standard and result in confusion and utter lack of financial faith and confidence. The temptation to enlarge obligations and thus reduce gold reserves to an inadequate amount and meet the difficulty by refusing to pay coin for gold pledges also has great financial dangers.

The conception and definition of money has been one of the most fruitful subjects of disagreement, argument, and books known to man. It would seem, however, that the main functions of money are first, facilitating exchange; second, a means of estimating comparative values of commodities.

The unreality of paper money is forced upon me by my study of gold, the happenings of the time, and the outlook for the future. Money must in a large measure be based on sentiment and on good faith, for money, even including gold, has no intrinsic value except as an incentive or stimulant to future human enterprise, effort, and labor. Its stored value vanishes when the mass of the people repudiate it. When faith in it gives out, those that may seize and wish to make new divisions will find only waste-paper in the bonds, notes, and securities so eagerly desired and coveted.

Money can be converted into reality only by working masses led by efficient officers, and who not only make use of the muscular energy of the masses, but harness into service all the impersonal obedient servitors that discovery, invention, science, and engineering have placed at command, which force far exceeds all the muscular energy of man.

The payers of income-tax in 1915 did not amount to more than one-third of one per cent of the population. The envied rich amount to only a fraction of this number. They may enjoy pride of possession in the paper showings of their bank deposits and lists of securities, also the power it gives, but their absorbing power of that

which money can really give to them individually is very small and confined largely to what they and their families can eat, drink, and wear. All other possessions they must share or pass on to others. The rich are merely defectors, gates, or valves in energy currents. The greatest wealth by the individual has been obtained by organizing labor and producing the necessities of the many at the lowest prices and taking small profits per unit, but with the greatest number of units. As labor in its broader sense has been organized and stimulated to produce a maximum amount of commodities, it provides for its own necessities and comfort as well as that of the few and makes possible a greater division of such commodities among themselves. Thus great production is beneficial to the many as much as, and in proportion more than, to the few.

The decennial census of 1910 shows that about 93% of the male population of the United States over 21 years of age is occupied in gainful pursuits. A far more difficult problem than the destruction of capital would arise among the workers should the present order of things be suddenly abolished, which would be how a fair, satisfactory, stimulating division of salaries and wages could be arranged and enforced among the workers, so that they would have more leisure and at the same time obtain more wants and necessities.

Any advance in wages of one class of workers must in fairness be followed by proportionate increases in the wages of other classes and as the laborer's wants and requirements for subsistence and comfort are dependable on his fellow-worker, so must the cost of his subsistence increase as his own and other wages are raised. Thus, in the end no material gain can be obtained by labor unless there is some corresponding advance in the output of his work. The Government at the present time is the greatest employer of labor and purchaser of commodities. The danger of allowing the prices of commodities to rise above the future cost necessary for obtaining gold, it is hoped has been made plain. Certainly the Government should insist on the stoppage of all classes of profiteering, but how is it possible to fix prices of any commodity and make low bids possible unless there is some limit fixed upon wages and salaries?

The War must be won and it will take money as well as men to accomplish it. However, it does not help matters to pledge credit unnecessarily to please or placate either labor or capital, and the more we get for money on a gold basis at the present time the less will be the burden of debts incurred on future generations, which must of necessity be paid by the mass of the people rather than the few. The financial integrity of the country has been pledged on a gold basis. As 90% of the gold output of the world comes from the Allies' territories, as a war measure it is plain that it is to the advantage of the Allies to uphold the gold standard. For the past ten years the world's yearly output of gold has been almost stationary, and the present high cost of labor and supplies is acting very seriously against any increased production. To stop gold mining in a time of financial stress, as has been indicated, would be like closing the doors of a bank

when a run is made upon it. It therefore must be evident that it is vital for this and all Allied countries to encourage gold mining as far as possible.

Unfortunately but little help can be directly extended to the gold industry, but as far as possible, encouragement should be given and the excess war-profits tax placed upon this industry should be re-considered, for while the War may have proved profitable to every other class of industry in the matter of earnings, certainly it has been seriously injurious to the gold miner.

Indirectly, the gold industry, as well as new issues of Liberty Loan bonds, can be greatly helped by the reduction in prices of all necessary commodities, and this certainly should be seriously, judiciously, and fairly taken in hand by the Government.

The War is to be won by the efficiency, harmony, and morale of the workers behind the firing lines as much as by the exercise of these qualities by the soldiers at the front. The right conception of what gold, and in fact money in any form, has the power of doing, or not doing, seems to me a matter of most vital concern at the present time. A better understanding of this problem, I believe, would tend to knot together governments, labor, and capital and make for efficiency, harmony, and happiness.

Transvaal Mining Statistics

Final figures for 1917, compared with 1916, are now available, showing the following results:

	1917	1916
Stamps crushing	9,470	9,727
Tube-mills grinding	332	321
Ore treated, tons	27,862,851	29,175,468
Value per ton	27s.3d. (\$6.54)	26s.9d. (\$6.42)
Gold extracted	£38,323,921	£39,484,934
Silver extracted	£122,951
Operating costs, per ton. 19s.4d. (\$4.64)		18s.3d. (\$4.38)
Operating profit	£10,486,283	£11,881,294
Dividends declared	£6,718,694	£7,271,589
Coal mined, tons.	6,641,229	6,136,913

At the end of 1917 there were 31,705 whites and 256,304 kaffirs employed at all the mines throughout the Union of South Africa.

PEAT yields excellent fuel-gas when treated in a special gas-producer. Valuable by-products are recoverable in this process, and after these have been extracted, the gas is exceedingly desirable for the generation of heat and power. This is the most promising field for the utilization of peat. The gas can be compressed so as to cheapen the cost of piping it long distances to the point where it can be most economically utilized.

AMMONIA prices have been fixed by the Food Administration at 8½c. per pound for aqua ammonia in less than earload lots f.o.b. factory, and 30c. per pound for the anhydrous grade. This has been arranged by agreement with all the leading producers, in order to avoid profiteering. If higher prices are quoted, under the conditions stated, the fact should be reported for adjustment by the Food Administration.

Mr. Guggenheim on Industrial Conditions

In the nineteenth annual report of the American Smelting & Refining Co., just issued, Daniel Guggenheim says:

The peak of high prices for metals, excepting that of zinc, was reached during the first half of the year. Since then, there have been very serious declines in all metals, as follows: Copper from 33c. to 23½c., lead from 11c. to 5½c., silver from \$1.09 to 78c., and zinc from 13c. to 7½c. These results have been partly brought about by governmental actions.

On the other hand, all our expenses of operations have constantly increased and are still increasing. Everyone is acquainted with the greatly increased cost of fuel. All our supplies and building materials are costing from 50 to 150% more than normally. But our greatest difficulties have been, and are, in connection with the lack of supply and the constantly increasing demand for labor. Therefore, our costs of smelting and refining are greater month by month, but our receipts are fixed.

It has always been the policy of the Company to make long-time contracts for ore and bullion, at a fixed price for smelting and refining; this has permitted continuous running of our works, because plans could always be made intelligently and without risk for enlargement or making expenditures to reduce costs. While the charge in such contracts was fixed, the Company had a certain interest in the metal recoveries. Under economic laws, if costs of operation increased, it would be on account of generally increased values, and the interest of the Company in the metal recoveries would equal the increased cost of smelting and refining.

The Company is now suffering from the entire lack of economic law, and is operating under the direction of governmental commissions, whereby the value of the metal products of the Company is fixed. But the cost of labor and supplies is not fixed; in fact, owing to the various governmental contracts for shipbuilding and other construction of great magnitude, which have been made on the basis of cost plus a commission, the contractors have no interest in holding labor costs at a point where a profit can be made, and, in fact, their own interests are in favor of as high a cost as can be in any way justified.

By these two governmental actions, first, by reducing the value of our product, and second, by constantly increasing our cost, this great corporation, producing what is absolutely necessary to the Government in carrying on the War, is having its ability to pay a fair return to its stockholders seriously jeopardized. While it may be said that the previous profits were excessive, had it not been for such profits, the Company would not have been able to enlarge its works and increase its output, all of which has been of vital necessity to the Government. These enlargements have been effected at a cost of fully \$15,000,000, all of which has been taken out of the earnings of the Company, and the enlarged capacity will

doubtless be entirely useless after the War demand ceases.

The three smelting works in Mexico, located respectively at Monterrey, Matehuala, and Aguascalientes, were started up in a small way during the first half of 1917, and it is hoped that the smelter at Chihuahua will soon be blown-in. There is no immediate prospect of the smelter at Velardeña being put into commission, or of the mining properties in that section being opened, as bands of bandits are still disagreeably active in that vicinity. None of the very valuable mines of the Company around Chihuahua have been operated as yet, and the same is true with the copper properties around Matehuala. Our smelting works have not been worked to capacity, and the uncertainties as to transportation and fuel, together with the fact that costs have been quite as greatly increased in Mexico as in this country, have not made for a profitable outcome. Nevertheless there has been a gradual improvement in this direction.

OIL-SHALES in South Africa have been found in the Karoo formation, as developed in the eastern part of the Union, over a very wide area extending from Middelburg in the Transvaal to Nahankwe in the Matatiele district of East Griqualand. They occur in at least two divisions of the Karoo system, namely, the Stormberg series and the Coal Measure series of the Transvaal and Northern Natal, and at least two horizons in the last-named group of rocks. The existence of the shales has now been known for over 25 years. While no great measure of success has so far attended the efforts of the various companies and syndicates that have been formed to work, or more correctly speaking, to explore the deposits, the prospects of establishing a shale-oil industry appear hopeful. Four areas have up to the present attracted particular notice. They are: (1) the central portion of the Ermelo district of the Transvaal; (2) the Wakkerstroom district of the Transvaal; (3) the north-eastern portion of the Utrecht district of Natal; (4) the eastern part of Impendhle county, Natal. In the three first-named areas the oil-shales occur in the Coal Measure series; in the last named in the Stormberg series. Distillation tests made on shale from Mooifontein yielded from 30 to 32½ gal. of crude oil per ton, comparing favorably with the Scotch shale. In the Utrecht district there is enough shale available to warrant the erection of a 300-ton treatment plant.

PRIMARY ALUMINUM made in the United States in 1917 was valued at \$45,882,000, an increase of \$11,982,000 over the value of that made in 1916. This increase appears to be due chiefly to an increase in the quantity of metal produced, but in part to an increase in the price.

SOLDER for aluminum, composed of zinc and tin, the former being in the proportion of two to one, and a relatively small proportion of sal-ammoniac, was recently granted patent No. 1,256,285, to J. J. Aubertin, of St. Louis, Missouri.

Sodium Cyanide

By W. J. SHARWOOD

*The contradictory evidence given by certain 'experts' in a recent sensational murder trial indicates an imperfect realization, even by some chemists, of the fact that commercial potassium cyanide can scarcely be said to exist at the present time, its place having been usurped by the sodium compound. Sodium cyanide is now widely used as a solvent of the precious metals in ore, and in electro-plating. It is also a source of hydrocyanic acid for fumigation, especially in Western orchards where gaseous hydrocyanic acid is applied as an insecticide to individual trees, which are covered with tents during the process.

The sodium cyanide of commerce is one of the purest technical salts now available, containing 96 to 98% NaCN, with less impurity than is found in most samples of potassium cyanide sold as chemically pure. Chemists might with advantage make a point of recognizing the use of sodium cyanide, and call it by that name in their laboratories. As with so many other alkali-metal salts, we can now use the sodium instead of the potassium compound as a reagent, except in the few cases where the potassium ion is essential to the reaction, or where there is some marked difference in solubility. Sodium cyanide not only contains less carbonate and sulphide, but is cheaper, reacts identically with the salts of silver, copper, zinc, etc., except in concentrated solutions, and is more permanent in solution than ordinary potassium cyanide, showing less decomposition and no discoloration on keeping. It has an additional advantage in not being deliquescent.

The alkaline cyanide now sold must be much more poisonous than the old material, which was no doubt the basis of most of the familiar statements as to its lethal effects. Modern sodium cyanide—commercial as well as e. p.—contains 50 to 52% cyanogen, or practically four times as much as the material formerly sold, and is presumably four times as lethal in its action.

Pure KCN contains, by calculation, 39.97% of CN; pure NaCN contains a much higher proportion, 53.07% CN. For most purposes these are taken as 40% and 53%, respectively. As the potassium in commercial cyanide was gradually replaced by the lighter atom of sodium, other things remaining the same, the proportion of cyanogen was correspondingly increased. This allowed manufacturers to make a salt containing a large proportion of impurity, which would still titrate 38 or 39% cyanogen and would be reported on the old basis as 97 or 98% KCN. Pure sodium cyanide, by the same system, would have been reported as 5300/40 or 132.8% KCN. In fact

sodium cyanide was sometimes deliberately diluted with inert material (carbonate, etc.) to supply the demand for 98% KCN. At first there was a prejudice against the use of sodium cyanide in gold extraction, some early experiences indicating that it was less efficient, but laboratory tests indicate that equivalent amounts of the cyanides of potassium, sodium, and calcium are equal in effect, and sodium cyanide is now almost exclusively used in the industry. In fact, with the present shortage of potassium, owing to war and other conditions, it would be impossible to supply the potassium compound in anything like the required quantity.

Until recently, however, cyanide has continued to be sold and used on the basis of its KCN equivalent, even if no trace of potassium was present; thus commercial NaCN was commonly sold as 128% KCN, and most works using cyanide also continued to make up their solutions on the basis of KCN. For the past year cyanide has for the first time been generally sold on the more rational basis of its cyanogen, or its actual NaCN, content; thus the highest grade is now offered as either sodium cyanide 96 to 98% or cyanogen 51 to 52%, while the old so-called 98% KCN used to carry about 39% cyanogen. Four pounds of this sodium cyanide are therefore chemically equivalent, and actually equal in effect as a solvent, etc., to about 5 lb. of the old potassium cyanide, and there is a corresponding saving of about one-fifth in freight and storage. There is no reason why all users of cyanide should not accept the rational method of reporting the concentration of their solutions in terms of the sodium cyanide which they actually are using, and discard the absurd fiction of calling it—or translating it into—potassium cyanide, which causes unnecessary trouble in making up solutions, and so forth.

At various times commercial cyanide has been cast as thin slabs, and in large bricks weighing up to 50 lb. or more. Some produced in the wet way has been sold in granular form, and some briquetted. The most recent and convenient system is to cast it mechanically into uniform egg-shaped cakes weighing an ounce each, so that for many purposes, such as fumigation, no further weighing is necessary. It was formerly shipped in boxes with an air-tight lining of sheet-zinc, of 112 or 224 lb. each; tin-plate is now used for lining and 200 lb. is the usual net weight.

For titrating potassium cyanide it has been the universal custom to make up a solution containing 1.303% silver nitrate, so that 1 cc. was equivalent to 10 mg. KCN. This was roughly 0.0767 N. For titrating commercial sodium cyanide it is possible, by a convenient coincidence, to use N/10 or N/20 silver solution without

*Abstract from 'Jour. Indus. and Eng. Chem.', April 1, 1918.

necessitating any calculation. One cubic centimetre of $N/10$ silver solution is equivalent (by Liebig's titration, or using the preferable modification with potassium iodide indicator) to 5.202 mg. of CN, or to exactly 9.802 mg. of NaCN. Now 98 is almost the exact percentage of actual NaCN in the high-grade commercial material now in use. Therefore we can titrate solutions with $N/10$ $AgNO_3$ and call 1 cc. equivalent to 10 mg. of the actual 98% salt, which has to be weighed-out in making-up the solutions. For technical purposes it is perhaps preferable to use $N/20$ solution (1 cc. = 5 mg. commercial NaCN) as the end-point with iodide indicator, it is very delicate, and the burette readings then also indicate pounds per ton of solution directly. For instance: taking a 10-cc. sample: suppose 2 cc. of $N/20$ silver nitrate is consumed; this indicates 10 mg. or 0.10% of commercial sodium cyanide in solution, or 2 lb. per ton of solution. The ton or fluid ton used in hydro-metallurgy is about 32 cu. ft., or the volume of 2000 lb. of water.

When determining sodium and potassium in a mixed cyanide—chlorides and carbonates being the usual impurities—it is often possible to work by directly evaporating with hydrochloric acid, gently igniting, and weighing the mixed chlorides remaining, and titrating chlorine in part of the residue. The following formula, based on 1914 atomic weights, gives the results in the most direct manner possible:

If A = grammes mixed chlorides, and

B = total grammes chlorine in mixed chlorides;

then K in grammes = $2.4286 A - 4.004 B$, and

Na in grammes = $3.004 B - 1.4286 A = A - B - K$.

Not infrequently the class of cyanide can be determined simply by titrating cyanogen and alkalinity in a freshly prepared solution, using methyl orange as indicator.

It is important, when testing cyanides for the presence of alkaline sulphide, to prepare the solution at the moment of making the test; or, what is better, of dissolving the solid cyanide in the reagent to be applied. If the cyanide is dissolved in water and allowed to stand even a few minutes, the sulphide content may be seriously diminished, and traces of sulphide may be easily overlooked. Three simple methods are available: shaking with fine lead carbonate suspended in water; dissolving the solid cyanide in a solution of silver nitrate containing slightly less than 1 mol. $AgNO_3$ for 2 equiv. CN; or dissolving the solid cyanide in a little mercuric chloride solution. Each of these reagents yields a black precipitate or dark coloration. The sulphide may be quantitatively determined by the silver or mercury method.

While sodium cyanide is not deliquescent, it is decidedly more soluble in water than potassium cyanide. In dilute solutions there is no apparent difference in the stability of sodium as compared with potassium cyanide. In each case decomposition is greatly increased by access of air and retarded by presence of free alkali. Tests indicate that in strong solutions there is comparatively

little difference in stability, the advantage, if any, lying on the side of the sodium compound, which lost about 40% of its cyanogen in 38 months, against nearly 50% lost by commercial potassium cyanide.

Manganese Possibilities in Eastern Cuba

While several hundred manganese mining claims have been filed during the past year at the Mining Bureau of this Province, in only a small number has it been demonstrated that they may be profitably operated, even at present high prices for the ore. The lack of proper transportation facilities and of good roads is the great drawback to development of the industry here. With three exceptions the mines have to haul their ore to the railroad in ox-carts and mule-carts, or by pack-mules, a distance of 3 to 15 miles, and at a cost of \$3.50 to \$10 per ton. As most of the ores are low grade, and practically none comes up to the standard of 48% metallic manganese, it is difficult to operate at a profit under the conditions that exist. The roads that are available during the few months of the dry season become practically impassable in the season of abundant rainfall, usually from April to November. Some of the American mine operators are now using motor-trucks and tractors for transportation of ore, and it is hoped that by this means some of the difficulties may be overcome.

The manganese mines or claims of this Province may be divided into nine groups: Cristo, Ponupo, San Nicolas, Palmarito, Los Negros, Santa Rita, Guisa, Sabanilla, and South Coast. The most important are the Ponupo and Cristo. The Ponupo produces at present about 5000 tons of ore per month. It is chiefly low grade, averaging from 38 to 40%, and is rather low in silica and iron. As this group is near the line of the railroad, the ore is mined and shipped at a profit under present prices. The Cristo consists of several small claims at present producing 4000 tons of ore monthly. The mineral is slightly higher in manganese and about the same in silica and iron as the Ponupo ore, but the greater part of it requires washing. The Palmarito and Los Negros groups produce each about 1000 tons monthly. The ore from them is high grade and low in silica and iron. Considerable modern machinery has recently been installed at the San Nicolas mines, and it is expected that several thousand tons monthly will soon be produced from this group. The remaining four groups have a combined monthly production at present estimated at 1000 tons, making the total for the Province approximately 12,000 tons monthly, all of which is exported to the United States through the ports of Santiago and Nipe. The declared exports of manganese ore from the Province of Oriente in 1917 were valued at \$567,849, of which a large proportion was shipped through the port of Santiago de Cuba, and the remainder from Antilla (Nipe).—'Commerce Report', March 27.

GOLD EXPORTS to Mexico according to official figures were \$1,884,813 against imports of \$440,603 in December.

Improved Flotation Dryer

By S. PAUL LINDAU and W. E. EVANS

The flotation concentrate reaching the smelter of the St. Joseph Lead Co. at Herculanum, Missouri, at times contains from 12 to 15% water; this must be dried or reduced to about 6 to 7% before incorporating it into the regular Dwight-Lloyd sintering charge. One method of accomplishing this is to unload the material on stock-piles, and depend on natural atmospheric agencies, the

An old discarded pan-conveyor, which was formerly used in the now extinct 16-pot Savelsburg process plant, is utilized. This conveyor is 125 ft. long, with pans 24 by 12 in., having overlapping ends. This is placed at an incline of 30°, running at a speed of about three feet per minute. There are six oil-burners evenly spaced, underneath the ascending and above the descending pans, to supply the necessary heat. The conveyor is housed on top and sides, thus retaining as much heat as possible. A shovelful of the wet concentrate is placed on top of each pan; as this material travels upward it is broken

LONGITUDINAL SECTION

THE DRYING PLANT FOR FLOTATION CONCENTRATE IN USE AT HERCULANEUM

length of time depending on the time of year and kind of weather.

A more satisfactory method is now being employed on part of this material with great success. This method is as follows:

ten times by passing under the prongs of old eke-forks that are weighted at one end, causing the prongs to scrape along the surface of the conveyor. The material is discharged into railroad cars and taken to the ore-bins.

This dryer has a capacity of 50 tons per 24 hours.

[The success of this method of drying flotation concentrate depends upon the cost of the oil used to obtain the necessary heat. The consumption of oil is at the rate of 20 gallons per ton, at a cost of 5 cents per gallon, equal to \$1 per ton of concentrate. These were the figures quoted last October.—EDITOR.]

A PAN-CONVEYOR DRYING-MACHINE FOR FLOTATION CONCENTRATE

ZIRCONIUM is being used to make a high-speed alloy for tools, containing 1.5% Zr with Si 6, Al 6, Ni 86.4, and C 0.1%. The alloy was developed by G. L. Kelley and A. H. Miller for the Midvale Steel Company.

Converting an Agitator Into a Continuous Thickener

By V. T. EDQUIST

*Vacuum-filtration was superseded by continuous decantation at the Yuanmi gold mine, Western Australia, early in 1917. The ore contains arsenical pyrite and antimony sulphide. It is roasted, ground fine, and agitated with cyanide. Dissolved losses in the residue made some change necessary, so decantation was successfully tried. The operation is dilution of pulp, followed by part dewatering, using two 20 by 8-ft. mechanical agitators as continuous thickeners. By repeated dilution and dewatering of pulp, the originally contained gold solution is almost entirely removed. This is the C. C. D. process as known in America.

To convert an ordinary 20 by 8-ft. agitator into a continuous thickener, the bevel-pinion and crown-wheel driving the agitator-arms were removed, and a worm and worm-wheel substituted. This reduced the speed to 1 r.p.m. The supporting stays were shortened, and the

The capacity of one of these 20 by 8-ft. thickeners on Yuanmi roasted ore-pulp, when the ratio of solution to solids in the feed is 5 to 1, the underflow 1 to 1, and the overflow clear, is from 100 to 110 tons per 24 hours.

The total cost of the complete conversion from vacuum-filtration to continuous decantation was £189 (\$907).

Signs

By CECIL W. LEARY

Some men seem to take a secret delight in that old school-boy prank of defacing and mutilating sign-boards. In the mines they pick on the signs along the drifts, and it seems that when they have a minute or two to spare they burn or scratch out letters so as to deface them.

On several occasions I have overheard men laughing and talking about the way in which they had changed signs from one drift to another, and what a good joke it was to watch the greenhorn get on the wrong track. I appreciated the joke, but if a fire had broken out about the time they were playing their little prank it would not have been so amusing to these men to know that they had been the means of spoiling the greenhorn's only chance of getting out.

These signs are not an order, nor a command from a shift-boss, and you are not spiting the company when you deface them. They are put in place for your, and your fellow workmen's welfare. If you have an occasional moment to spare, use it in making the place safe or in giving the greenhorn advice that will help him.—'The Anode', March 1918.

DETAILS FOR AGITATOR-THICKENER

agitator-arms bent up so that the ends were raised about two feet. A hole was cut in the vat-bottom as near the centre as possible, and a 4-in. plug-valve flanged on. From this valve a 3-in. pipe leads away to the desired point of discharge.

After starting, the natural settlement of slime under the bent-up agitator-arms forms a smooth bottom sloping to the centre. The overflow-pipes are arranged as shown in a sketch. The pipes are placed near to, but not touching the side of the vat, and the length of the moving agitator-arm is regulated so as to clear them. The upper end of each vertical pipe is threaded, and an easy running socket screwed on. By screwing these sockets up or down the height may be regulated exactly, and an even overflow obtained. This arrangement gives an overflow from four points a few inches from the side of the vat, and dispenses with the costly annular overflow-channel. The agitator lifting-gear remains unaltered, so that the spindle and arms may be raised or lowered as occasion demands.

ALUMINUM SULPHATE, used for water filtration, is sold on its water-soluble aluminum content, and on the excess of $\text{Al}_2\text{O}_3\text{H}_4$ over what is required theoretically to combine with sulphuric acid. Estimated on the basis of 17% Al_2O_3 at 2c. per lb., an alum with 19.5% Al_2O_3 is worth $\frac{1}{2}$ c. more, and an alum with 12.8% Al_2O_3 is worth $\frac{1}{2}$ c. less. A good basic aluminum sulphate should be in lumps from a half inch to two inches in diameter; it should contain not less than 17% water-soluble aluminum calculated as Al_2O_3 ; it should have a basicity ratio of 0.03, that is, it should contain 0.5 to 1% more Al_2O_3 than is theoretically required to combine with the sulphuric acid present; and it should have less than 1% total iron. The process employed for manufacturing aluminum sulphate consists in mixing bauxite with sulphuric acid in lead-lined tanks, then boiling for six to eight hours. The solution formed after the reaction between bauxite and acid has taken place, is a mixture of $\text{Al}_2(\text{SO}_4)_3$ and silica. In order to obtain a clear solution it is necessary to filter the mixture, which is difficult, tedious, and costly. The alum solution is next boiled to expel the excess of water. After being concentrated from a density of 25° or 30° to 50° or 60° B., the solution is discharged into trays. On cooling it crystallizes as alum cake. This is crushed, and is shipped in bulk, barrels, or sacks.

*Abstract from 'Monthly Journal,' Chamber of Mines, Western Australia, November 30, 1917.

Silver Bill Debate in the House of Representatives

*MR. GLASS. Mr. Speaker, when this measure was originally drawn some months ago, it was designed to meet and overcome the difficulty that had risen in our foreign-trade relations, involving a rather serious discrimination against this country in the matter of foreign exchange. Importers of many necessary articles were subject to great loss by reason of the depreciation of the American dollar in neutral countries in Europe and Asia, particularly in Spain and the Scandinavian nations, as to Europe, and in the Orient, India and China. In that view it was not an emergency measure. But within the last 10 days circumstances, of which I am not at liberty to speak in detail, have arisen which make action by Congress imperative. For that reason the bill, by unanimous action of the Committee on Banking and Currency of the other body, was presented to the Senate, and, without division, passed. It was taken up for consideration on Friday and Saturday of last week by the House Committee on Banking and Currency, and, at an exceptionally largely attended meeting, unanimously ordered to be reported to the House. In our trade relations with the Orient, and particularly with India, we are put to the necessity of paying our balances in metal, and, on account of the large importations of jute, burlap, and other materials used in the handling and distribution of our crops, we are obliged to meet a large exchange balance to our very great disadvantage. It shall be necessary for this country to ship to India, for the next ensuing 16 months, at least, about \$100,000,000 of gold to meet our importations, or otherwise to do what this bill proposes to do, borrow from the Treasury the only available stock of silver in the world at this time, and ship it to India to meet trade balances. It is not necessary to say to the House that, gold being our primary money, every dollar of it that we shall export circumscribes our ability to meet the extraordinary commercial requirements of our own country at this time. In short, if we do not pass this bill immediately, we may be put to the necessity of shipping gold rather than silver to India. I transgress no propriety and reveal nothing that should not be disclosed to the House when I say that the governor of the Federal Reserve Board stated to the committee that the board had already felt obliged to give the large imports of jute, burlap, and other materials which we are obliged to have the assurance that if something of this sort should not be done immediately by Congress the Federal Reserve Banks would assure them the gold necessary to meet trade balances. The bill provides that there shall be a retirement, gradual or immediate, as circumstances may require, of \$350,000,000 of outstanding silver certificates; and as those silver certificates are retired a like amount of silver coin in the Treasury, held

as a cover for the silver certificates, will be broken up and melted into silver bullion and sold by the Secretary of the Treasury to meet foreign exchange exigencies and to avert serious trouble in India. The Congress knows that India uses not exclusively, but almost exclusively, silver as its metallic currency. Any deficiency in the circulating medium that may be occasioned by the gradual or speedy retirement of \$350,000,000 of silver certificates is to be met by the issuance, under authority of the Secretary of the Treasury of the Federal reserve bank-notes, based on short-time gold certificates and notes of the United States. When the emergency shall have passed or the War ended, the Secretary of the Treasury is authorized to purchase an equivalent amount of silver to that which may be utilized in this transaction to replace the silver thus loaned to the British government, and used for foreign exchange purposes, by the re-coinage of a like amount of silver dollars, upon which may be issued a like amount of silver certificates.

MR. LA FOLLETTE. The gentleman stated that there would be a trade balance of \$100,000,000 in the next 16 months between this country and India. That accounts for \$100,000,000. Why the other \$250,000,000?

MR. GLASS. The other \$250,000,000 is to meet foreign exchange accounts with other countries and especially is to be used to counter an exigency that vitally affects our Allies in the conduct of the War. Just in the degree that it vitally affects them it vitally affects us. I will read to the House a telegram that was sent to me from Deming, N. M., while I was absent from the city attending the funeral of my late colleague, Mr. Jones, by Secretary McAdoo in which he says:

"A war emergency of the utmost urgency makes the prompt passage of the Pittman bill imperative. I commend this subject earnestly to the consideration of yourself and your associates on your committee. Will you please permit Assistant Secretary Loeffingwell to lay before you my views about this matter?"

WILLIAM G. McADOO,
Secretary of the Treasury."

MR. MOORE of Pennsylvania. It is a situation affecting our Allies at least equally with the United States?

MR. GLASS. It is a situation we are obliged to meet. It is rather distressing to the chairman of the Committee on Banking and Currency to feel compelled to bring to the House a measure all of the details of which he is not at liberty to discuss fully, and to ask the House, upon its faith in him and his associates of the committee, acting as a unit, to accept the bill, but that is precisely the situation. Upon my return to Washington on Saturday, I found that the Committee on Banking and Currency had had a meeting and such hearings as were possible. In addition I personally made inquiry in every responsible

*Excerpt from Congressional Record, April 22, 1918.

quarter and satisfied myself that there was nothing else to do but to pass the Senate bill if we would avert trouble. To re-assure the House even more fully, if I can, I present this letter, sent to me by the President under date of April 21:

"THE WHITE HOUSE,

WASHINGTON, April 21, 1918.

HON. CARTER GLASS,
Washington, D. C.

MY DEAR MR. GLASS: I am taking the liberty of writing you to ask if the early report and passage of the silver bill will be possible. Circumstances have arisen which make the passage of this bill a genuine war emergency; otherwise I would not suggest so immediate action upon it. The circumstances, however, are pressing, and I beg you to believe, justify me in making this request. I believe that you have been informed from the Treasury Department just what the exigency is.

Cordially and sincerely yours,

WOODROW WILSON."

MR. HAYES. Mr. Speaker, under ordinary circumstances, I should be opposing this bill very strenuously on several grounds. If the country were not in this War, and the present emergency were not upon us, I should regard this bill as a piece of economic and financial folly. There are several things in it that, if it were in my power, I would change. I would amend it radically, but from the information that has been conveyed to the members of the committee by the President, the Secretary of the Treasury, and the Federal Reserve Board, some of which information has been stated already by the gentleman from Virginia (Mr. Glass), I conclude that this is not only an emergency measure but a matter of the greatest urgency. I therefore feel it to be my bounden duty to support it as it is, since under the rule just adopted, it cannot be amended.

MR. WOOD OF INDIANA. It comes to us rather suddenly here. I want to inquire if there is any evidence before your committee as to whether or not England knew of this exigency for some time, and considered it before this was sprung on the United States.

MR. HAYES. England has known for some time that she had out obligations, of course, but she was not familiar, and the world has not been made familiar, and is not now familiar, and it is not desirable that it should become familiar, with the dangers that lurk in the immediate future.

MR. WOOD OF INDIANA. Did England take any steps to relieve this situation?

MR. HAYES. Certainly; all the steps that were possible. As the gentleman from Virginia (Mr. Glass) has stated, the United States has the only great supply of silver that is in the world.

MR. WOOD OF INDIANA. I saw a statement in the paper this morning, and I think it would be fair that the gentlemen should know of it, to the effect that in this transaction there is a speculation of over \$70,000,000 by bankers of England. Does the gentleman know anything about that?

MR. HAYES. I know nothing about that. I want to

say that under ordinary circumstances I should insist upon acting upon my own judgment and experience, after many years of study of financial questions; but under the present circumstances, when the Commander-in-Chief of the Army and Navy of the United States comes to me and says, "The passage of this bill is a most vital war necessity," I sink my own judgment and my own feeling in the matter and yield to his urgent request as if it were a command. (Applause). Although the circumstances surrounding this emergency have been quite fully explained to the members of the committee, many other things are doubtless known to the President that he is not at liberty to explain to the members of the committee; necessarily information must be open to him that he could not disclose to us.

Metal Business of the A. S. & R. Co.

Metals and other products sold by this company during 1917 realized \$427,189,915. Operating statistics are as follows:

	1915	1916	1917
Men employed, excluding Mexico	15,556	21,073	24,698
Wages and salaries, excluding Mexico	\$11,392,503	\$17,047,944	\$24,497,836
Average wages per 8-hour day.	\$2.44	\$2.70	\$3.31
Charge smelted, tons.	4,153,092	4,789,474	5,918,924
Bullion refined, tons.	579,880	677,460	706,875
Coal used, tons.	604,394	724,595	787,800
Coke used, tons.	401,511	454,468	592,765
Fuel-oil used, barrels.	829,304	1,107,285	1,560,535

Mixed metals sold, pounds.	2,566,255	2,831,617	6,188,045

POTASH is recoverable electrolytically by a patented method devised by E. L. Anderson. The source of potash in this case is feldspar. It is ground and mixed with carbon, and the mixture is electrolyzed in a solution of H_2SiF_6 , producing KOH.

WASTAGE at the Philadelphia Mint in 1917 in coining 285,646,712 pieces of silver and copper domestic coin, and \$11,075,110 pieces for Central and South America, was only \$918. The metal handled amounted to 2007 tons.

SILVER production of the Kongsberg mines, Norway, during the last fiscal year amounted to 8072 kg., equal to 259,500 oz. The average price received was 93.81 crowns, or \$25.14 per kg., giving a total of \$202,855.

REVIEW OF MINING

NEW YORK

A. I. M. E. Meeting: Taxation and New Cornelia Copper Mine.—Mexican Railways.—Platinum.

The April meeting of the New York Section of the A. I. M. E. was held at the Machinery Club on April 23, preceded by the usual informal dinner. The subject for discussion was the report recently compiled on mine taxation and price-fixing by a committee consisting of J. Parke Channing, C. F. Kelley, and J. V. N. Dorr. Unfortunately, interest in the matter appeared to be at a low ebb and there was no comment, a result attributable to some extent to the absence of the three gentlemen mentioned. The report merits wide attention, but appreciation of the work and discussion of the conclusions reached would have been facilitated if a summary could have been presented that would have enabled the average mining engineer to comprehend the issues at stake, without the loss of time involved in the examination of the legal intricacies of the question. After the passage of a formal vote of thanks, L. D. Ricketts gave an interesting account of mining and metallurgical operations at the Ajo (New Cornelia) copper mine in Arizona. Motion pictures were shown illustrating the normal life in the township which, during the past few years, has sprung into existence on the Arizona desert. Realistic representations of blasting gave members an idea of the scale on which such operations are being carried on, and the difficulties encountered in handling and reducing the enormous masses of rock freed by the explosion. Mechanical arrangements for the transport and reduction of the ore to leaching size (3-mesh), indicated a perfection of design and an elimination of unnecessary handling. Ore from the cars is first discharged into one No. 24 Allis-Chalmers gyratory-crusher where it is reduced to 6-in. size. This delivers to four No. 8 machines of the same type, which are hardly sufficient for the work. From here the crushed ore is delivered by belt-conveyor to steel storage-bins from whence it is fed to four 48-in. Symons horizontal disc-crushers, operating in closed-circuit with stationary screens and ultimately delivering a 3-mesh product. Particular interest was displayed in the pictures showing the method of filling the 500-ton leaching-vats by means of a belt-conveyor with an automatic tripper which delivers the material evenly across the width of the vat in successive diagonal layers. This ensures a desirable classification of the material, whereby the coarse particles roll to the bottom and form a protective layer, which minimizes the passage of fine through the perforations of the filter-bottom. This idea was apparently borrowed from Chuquicamata. The method of applying the solution was shown, Dr. Ricketts explaining that upward counter-current leaching is adopted. The success of this method at Ajo, and the small amount of trouble experienced with accumulations of slime underneath the filter-bottom would suggest a wider application of the idea to methods where leaching of coarsely-broken material is feasible, such as the Chilean nitrate industry. An electrically operated 14-ton Hurlitt excavator is used for discharging the vats, the arrangement indicating the advantage of ample capacity as a factor in saving time. The pictures showing the handling of compressed iron scrap by means of lifting-magnets, the precipi-

tating-launders, and the electrolytic department, gave a complete insight into the final operations, and were much appreciated. In response to an inquiry it was stated that the work had not been carried on long enough to make a definite statement as to metallurgical results, although the amount now recovered was nearing 80% of the copper content of the ore. In this connection, Dr. Ricketts made some pertinent remarks, which supported the contention that in wet-chemical methods of treatment, such as the one described, the extraction of the metal from the ore by means of a solvent is not to be confused with recovery; and that the calculation of percentage recovery is the basic factor on which considerations of ultimate success or failure can alone be gauged. In conclusion it was announced that this outpost of civilization was so awake to its national obligations that no less than 90% of the Americans and 20% of the Mexicans had subscribed to the third Liberty Loan.

At a meeting of shareholders of the National Railways of Mexico, held at Mexico City during the past week, Henry Bruère was among those elected to comprise the New York board of directors. He is the vice-president of the American Metal Co., who recently left here for Switzerland to arrange for the elimination of German control in the company's Mexican interests.

The extension of price-fixing to platinum, foreshadowed in a recent report from Washington that the metal would be commandeered at the fixed price of \$100 per ounce, has not met with unanimous approval. Although the Government prohibited the sale of the metal by dealers or its manufacture into jewelry by craftsmen some time ago, the fact remains that no steps have been taken to relieve them of their stocks—a condition which must inevitably entail loss unless they evade the restrictions. A great deal of misapprehension has existed throughout the country with reference to the original order. Many people construed it to mean that it was illegal to have unworked platinum in their possession and promptly sent their supplies to Washington, only to find that the Government had no intention of buying. The tentative price of \$100 per ounce now mentioned will discourage speculation in the metal and will offer no inducement to dealers who have the idea that the metal may be collected now and re-sold later to the Government at an enhanced price.

LAS VEGAS, NEVADA

Manganese Ore of the District.

The Manganese Association sold its lease, running about three years, to Los Angeles people for \$87,500. From this, \$16,000 debts of the Association will be paid. The deal also includes some additional claims, locations made by the Association, of ground adjoining the three original claims; also the contracts with Suffer & Co. of New York for delivery of 90,000 tons, within 10 months. Some ore, possibly 2000 tons, has already been delivered on this contract. There is a prior contract, of 1000 tons per month, to McCarthy. The ore is peculiar. It is light (probably 'bog' ore) 35 cu. ft. to a ton. It is quarried and is so soft that an ax is used to trim off waste. The steel companies cannot use it in blast-furnaces, as much as 80% goes up the

stacks. Makers of ferro-manganese in electric furnaces can use it. The ore, as shipped, averages 39% Mn, and 12% SO₂. It is a flat deposit, covering a considerable area, known to be several hundred feet square. Some drill-holes show 40 ft. thickness. Surface overburden, one to two feet thick, is plowed and scrapped off.

LEADVILLE, COLORADO

Mining and Dressing Molybdenite at Climax.

A big mining project is now under way at Climax at the boundary-line between Lake and Summit counties and about 16 miles north-east from Leadville on the Colorado & Southern narrow-gauge railroad running to Denver. At this point the Climax Molybdenum Co. has been active for eight months erecting mining and milling plants and developing its mine on Bartlett mountain, where the greatest molybdenite deposit now known to exist in North America is situated. The entire mountain, whose peak rises to a height of 13,000 ft., is said to be ore averaging 1% molybdenite—a statement that renders superfluous an estimate of reserves.

The lode-rock is quartz-porphry and decomposed granite thickly foliated with molybdenite with a little iron pyrite.

A large and modern plant is now in operation. At present

MAP SHOWING SITUATION OF CLIMAX, COLORADO, AN IMPORTANT MOLYBDENITE DISTRICT.

all mining is being done through the upper tunnel on the south-western slope of Bartlett mountain overlooking Ten Mile creek from an elevation of 12,107 ft. This adit, running north-east, penetrates the mountain for a distance of 330 ft.; and, with the exception of a few feet near the breast, it is all in ore. Just inside the portal, two cross-cuts are driven at right angles and advance 400 ft. either way to the side-lines of the company's ground. Here they swing around in rough half-circles and return to the main adit at a point 750 ft. from the portal. These cross-cuts surround two solid blocks of ore 750 ft. long, 400 ft. wide, and approximately 370 ft. high, measuring 222,000,000 cubic feet. Ten cubic feet of ore equal a ton. The orebody is being stoped along the entire 800-ft. face extending on either side of the main adit. Chutes are being placed at intervals of 25 ft. with intervening pillars 50 ft. high between them. The first stope is now being carried up from these pillars on a width of 25 ft. and will be continued right through to surface. When finished, it will contain 740,000 tons of broken ore. It is planned to take 30 similar slices off the orebody.

The lower adit is 200 ft. lower down the mountain; it is 170 ft. long and 10 by 12 ft. in the clear. It is being equipped with heavy double-track and when it has reached its full length of 2200 ft. it will be fitted with an electric haulage system. This adit will be the main artery of the mine. At the present rate of development, 300 tons of ore is being extracted daily. Production will be increased to 1000 tons daily during the summer.

A Leschen tramway 4700 ft. long connects the mine with

the mill at Climax. The mill is the largest of its kind now operating in the United States. When it was erected last winter, it was stated to have a capacity of 250 tons daily, but in actual operation it handles 350 tons. The process used is a form of flotation. The ore is ground in ball-mills with oil and chemicals to 60-mesh. It is then put through a Dorr classifier, the oversize being carried off to another ball-mill for re-grinding. The fine is pumped into a series of Janney flotation machines, four 'roughers' and one 'dresser,' which catches the froth from the others. These machines are expected to remove the iron content. From the Janney machines the froth is pumped into a Callow machine, the concentrate from this box going to a second Callow for final separation. The finished product is pumped into two large settling-tanks, drained by a Portland filter, and sacked. The tailing from the No. 2 Callow is returned to the ball-mill with the oversize from the classifier.

The concentrate now being made averages 70% molybdenite and a small percentage of iron. At present it is worth \$2 per pound. To secure 1 ton of concentrate the mill must handle 130 tons of crude ore.

The erection and operation of the plant has been in charge of John H. White, as manager. He is assisted by James R. Welsh, mine superintendent; A. Ira Renick, mill superintendent; and G. O. Anderson, superintendent of construction.

With a shipment of 25 tons of molybdenite concentrate sent out on April 19, and another of 25 tons on the 30th, the Climax Molybdenum Co. had gross earnings last month amounting to \$304,000. The product was delivered to the Government at Pittsburgh, where it realizes \$2 per pound. The company has now produced 76 tons of concentrate. The manager reports that the mill is doing much better work. The first concentrate carried from 65 to 86% MoS₂; the second between 70 and 93%; the third was still higher, and it is believed that a 90% average concentrate will be produced in time.

The Molybdenum Products Co., which has erected its mill at Buffebur, a mile below Climax, to the north-west, is ready to begin operations. The company has developed a large deposit just east of the property controlled by the Climax Molybdenum Co., on Bartlett mountain. The ore is similar to that being extracted by the Climax people, carrying an average of 1% MoS₂. The mine is 1½ miles from the mill, the two being connected by a Leschen aerial tram. The mill has a capacity of 250 tons, and will be enlarged as operations continue. The company has erected a substantial and modern plant. An 80% product is expected.

Suits involving the title to large areas of ground in the Climax field, which are to be heard before the State Supreme Court in June, have held up work of the Pingrey Mines Co., the third big operator that has entered the molybdenite area. The company had completed plans for erection of the largest mill that has been put up in this field, and contemplated starting construction early in May. Considerable development has been done in several claims, where an immense tonnage has been opened. These plans were set aside temporarily until the legal tangle to some of the ground has been defined. The suit between Lake and Summit counties over the boundary line, a proceeding that makes uncertain the position of the Climax field with regard to county possession, has also aided in causing the company to abandon its plans.

HELENA, MONTANA

Labor Troubles Closing Mines.

Owing to a strike of stationary engine-men in the Helena district, four companies have ceased mining ore and are barely able to keep the mines from flooding. The men demanded an increase of \$1 per day, over that formerly paid, which was at the rate of \$4.50 per day. The raise was not

granted, but the demand had the effect of creating a desire on the part of miners to ask also for an increase over the present \$4 rate. One good gold producer, which has paid \$200,000 in dividends, has been closed indefinitely. This is the Thomas Cruse Developing Co.'s property in Scratch Gravel hills. It is developed on the incline to 640 ft., and laterally 1500 ft. It adjoins the Scratch Gravel Gold Co.'s holdings, which have been abandoned. Both mines are now filling with water, and nothing is said regarding the future of these two companies.

DULUTH, MINNESOTA

Early Operations on Mesabi Range.

Stripping is to start immediately at the Mace mine, between Keewatin and Stevenson, and it is planned to have a large force at work this summer. Butler brothers have the contract for stripping, and are now engaged in building camps near the site, and making necessary roads to aid in moving ground with all possible speed. It is not proposed to work the Mace as an open-pit mine, but stripping is for the purpose of opening a 'milling' pit east of the present shaft. Ore will be broken down in the pit and trammed to the shaft now in use. The Mace has never been a large producer, and there is not much of ore left in the mine, so it has a limited future.

A cave-in occurred recently at the Butler brothers stripping works. This caused some delay, but no men or machines were caught. Tracks for the waste-cars that were hauling from the big shovel are near the edge of the pit, resulting in the necessity of changing the tracks. Considerable time will be lost in doing this.

The Mississippi is the first mine in St. Louis county to start loading cars for the season of 1918. The cars are being loaded with ore that caved in the drifts and tramways during the time the mine has been idle. It will be stored at the docks at the head of the lake till navigation commences. It is not planned to stockpile any ore at this mine this spring, but to load all ore hoisted directly into cars. A large force will be put on immediately.

Work on the new 100-ft. concrete chimney at the Mississippi mine is about done. The last of the concrete was put on three weeks ago. The brick lining, which extends up for 30 ft., has been laid. It was expected that full power would be available soon. This would allow for the use of underground electric haulage, materially speeding-up work in the mine. Ore that is being removed from underground workings as clean-up work progresses is being loaded into cars. A large number are ready to ship to the docks. This mine will be one of the big producers among underground properties this season.

COBALT, ONTARIO

General News, and the Fort Matachewan gold district.

Lateral work has been resumed on the 1600-ft. level of the Temiskaming mine. This horizon has been recommended for exploration by Alfred R. Whitman, a leading geologist of this district.

The National Mines (formerly the King Edward) has resumed work, the 80-ton flotation plant being started a week ago. Results are fairly satisfactory.

The McKinley-Darragh-Savage has decided to resume work on the Savage section of its property, where there are from 10 to 12 acres of conglomerate formation as yet unexplored, and considered to have fair possibilities.

The Mining Corporation of Canada has made a second cash payment on a group of claims in the township of Rickard, on which encouraging deposits of gold-bearing quartz are being developed. This concern is maintaining its record in silver production, being ahead of any other silver mine under the British flag.

Elk Lake.—A fair rush of prospectors is taking place to the Fort Matachewan district, where encouraging discoveries of gold have been found in large sulphide dikes. Small mining equipments are being taken in for some properties.

PORCUPINE, ONTARIO

McIntyre and Newray.—Davidson and Ankerite.—Kirkland Lake Notes.

Porcupine.—The McIntyre company has acquired a controlling interest in the Newray mine, having taken an option on 51% of Newray shares at 45c. each. The McIntyre is to have a free hand in development and may either continue operations at the 400-ft. level, where an important development was recently made, or begin somewhere else. The Hansen vein in the Newray has been opened for 140 ft. on the 400-ft. level, assaying \$10 per ton. As the McIntyre is thoroughly acquainted with the mineralized zone traversing its properties, continuing into the Newray, the prospects for development of the latter into an important producer seem favorable.

The new 10-stamp mill at the Davidson is operating well. A high-grade orebody, 19 in. wide, was cut on the 100-ft. level. The main shoot has been opened for a length of 200 ft. Cross-cutting shows a considerable width of milling ore.

Arrangements have been made by which the Dome Lake mill of 200-ton capacity will test 1000 tons of ore from the West Dome mine. This may be preliminary to a permanent agreement for the treatment of the West Dome output.

At the Ankerite, being developed by the Coniagas company of Cobalt, a 12-ft. vein, stated to assay \$20 per ton, has been cut on the 275-ft. level.

Kirkland Lake.—The Wright-Hargraves has overcome successfully some trouble with water. A station has been cut on the 300-ft. level, where the width and grade of the ore is well maintained. The shaft is being sunk.

The new 60-ton mill of the Lake Shore is giving good results. Ore averages \$23 per ton.

At the Elliott-Kirkland, the rich ore opened at 425 ft. has been driven on for 100 ft., the vein maintaining its grade.

The Burnside shows rich ore at the 100-ft. level, where there is a 12-in. vein carrying over \$127 per ton, with low-grade ore on the wall.

Annual report of Tough-Oakes shows a net deficit of \$79,062. Total earnings were \$340,086, operating costs, \$364,847; and general expenses, \$54,300. Total deficit at the end of the year was \$198,290.

Mill of the Teck-Hughes during February worked 88.7% of the possible time, treating 2374 tons of ore, averaging \$7.27 per ton.

BAKERSFIELD, CALIFORNIA

Independent Oil Producers Meet.—Rise in Price of Oil.

On May 1 the Independent Oil Producers Agency, representing 175 petroleum companies, met here and was addressed concerning the situation by T. A. O'Donnell of the U. S. Fuel Administration. The annual report of the company for 1917 shows that 17,442,852 bbl. of oil was sold at an average of \$1.08 1/2 per barrel. The average price was much higher than in 1916, due to a new contract with the Union Oil Co. The year ended with a balance of \$117,796, against \$73,326 at the beginning. Oil stocks were 11,683,613 bbl. on January 1, 1918, a decrease of 429,772 barrels.

The Standard Oil Co. announces an advance of 25c. per barrel for crude oil at the well. The new schedule, effective May 1, ranges from \$1.23 for 14-gravity oil to \$1.57 for 37 and over. The previous range was from 95c. to \$1.32 per barrel. This rise was reflected in a general advance in the price of oil shares last week.

ARIZONA

Chloride.—The Schuylkill Mining Co. recently made final payment for the Tennessee mine. A mill is to be erected soon to dress all ore from the Tennessee and Schuylkill.

Kingman.—The Banner Gold Mining & Milling Co. is now putting in a compressor and other equipment. Contracts have been let for 350 ft. of development. Value of the ore increased in ground being opened on the 400-ft. level.

Mayer.—The Pocahontas mine is being re-opened. The present shaft will be sunk to the 500-ft. level and a mill erected to treat ore on the dump, taken from old workings.

Oatman.—The Gold Ore company is now treating 40 tons of ore daily at the Gold Road mill. Both companies are to treat ore in the same plant. The owners are erecting a crusher and Marcy mill at the mine. A pipe is to carry the coarse-ground ore to the mill, where tube-mills will reduce it further for cyanidation by the C. C. D. system.

The United Eastern output for March was 7980 tons valued at \$156,065, or \$19.56 per ton.

The Bald Eagle workings of the Tom Reed company are now connected with the Gray Eagle. The Bald Eagle orebody is to be explored by cross-cuts every 50 ft. Development will be continued in the eastern part of the Bald Eagle claim, where a cross-cut is being advanced to find the vein north of the fault. In order to mill the high-grade ore from the Bald Eagle changes are being made in the cyanide plant.

Pearce.—The Central Butte Mining Co. has just purchased a Chicago Pneumatic Co.'s oil-engine driven air-compressor to be erected on its property four miles south of this place. Development has shown a large body of low-grade copper ore.

Prescott.—Preliminary operations by the New United Verde Copper Co. at the old Logan mine have been so favorable that extensive development is planned.

The Arizona-Virginia Copper Co. has purchased 15 claims in the Castle Creek district from P. A. Johns of this city. Considerable high-grade ore had been mined by previous owners and Mr. Johns continued development, shipping several carloads. The new company is controlled by Colorado and California capital, and E. C. King, former superintendent of the smelter at Humboldt, is in charge. The property has been opened by three adits, approximately 500 ft. There is also a 200-ft. incline shaft and some stoping, making a total of about 900 ft. of work. Smelter records show that the 269 tons averaged 15% copper and \$1.50 silver, netting \$55 per ton after deducting all charges.

Superior.—The Magma Chief Copper Co.'s Watson tunnel is in 1900 ft., with 200 ft. to go. From the end a drill will bore 600 ft. farther, equal to a depth of 1300 ft. The tunnel recently passed through silver-bearing manganese.

Tombstone.—Phelps-Dodge Corporation is sinking a shaft at the Bunker Hill to determine the extent of the manganese orebody. A plant will be erected at Douglas to test this ore.

Tucson.—The Pima Mining & Smelting Co. has completed payments on the smelter at Socorro, New Mexico, and will move the plant to Tucson. A mine has been bonded in the

Dos Cabazos district, while another is to be secured. These are expected to ensure a supply of ore.

Molybdenum mines in this district are suspending work on account of market conditions.

CALIFORNIA

On May 7 the Industrial Accident Commission held a public hearing to consider amended tentative safety rules for gold dredges. These were prepared by the following: Harold Mestre (chairman), consulting engineer; F. L. Lowell (secretary), deputy mine inspector for Commission; L. D. Hopfield, of Natomas company; C. W. Gardner, of Hammon Engineering Co.; A. L. Wilde, of the International Brotherhood of Steam Shovel and Dredgemen; Carl Brown, of California Casualty Indemnity Exchange; R. L. Eltringham, electrical engineer for Commission; H. M. Wolfkin, mining engineer U. S. Bureau of Mines, chief mine inspector for Commission.

Carrville.—The boarding-house, warehouse, store, stock and fixtures, and six cottages at the asbestos mines on the south fork of Trinity river have been burned. The mines, owned by the Trinity Asbestos Mining Co., have lain idle for two years.

Ingot.—Five or six auto-trucks are hauling zinc and copper concentrates from the Afterthought flotation plant to the railroad at Bella Vista, 16 miles distant. One thousand tons was on hand when the roads opened after the rains.

Redding.—Material is arriving for construction of the

MAP SHOWING PRINCIPAL CENTRES OF SHASTA COUNTY, CALIFORNIA.

American Gold Dredging Co.'s boat across the river from Redding. The wooden hull will be 44 by 122 ft. Buckets are of 6 cu. ft. capacity. The wooden spud is 36 by 24 in. and 50 ft. long. The boat will be completed in 90 days after construction begins.

Winthrop.—The A. S. & R. Co., new owners of the Bully Hill mine, is making extensive improvements. The old smelter is being changed to a flotation plant. The first unit, for which machinery is on the ground, will have a daily capacity of 150 tons. The completed plant will have double

that capacity. A lodging and boarding-house, to accommodate 100 men, are being erected, also a club-room. Sixty men are employed in the mines; more are required. Daily shipments of ore to the smelter at Kennett are 115 tons.

COLORADO

Boulder.—Tungsten producers of this district met here last week to arrange for representatives to go to Washington to discuss price-fixing of tungsten and other minerals. About \$30 per unit is recommended for tungsten, which would increase production by a third.

Breckenridge.—Dredging has been started for the season. The French Gulch Dredging Co. was the first to begin. It is digging ground 38 to 45 ft. deep.—The Powder River Gold Dredging Co.'s new boat in Blue River valley is ready,

MAP SHOWING SITUATION OF BRECKENRIDGE, COLORADO.

only awaiting repairs to power line. Buckets are of 8-cu. ft. capacity.—The Tonopah Placers Co.'s three boats will soon resume. Gold recovered by dredging this year should be \$1,000,000, a gain of \$150,000 over the 1917 total.

Cripple Creek.—Gold production of the district in April totaled 104,500 tons, averaging \$9.59 per ton. Some of the milling records are as follows:

Mill	Tons	Value
Golden Cycle (Colorado Springs).....	29,500	\$21.00
Portland (Colorado Springs).....	6,000	20.00
Portland (Cripple Creek).....	38,800	2.04
Portland (Cripple Creek).....	7,900	2.30
Vindicator (Cripple Creek).....	20,000	1.96
Smelters	2,300	55.00

Eureka.—At the Sunnyside mine the U. S. S. R. & M. E. Co. is busy. For employees a bunk-house and club-room are being erected. The 16,000-ft. Trenton aerial tram is finished. At one point the cables are 500 ft. above ground. Storage-bins at the new mill will hold 3000 tons of the lead-silver-gold-copper ore. Marcy ball-mills crush the ore.

West Cliff.—The well-known Bull Domingo mine is again in commission. When silver was 50c. per ounce and lead 3.50c. per pound this mine produced \$1,500,000, mined from a depth of 1000 ft. In the same district are the Bassick and Geyser, two great producers of long ago. The former is opened to 1500 ft., the latter to 2800 ft., the greatest depth of any mine in Colorado. Ore carries silver, lead, and zinc. There are three large dumps estimated to contain 300,000 tons, which will be milled and are estimated to yield \$10 per ton, two tons concentrated into one. Besides the zinc orebody 30 ft. thick at the 550-ft. level there is a good quantity of lead, silver, and gold ore in the mine. The Bull Domingo has equipment capable of working to a depth of 3000 ft. The plant was formerly on the Geyser and is complete. Louis Wagner, well known in Colorado, financed the taking over by the Bull Domingo Development & Mining Co. and is general manager.

IDAHO

According to Robert N. Bell, State Mine Inspector, labor situation seems to be the only handicap in Idaho. All mines appear to be running shorthanded. New development is suffering in consequence, and all operations are being confined largely to ore production.

Kellogg.—The Bunker Hill & Sullivan smelter here is turning out 120 tons of refined lead daily and is working well.

The Douglas mine of the Anaconda company of Montana, on Pine creek, has resumed shipments of zinc ore after being closed during winter. There is said to be considerable ore blocked out and broken.

The Constitution lead-zinc mine near the Douglas is in good condition for production when the new railway is finished.

Sagle.—Preparations for mill construction are soon to be started at the Armstead mine on Pend Oreille lake. The initial unit will be of 100 tons capacity.

KANSAS

Treeco.—A 40-acre lease and developed mine near here has been sold by Playter brothers of Joplin, Missouri, to A. M. Brennan and others of Oklahoma City, Oklahoma, for \$150,000. A 400-ton mill is to be erected.

MICHIGAN

Houghton.—Franklin Mining Co. in 1917 had an income of \$1,048,303, of which \$792,527 was from copper sold. All charges totaled \$762,106. Surplus at beginning of year was \$192,094, and at end \$286,198. The superintendent, Enoch Henderson, reported that new openings covered 1916 ft., driving 1603 ft., costing \$6.998 per foot. Work north of the amygdaloid indicates ore of better grade with depth in that direction, and a large tonnage of better than average (10.3 lb. per ton) grade has been opened on No. 30 level north. On the conglomerate the best ore seems to be in the south. Ore stamped was 303,625 tons, yielding 3,155,574 lb. copper, and sold for 26.74c. per pound.

MISSOURI

Joplin.—Production of the Missouri-Kansas-Oklahoma region last week was 6406 tons blende, 45 tons calamine, and 1173 tons lead, averaging \$42, \$30, and \$80 per ton, respectively. Total value was \$368,206, making \$8,070,434 for 17 weeks. Oklahoma contributed ore worth \$258,454, and Kansas \$48,385.

The Tri-State Safety and Sanitation Association of Picher, Oklahoma, is endeavoring to ascertain whether or not the majority of zinc-ore producers of the Missouri-Kansas-Oklahoma region favor a selling organization of national scope.

MONTANA

Butte.—The Philadelphia shaft of Anaconda's Nettie mine is being deepened from 600 to 800 ft. This will help drain the Davis-Daly company's Hibernia mine.

Iron Mountain.—Intermountain Copper Co. has shipped 14 cars of concentrate valued at \$2200 per car. Developments at 400 ft. are good. Fifty men are employed. The mill works three shifts.

Troy.—Zinc concentrate, carrying 30 to 36% metal, is being shipped regularly by Snowstorm Mines Consolidated, from mill and accumulations. Ore sent to the mill up to 300 tons daily—is receiving closer sorting. No. 7 tunnel, to open the vein worked on the other levels, is in 700 feet.

Arguments were made at Missoula recently in the case of Edward McCaffrey, of Spokane, against Harry L. Day, brought to have a contract rescinded for the purchase of the Big Eight mine by Mr. Day. This mine is near the Snowstorm. About 2000 ft. of work has been done, showing zinc-

lead ore. The deposit was discovered many years ago by eight men, from whose number and stature its name was derived.

NEVADA

Las Vegas.—It is reported that Thomas Thorkildsen of Los Angeles has purchased the interests of the Manganese Association for \$100,000 cash. The deposits are 16 miles south-east of Las Vegas, and were leased from B. R. Jefferson, R. N. Edwards, R. W. Martin, W. E. Ferron, and J. F. Marrs to James McCoy, J. O. Gillice, and W. H. Connor.

Midas.—Elko Prince company has paid 5c. per share, equal to \$50,000. This is No. 3 dividend.

Mina.—A 100-ton concentrating plant will probably be built at the Gunmetal tungsten mine, 23 miles east of this place. Deposits consist of a large low-grade body, also an 18-in. vein of high grade. Fritz Elges and others are financing the work.

Palisade.—Union Mines Co., south of this place, has opened a large quantity of ore on its 700-ft. level. As soon as conditions permit a large mill is to be erected. Shipments are being made to smelters in Utah. Senator Thatcher is manager.

Virginia City.—Union Consolidated from November to March, inclusive, mined 8054 tons of \$26.56 ore, also 1988 tons averaging \$9.25 per ton. Returns totaled \$230,000, of which \$60,000 was paid in six dividends and \$40,000 of debts.

From the 2300-ft. level of the Mexican, 42 tons of \$28 ore was milled last week.

OKLAHOMA

Picher.—The Eagle-Picher Lead Co. started operations in this field on March 15, 1916. At present it has some of the best mines in Oklahoma, and 3 modern mills at work. In the Netta mill flotation is employed with jigs and tables. A. E. Bendelari is general manager.

OREGON

Medford.—The Blue Lodge copper mines, which suspended shipments late last winter, will resume. It is probable that 40 motor-trucks will be engaged in carrying 300 tons of ore each day from the mine to railroad this summer. Seventy-five miners have been employed all winter opening ore for these increased shipments. The Copper King, Bloomfield, and other groups being operated from the Blue Lodge district will also be heavy shippers.

Perry.—Extensive deposits of chrome near here, in Union county, have been acquired by A. L. White, W. J. Nicholls, and other Spokane men. A concentrator with a daily capacity of 75 tons is being built. It is expected to be ready within 60 days.

UTAH

Alta.—Samples taken from the lowest point in workings below third level of the Emma mine assayed 186 oz. silver and 58% lead.

South Hecla Mining Co. reports that during 1917 there was 1309 ft. of development performed, costing \$13,234. Total openings amount to 27,846 ft. Work last year was mostly to the Wedge vein, from 250 and 400-ft. levels. Production was as under:

	Company	Lessees
Ore, tons	3,797	727
Gold, ounces	128	37
Silver, ounces	65,268	11,516
Lead, pounds	607,794	104,102
Copper, pounds	21,035	8,023
Zinc, pounds	361,964	85,682
Net profit	\$27,788	
Net profit from lessees	3,019	

Property is well equipped. Efforts last year were mainly devoted to extracting smelting ore. Milling ore is to be exploited in 1918.

Gold Hill.—Western Utah Copper Co. is opening good ore on its 400-ft. level. Daily shipments are from one to two cars. More miners are being employed.

Recent developments in the Frankie mine of the Woodman company have been good. Above the adit there is 8 ft. of 5 to 8% copper ore.

The Undine mine has shipped some 10% copper ore, carrying gold and silver. In the past this property was a good producer.

Garrison Monster is to erect a compressor, hoist, and use drills. Shipments carry from 10 to 15% copper. Some lead-silver ore is also being mined.

Lessees at the Union claim sent 7 to 10% ore to smelters.

Goldstrike.—There is said to be considerable work under way in this district, principally on the original claim, the Hamburg of the Bull Valley Gold Co. Lessees are driving an adit, also sacking some ore. Other properties are the B. & B., Goldstrike-Virginia, Banker, and Goldbug.

Park City.—The Ontario Silver Co. is to sink on ore from 1700 to 2000 ft. This will be a winze 70 ft. from the shaft. The company's financial position is good.

Tintic.—On May 27, five companies owning 500 acres in the south part of the district are to discuss consolidation. It is proposed to merge the Diamond Con., Southern Queen Gold, West Morning Glory, and Homestake into the Laclede Mining Co. On the Laclede a shaft is taken down 500 feet.

Centennial-Eureka has opened 35% lead, 100 oz. silver, and \$10 gold ore on its 1900-ft. level.

The Gold Chain mine at Eureka has been re-opened after a short shut-down due to labor conditions.

The Copper Leaf company is sinking below the 500-ft. level.

The Mammoth mine has been closed, as the men refused to work unless paid twice a month.

VIRGINIA

Montebello.—Tin deposits near Irish Creek, Rockbridge county, are described by H. G. Ferguson in Bulletin No. XV-A of the Virginia Geological Survey, at Charlottesville. The district is in an isolated part of the Blue Ridge district,

PART OF VIRGINIA, SHOWING SITUATION OF TIN DEPOSITS ON IRISH CREEK.

Irregular hills and ridges, altitudes from 2000 to 3500 ft. Cassiterite was identified here in 1846. Some work was done in 1883 to 1885 by two companies. About 290 tons of 3.3% tin ore was mined but not shipped. In 1889, Boston people obtained an option and built a mill costing \$50,000. About 2400 lb. of 43% concentrate was shipped. Litigation stopped work from 1893 to 1918, the title being un-

certain. Cassiterite is found in quartz veins that cut the hypersthene grano-diorite and in the adjacent altered grano-diorite. Deposits also contain arseno-pyrite, pyrite, siderite, wolframite, scheelite, muscovite, fluorite, and beryl. The arseno-pyrite is said to carry considerable gold and silver. Cassiterite assays 63.583% metallic tin. The veins are probably not continuous for long distances, but this is certain owing to lack of development. It is concluded that the district offers some hope of reward for systematic exploration of the discovered veins, and possibly other deposits may be found on the area of hypersthene grano-diorite. Presence of a greisen-like alteration product of grano-diorite is the best indication of tin, and everywhere appears to accompany the tin-bearing veins.

WASHINGTON

Chewelah.—The United Copper Mining Co.'s mill is now dressing 500 tons of ore daily. On 1300-ft. level the ore-body is 15 ft. wide, carrying 2½% copper and 8 oz. silver per ton. This is over a length of 240 ft. Eighty men are employed, but there is room for forty more.

Laurier.—Chrome has been found just across the border from here in British Columbia by Cameron, Myers, and others of Laurier. The Laurier copper mine is 5 miles south-west of this place.

Loon Lake.—This copper district is reported to show increased activity. Development has been confined to four properties. The Loon Lake Copper Co. has opened ore to depth of 500 ft., shipped considerably, paid dividends, and is to erect a 100-ton mill. This company has issued bonds for \$40,000 for new plant. Judge George Turner of Spokane is president. The Jumbo shaft is down 100 ft. The Loon Lake Bluebird Co. is sinking to 200 ft., and plans extensive work.—The Spokane Copper Co. is sinking and is to erect larger machinery.

Northport.—The Electric Point company has proved the downward extension of an ore-chimney to the 700-ft. level. The ore is still a lead carbonate, but a change to the sulphide is expected at water-level. The 2½-mile aerial tram will soon be erected.

Valley.—The Valley Magnesite Co. has contracted for

MAGNESITE DEPOSITS IN WASHINGTON ARE NEAR CHEWELAH AND VALLEY.

delivery of 2000 tons of calcined magnesite per month until the end of the War and for not less than a year. The plant is to be improved to the extent of \$200,000 during 1918.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

L. D. Kitch was at Ajo this week.

Albert Burch has returned to San Francisco from Cuba. **A. Doyle** is in the 27th Engineers at Camp Meade, Maryland.

Howard D. Smith has returned to San Francisco from Nevada.

Karl Eilers has been in San Francisco on a tour of inspection.

Robert E. Kinzie has returned from a journey of inspection in Nevada.

Walter Harvey Weed is in San Francisco on his way from Arizona to Montana.

Benjamin Rezas has left the Colorado Mining Co., P. I., and will go to Burma.

William C. Madge has arrived at Seattle, on his return from Siberia to Butte.

Thomas F. Cole is at Los Angeles, on his way to Butte, after a visit to Ajo, Arizona.

J. M. Callow has been here on his way to Salt Lake City after a tour in the South-West.

Ernest Hibbert of Nickelton, Ontario, was in San Francisco, on his way to Miami, Arizona.

Edwin E. Chase and his son, **R. L. Chase**, have gone to Baker City, Oregon, to examine a gold mine.

Scott Turner has received a commission as Lieutenant (senior grade) in the line, U. S. Naval Reserve Force.

Sidney J. Jennings was here this week, on a visit to the properties of the U. S. Smelting, Refining & Mining Co.

J. H. Mackenzie has gone to Washington to give his services to the Bureau of Mines in mobilizing the tungsten output.

A. J. McGregor, of South Porcupine, Ontario, is on his way to Nicaragua, as surveyor and assayer for the Chontales Mines, Ltd.

Harry Franklin, engineer for the Las Quebradas Mining Co. of Central America, is in San Francisco this week on his way to New York.

H. D. Satey, Pacific Coast representative of Halcomb & Davidson, Inc., makers of mine drill and tool-steel, is in New York for three weeks.

Edgar A. Collins, superintendent of the Ridder mine, in the Altai, has returned safely with his family from Siberia, and is now at Ben Lomond, California.

Samuel Cohen has resigned from the management of the Crown-Reserve company at Cobalt, Ontario. He is succeeded by **Harry Stewart**, formerly assistant manager.

Charles R. Keyes, consulting engineer, of Des Moines, has been chosen by the Democratic party of Iowa as candidate for the United States Senate, to succeed Senator **W. S. Kenyon**, whose term soon expires.

C. M. Eyc, superintendent for Benguet Con. Mining Co. at Baguio, P. I., is spending his vacation in China and Chosen, with headquarters at Shanghai, in care of the American Consulate. He expects to return to the Philippine Islands by July 1.

J. Parke Channing, chairman of the Engineering Council, has appointed the following Committee on Patents: **Charles A. Perry** (chairman), **C. A. P. Turner**, **Corydon T. Purdy**, **Horace V. Winchell**, **Edwin J. Prindle**, **David S. Jacobsen**, **Frank N. Waterman**, and **J. Parke Channing**. This committee will investigate reforms in the United States patent system and in the use of experts in litigation, co-operating with similar committees of the National Research Council and the technical societies.

THE METAL MARKET

METAL PRICES

San Francisco, May 7

Aluminum-dust, large and small lots, cents per lb.	65-70
Antimony (wholesale) cents per pound	13 1/4
Copper, electrolytic, cents per pound, in carload lots	23 1/2
Copper, electrolytic, cents per pound, in small quantities	24 1/2
Lead, pig, cents per pound	7 1/4-8 1/4
Platinum, pure and with 10% iridium, per ounce	\$108-\$116
Quicksilver, per flask of 75 lb.	\$110
Spelter, cents per pound	9 1/2
Zinc-dust, cents per pound	17 1/2

ORE PRICES

May 7

Antimony, 45% metal, f.o.b. California, per unit	\$110
Chrome, 38% and over, California, per unit	\$1.25-\$1.50
Manganese, 40 to 50% Mn, Hazen, Nevada, cents per unit	92-110
Manganese, 48%, New York, per unit	\$1.20
Tungsten, 60% WO ₃ , California, per unit	\$24
Molybdenite, per lb., 85% MoS ₂	\$1.80

EASTERN METAL MARKET

(By wire from New York)

May 7.—Copper is unchanged. Lead is quiet but steady. Spelter is firm and higher.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.67c. for small lots, effective until June 1, 1918. Quotations in cents per pound are as under:

SILVER

Below are given official (no Government) quotations, in cents per ounce of silver 999 fine. In order to get prompt settlements, apparently with smelters and others, sellers allow a discount from the Government price of \$1, hence the lower price.

Date	New York, London, etc.	Average week ending

Melting of silver dollars commenced at the New York Assay office on April 20. Its daily capacity is up to 600,000 dollars, equal to 515,210 ounces of silver, plus the copper alloy in the coin.

Discussing the future of silver, the "Boston News Bureau" considers the price established but not fixed at \$1 per ounce. While the Pittman silver bill is popularly supposed to fix the price at \$1, the question has been raised whether this is not a minimum, and that no limits have been placed on a maximum price. The law as passed does not commandeer the output of silver, neither in the mint nor anything in the law or any agreement between the silver producers and the Government that the mining companies shall sell to domestic consumers at the same price as to the Government. In this respect the silver situation is different from steel and copper. Officials of the mining companies say that no agreement has been made whereby their entire output or any specific proportion of their output is to be turned over to the Government. The Pittman bill enables the Government almost immediately to come into possession of 350,000,000 silver dollars, and while these may be melted and exported as fast as they are, certificates can be withdrawn, and the dollars so melted are to be replaced, there is no time limit placed on the re-coining.

Following is the text of the purchasing section of the Pittman Silver Bill (S. 4292) as it passed Congress:

Section 2. That upon every such sale of bullion from time to time the Secretary of the Treasury shall immediately direct the Director of the Mint to purchase an amount of silver equal to 37.25 grains of pure silver in respect of every standard silver dollar so melted or broken up and sold as bullion. Such purchases shall be made in accordance with the then existing regulations of the Mint and the fixed price of \$1 per oz. of silver 1000 fine, delivered at the option of the Director of the Mint at New York, Philadelphia, Denver, or San Francisco. Such silver so purchased may be

re-sold for any of the purposes hereinafter specified in Section 3 of this Act, under rules and regulations established by the Secretary of the Treasury, and any excess of such silver so purchased over and above the requirements for such purposes shall be coined into standard silver dollars or held for the purpose of such coinage. The net amount of silver so purchased, after making allowance for all re-sales, shall not exceed at any one time the amount needed to coin an aggregate number of standard silver dollars theretofore melted or broken up and sold as bullion under the provisions of this Act, but such purchases of silver shall continue until the net amount of silver so purchased, after making allowance for all re-sales, shall be sufficient to coin therefrom an aggregate number of standard silver dollars equal to the aggregate number of standard silver dollars theretofore so melted or broken up and sold for bullion.

Commenting on the silver situation as at April 11, Samuel Montagu & Co. of London say that the drawing rates of the Indian Council have been advanced one penny (two cents) as a consequence of the Silver Bill passing Congress. If the Indian government is in a position to secure a large proportion of the United States government silver, it will be placed in a very strong position as to the currency problem. Unless the British government has arranged with the American government for these silver transactions, a rate of exchange differing from that which has obtained during the last two years, the cost of the silver content of the rupees purchased at \$1 per ounce 999 fine (so far as those required for British trade are concerned), will be 1s. 5.35d., to which shipping expenses, etc., from the United States to India have to be added. The equivalent in sterling (British currency) of dollar silver is 46.6d. per standard ounce, calculated at the current exchange rate.

LEAD

Lead is quoted in cents per pound, New York delivery. Government metal receives 7c. per lb. until August 6.

May	7.38	10.29	7.07
June	6.88	11.74	7.55

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. In February 1918 the Government fixed prices for grade A spelter at 12c. per lb. for itself and the open market. This grade constitutes only a small proportion of the total output. Lower grades can make their own prices as usual. Sheet-zinc is fixed at 15c. per pound.

June	12.85	9.63	7.84

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking 40% of the United States quicksilver output, paying therefor \$195 per flask. Outside of this business the competitive market can make any price as usual. Prices, in dollars per flask of 75 pounds:

Eastern Metal Market

New York, May 1.

Interesting news features are not prominent while marked inactivity continues as at present. The markets are all quite lifeless.

The copper market waits now on the decision this week concerning the fixed price to be effective after June 1.

Tin prices are at unheard-of levels for all positions, and buying is at a standstill because of lack of offerings.

Lead is declining and is very quiet.

Zinc is a little stronger and somewhat steadier.

Antimony has firmed slightly.

The most momentous development of the War affecting the steel industry was the pledge of all the leading steel-makers of the country, given at New York last week, to the director of steel purchases, J. L. Replogle, that they would operate on Government orders to the exclusion of commercial business. The Washington view is that the amount of steel that must be delivered in the next few months to the Government, its Allies, and all domestic industries engaged in war and similar work, has been under-estimated in the industry which quickly agrees that a 100% operation is the only convincing answer. Some producers think that a 60-day concentration on Government orders will make it possible to resume general business to some extent, but the War Industries Board does not encourage this view. The plan is to hold the steel men strictly to their pledge, and a close check will be kept on all deliveries to individual account.

COPPER

There is practically no change in the situation, and the trade is marking time, with interest concentrated in the meeting today and later this week in Washington between copper producers and the War Industries Board to discuss the price of copper that is to obtain after June 1. Speculation is quite free as to the outcome, but of course no one knows the result. Many are confident that there will be no lowering of the 23.50c. level, and some feel sure that it will be advanced to 25c. It is recognized that the supply in the shape of production must be kept at the maximum if the present enormous needs are to be met. Whether a price-advance is necessary to do this must be decided this week. Six important companies report 14.7% decrease in output for March as compared with the same month in 1917. Others show a substantial increase. Exports are declining. Those for March are reported as 22,556 tons, not including those to Canada. An estimate, including Canada, puts the exports for the first quarter at 93,447 tons, which compares with 134,805 tons for the first quarter of 1917, or a decrease of about 32%.

TIN

Some anxiety was apparent late last week when the announcement appeared that Holland had placed an embargo on shipments of Banca tin. This is denied, but the real facts are not known. It is regarded as probable in the trade, however, that the metal will be permitted to come forward under license, the same as British tin. It is pointed out now that the Holland tin trade is too important and valuable to Holland to be entirely cut off. In England it is evident that some new regulations in the tin situation are on foot, but it is more or less uncertain what they are. Thus far it is sure that one cannot buy or sell tin except by first getting a Government license, and this may eventually mean complete control, which thus far has not existed. The market is quiet and offerings are scanty, resulting in a dull situa-

tion. Buyers are getting on the anxious-seat, and the situation is not reassuring. Prices continue to advance, both here and elsewhere. Spot tin is unobtainable, but is now quoted nominal at 95c., New York, with higher prices reported as having been paid for little lots. The London market keeps going up. Yesterday spot Straits was quoted at £361 per ton, an advance of £18 per ton since a week ago. These are unheard-of prices. Arrivals to April 23, inclusive, are reported to have been 480 tons, with 5000 tons estimated afloat.

LEAD

General conditions are unchanged from those prevailing last week. Most large producers are well sold up for May, and the market is still not quite equal to taking all the lead offered by smaller interests. The large Western producer has adjusted his labor troubles and is again in operation. The market is quiet and dull, with the tendency downward. Buying has been and is scant, and offerings are moderate in quantity. There are both bullish and bearish factors in the situation, with the latter at present the determining ones, but a revival of demand would at once result in a strong market. Spot lead is quoted and sold at 7.12½c., New York, but not actively. The American Smelting & Refining Co. has not changed its quotation of 7c., New York, but it may do so any day, for the outside market is now 6.80c., New York, and 6.62½c., St. Louis.

ZINC

The market is stiffer and stronger and has a firmer undertone than for the last two or three weeks. Consumers are displaying a little more interest, but it is not marked. Prime Western for early and May delivery is quoted today at 6.75c., St. Louis, or 7c., New York. On Thursday it sold at 6.70c., St. Louis. For futures 6.80 to 6.85c., St. Louis, has been obtained.

ANTIMONY

A somewhat better demand, both Government and domestic, has slightly strengthened the market, which is now quoted at 13 to 13.25c. per lb., duty paid, New York, for Chinese and Japanese grades for prompt and early delivery. Some believe the bottom has been touched.

ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is officially controlled at 32c. per lb. for 50-ton lots with lots of 15 to 50 tons fixed at 32.10c. per lb., and of 1 to 15 tons at 32.20c. per pound.

ORES

Antimony.—The quotation is unchanged at \$1.75 per unit. There is no interest on the part of buyers.

Ferro-manganese.—All importers here of British ferro-manganese, and some consumers, have protested individually against the Government order to prohibit imports after May 13. A modification of the order is hoped for. Imports in March were 3555 tons, which is more than those for January and February combined.

Molybdenum. Buyers are scarce, and offerings of molybdenite at present are not obtaining takers.

Tungsten.—The market has not been active. Quotations are unchanged at \$24 per unit in 60% concentrates for high-grade wolframite, and \$24.50 for scheelite, with off-grade ores bringing a correspondingly lower price. Ferro-tungsten is bringing about \$2.25 to \$2.35 per lb. of contained tungsten.

Book Reviews

Handbook of Hydraulics. By Horace W. King. Pp. 413. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, \$3.

This book will be particularly valuable as a reference book for the practising engineer, although it will also be useful for the student. The opening chapters deal with hydraulic units and the fundamental principles of hydrostatics. Following this, the flow of water through orifices, over sharp-crested weirs and weirs not sharp-crested, through pipes, and in open channels is discussed in order. The next chapter considers methods and instruments for measuring water, and the preparation of discharge-records and expected storage-curves. The final chapter of the text deals with various special problems. There are two appendices, one on the comparison of weir formulas with experiments, and the other on the comparison of the Kutter, Manning, and Bazin formulas with the experiments recently made by F. C. Scobey of the U. S. Department of Agriculture. An unusually complete set of tables is included, comprising practically every mathematical table that the hydraulic engineer might need. There are also a number of diagrams and other illustrations.

Useful Minerals and Rare Ores. Second edition. By Alexander McLeod. Pp. 254, index. John Wiley & Sons, New York, 1917. For sale by 'Mining and Scientific Press.' Price, \$1.75.

In these times, when the search for all minerals, especially the rarer ones, is so keen, a pocket manual giving the simplest tests is a necessary companion. The book before us is thoroughly practical. We remember the first edition, and found it useful; the second is much better. A small outfit of apparatus and chemicals, combined with a fair knowledge of ore occurrence and common-sense, is all the prospector and student needs. As secondary enrichment of orebodies is of such great importance, 24 pages are devoted to this subject following prospecting hints. The preliminary examination of the minerals and metals covers 100 pages, this followed by the remainder of the book describing physical and other simple tests for identifying metals and ores. A few pages are devoted to gems. Additional identification tests include soda on the charred rod, streaks, minerals that fly to pieces when laid on glowing wood, and when heated in a glass tube closed at one end, and minerals that contain volatile elements which cover a glass tube with a coating. We do not hesitate to recommend this practical little treatise to all interested in the mineral industry.

Petroleum Geology of Wyoming. L. W. Trumbull. Pp. 78. Ill., index. G. G. Bovee, Cheyenne, Wyoming. For sale by 'Mining and Scientific Press.' Price, \$5.

This book contains the first comprehensive discussion of the subject that has been published. Hitherto, although a considerable part of the data contained in the present volume had been published, it was scattered through a number of Federal and State geological reports, while a good deal of it has never been published. The author is State geologist of Wyoming. The first part of the book is devoted to the geological history of the State, with particular regard to the oil-bearing horizons. A brief description is then given of each of the various oilfields, both producing and prospective. Geological sections are shown for the principal fields, as well as a number of well-logs. Land titles are discussed,

also methods of leasing the State school-lands. There is an insert map of the entire State on a scale of about 20 miles to the inch, showing the principal geological features. The book contains a number of attacks on the policy of the General Land Office and other Federal officials, which, while perhaps excusable in a newspaper article, are, irrespective of the merits of the case, entirely out of place in a book of this character. The book will be of value to people directly interested in oil-development in Wyoming. Its usefulness would, however, have been materially increased if a chapter or two had been added regarding drilling and operating conditions in the various fields.

Relief From Floods. By John W. Alvord and Charles B. Burdick. Pp. 169. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, \$2.

The curve of damage from floods in most countries shows a general tendency to rise and is likely to continue to do so unless more energetic and more intelligent measures are taken for flood-control. The present volume is particularly valuable as indicating what such measures should be. While many of the illustrations are naturally drawn from conditions in Ohio, with which the authors are most familiar, the general principles are equally applicable to flood-control problems in other parts of the world. The first chapter discusses damage from recent floods and the records of floods on different streams. Little credence is given to the popular belief that floods are increasing either in size or in frequency, or that deforestation, except in a few special cases, has much to do with increasing flood-volumes. The next chapters are devoted to methods of investigating flood-control problems and of predicting future floods from past records, particular attention being paid to the formulas developed by W. E. Fuller based on the ratio between average floods and the floods that may be expected once in a given period of years. The next chapter deals with channel improvements for protection against floods, including cut-offs, channel enlargement, and the construction of levees. The final chapter discusses flood-control by water-storage. There are a number of useful tables and diagrams included.

Popular Oil Geology. By Victor Zeigler. Pp. 144. Ill., index. C. H. Merrifield, Golden, Colorado. For sale by 'Mining and Scientific Press', San Francisco. Price, \$2.50.

This book is based on a series of lectures recently delivered by the author, who states in the preface that it is not intended for the experienced oil geologist but rather for the man without technical training in this branch of geology. Writing a book on a technical subject for the non-technically trained reader is a difficult task. There is always danger either of explaining too much or not explaining enough. Thus the present author in discussing capillary pressure states that it is a function of the surface-tension of the liquid although it is probable that any reader who needed to have capillary pressure explained to him would stand in even greater need of a definition of surface-tension, and, for that matter, of function as well. Such shortcomings, however, are relatively unimportant, and the book as a whole should be valuable for the class of readers for which it is intended, particularly those who are interested in either the Colorado or the Wyoming oilfields. The first chapter is devoted to general history and statistics of the petroleum industry. The next discusses the physical and chemical properties of oil and gas, following which is a brief discussion of the various theories of the origin of oil and gas. Several chapters are then given to a discussion of those geological phenomena that affect the migration and accumulation of oil, and to the application of a knowledge of these

phenomena to prospecting for oil. A chapter is devoted to oil-shale, and one to oil investments.

Chemical French. A study of French chemical literature. By Maurice L. Dolt. Pp. 398, index. The Chemical Publishing Co., Easton, Pa., 1918. For sale by 'Mining and Scientific Press.' Price, \$3.

The Chemical Publishing Co. has done the English-speaking world a service by bringing out a book that will assist students to the correct interpretation of French chemical literature. It begins with the old-fashioned method of the acquisition of a language, with vocabularies and exercises which, however, rapidly introduce the words that are in common use in technology, so that before the student will have gone through more than 32 pages, he will have begun to use the language of the French chemist and will be fitted to proceed to an understanding of such subjects in the French language, if accompanied by parallel study in the grammar or in some other work for learning the fundamentals of the idiom. The student will especially appreciate the glossary, which is in reality a little dictionary of 74 pages, giving the words that are necessary in reading chemical literature. We welcome the book for another reason. The time has passed when students from the United States will go to Germany to acquire their training in technology. It has been recognized at last that the German training, although a minutely exact one, is lacking in those features that strengthen the constructive powers. We realize, now that we are able to see Germany more clearly with the mask torn off, that the great advance in the development of chemical theory has been made by the French, the English, the Americans, the Italians, but not by the Germans. We have discovered that treasures of scientific investigation are locked up in the French language, and that the greatest progress in the study of chemistry, with a view to its further development, is to be obtained by absorbing the fruits of the work of the great French investigators.

American Lubricants. From the standpoint of the consumer. By L. B. Lockhart. Pp. 236, ill., index. The Chemical Publishing Co., Easton, Pa., 1918. For sale by 'Mining and Scientific Press.' Price, \$2.

The present war has been termed as one of applied science, in which gasoline and lubricants play extremely important parts. Lubrication of rapid or slowly-moving machinery requires more skill than is generally supposed, whether it be a watch, 10,000-kw. turbo-generator, or planing-machine. It is essential that an engineer know the grade of oil he is using, its viscous nature, also from what base oil it was made. In this book he will find such matters discussed practically; also many tests on a variety of lubricants. Grease is used in increasing amounts for lubricating heavy machinery, also even for moderate-speed shafting and inaccessible parts. Graphite and mica are often mixed with grease to advantage. Animal and vegetal oils find a place in many plants, and are described. With the enormous expansion in the use of automobiles and internal-combustion engines, lubrication requires much study, but in this case the consumer of oil need not bother much, as the manufacturer has designed the system to take care of the high temperatures produced. Lubrication of electrical machinery, steam engines and locomotives, cotton mills, and the like, receive due consideration. Stress is laid on the fact that railroad and power-plant companies, which allow a fixed quantity of lubricants for the machines in use, make a costly mistake in so doing, as often their engine-men need oil badly and cannot get any. Seven short chapters on specifications for oils, and various tables conclude a book for every consumer of lubricants.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

BURT OIL FILTRATION

In the Burt oil filter, 'unit type,' the dirty oil enters the waste-oil receptacle (see sectional cut) and passes through the small perforations, flowing thence horizontally to the two filtering cylinders, and in passing to these cylinders the heavy impurities fall by gravity into the sediment pan, and therefore do not clog the filtering cloths or filtering material. Each cylinder is wrapped with a cloth through which the oil must pass before entering the filtering cylinder. After

the dirt and grit falls into the sediment pan. Those acquainted with other makes of filters will understand the advantage of this. In other filters the bulk of the sediment is at the bottom of the filter instead of at the top. When it is at the top it can be removed readily without interfering with the supply of pure oil for the oiling system. Owing to the effect of the hot-water chamber at the top, the Burt oil filter, 'unit type,' will filter from 50 to 75% more oil than any other style occupying an equal amount of space. This filter will handle successfully the heaviest grades of oil,

INSTALLATION OF 'UNIT' OIL-FILTER IN MT. VERNON STREET POWER-HOUSE OF PHILADELPHIA RAPID TRANSIT COMPANY

going through a quantity of bone-black, the oil passes downward through the two tubes into the bottom of the filter. By means of plates attached to the bottom of the tubes, the oil is spread in a thin film and is thoroughly washed by the water. Any impurities remaining in the oil drop to the bottom of the filter and can be flushed out at any time by opening the gate-valve, which connects with the sewer.

The hot-water chamber in the upper part of the Burt filter is an important detail. It is found only in the Burt style, and is covered by patent. The object in heating the oil before filtering, is to cause it to flow more freely, thus increasing the speed of filtration and the filtering capacity. When the dirty oil is heated, it spreads out, and most of

such as lard, crank-case, gas engine, cylinder, and other kinds. The heating arrangement will make the heaviest grade of oil flow freely and filter easily. Hence, it is hardly necessary to say that the Burt will filter common engine or machine oil to perfection.

The 'unit' filters are so constructed that they can be used with or without an oiling system, a feature which should have full consideration by every prospective buyer of an oil filter. The latest engineering practice indicates that within a few years almost every power-plant of average size will be equipped with an oiling system of some description. The 'unit filters' can, if desired, be installed and operated at first without being connected to an oiling system, and if,

later on, an oiling outfit is added to the plant, pipe connections can be readily made to the filter without extra expense. In cleaning the Burt filter, 'unit type,' it is not necessary to shut-down the whole system and disconnect the piping. If more than one unit is used, all that is necessary is to shut off the flow of oil to the filter to be cleaned, allowing the other filter to handle an extra amount. Where only one filter is installed, the cleaning operation is simple. The cloth around one cylinder can be removed instantly, and if the filtering material also needs to be removed, unscrew one cylinder and screw a plug, which is furnished for that purpose, into the tube, so as to keep the dirty waste-oil from flowing into the filter. The other cylinder will continue in

changing the pipe-connections. The water in the bottom of the three units can be drained into the sewer by opening one valve, and the supply of pure oil can also be regulated by one valve. Any number of filters can be placed in a row or in any position desired, and the piping arranged accordingly.

Among recent installations of 'unit filters' for use in connection with steam turbines may be mentioned those for the De Laval Steam Turbine Co., Trenton, N. J.; The B. F. Goodrich Co., Akron, O.; Diamond Rubber Co., Akron, O.; New Orleans Railway & Light Co., New Orleans, La. (2); Bahia Electric Tramway Co., Bahia, Brazil; De Beers Cons. Mines Ltd., Kimberly, South Africa; Syracuse Lighting Co., Syracuse, N. Y.; Columbia Electric Railway, Light & Power Co., Columbia, S. C. (2); Fort Wayne & Wabash Valley Traction Co., Fort Wayne, Ind. (3); and many others, names of which will be cheerfully furnished upon application.

DISTILLATION OF LIGNITE

Efforts are being made in France to introduce the distillate of lignite for tars. The Societe de Distillation des Combustibles, Paris, is constructing an improved Ziegler type of furnace similar to that used for the distillation of peat, a type yielding about 7% of tar which is treated by fractional distillation carried out 'in vacuo,' to increase the output of heavy products; followed by chemical purification by washing with dilute sulphuric acid and soda, to remove the picolines, cresols, and other products. The crude paraffine, extracted by crystallization of the heaviest oils, is first passed through the filter-press. The purification consists of a series of filterings in the filter-press, and meltings in the light oil. The last traces of oil are removed by scrubbing with super-heated steam, and the paraffine wax is clarified by filtering through animal black. In one place in Germany, where the system was adopted, 70 to 80% of marketable products was obtained from lignite tar, namely, 15 to 20% paraffine wax, 5 to 20% kerosene; 5 to 15% of cresotes and organic acids; the remainder being light products, petrol, etc., or heavy products such as gas-oils and lubricating oils. Concurrently with the great interest taken in the development of the shale-oil industry in America, it is worth while to consider the possibility of utilizing the large deposits of low-grade lignites for another set of greatly needed chemicals, including the fixed nitrogen which can be converted into ammonium sulphate. Among the available products are benzol and toluol, and the gas can be employed in many places for industrial purposes.

The Asbestos Protected Metal Co. of Pittsburgh, effective on May 1, 1918, will be known as the Aspromet Company. When this concern was established in 1905, its sole product was asbestos protected metal. The initial product met with such universal favor that it resulted in complementing this by adding other articles to their other lines of building materials commonly used and bought by the same people who purchase asbestos protected metal. The company now has a wide variety of specialties for building purposes, many of which contain neither asbestos nor metal in their make-up. Thus, the descriptive name, 'Asbestos Protected Metal Co.', which originally served a useful purpose became restrictive to the point of being misleading; hence the change.

SECTIONAL VIEW OF UNIT FILTER

operation while the first is being cleaned. Any kind of filtering material can be used in the cylinder, such as white waste, sponges, excelsior, or raw wool. Each cylinder is wrapped with a filtering cloth and contains a quantity of bone-black. Animal bone-black is used in all oil refineries to purify lubricating oil, and we therefore believe it to be a suitable filtering medium. This material can be washed out with hot water or gasoline and used over and over again, so that there is practically no expense for filtering.

The Burt filter is particularly desirable for use with gas or gasoline engines of large capacity, as the hot water from the engine cylinders can be used for the purpose of heating the oil. Where gas engines of large size are used, the 'unit filter' can be employed with excellent results, as the filter is furnished with special connections so that the hot water from the gas engine cylinder can be circulated in the upper part of the filter.

Each unit is so constructed that it can be used in connection with, or independent of, an oiling system, so that in case additional machinery is added to a power-plant at any time and increased filtering capacity becomes necessary, any number of units can be added, and can either be operated together as one filter or separately, as desired, without

EDITORIAL

ON May 13 the Ninth Circuit Court of Appeals, in San Francisco, delivered its opinion in the case of *Minerals Separation v. Butte & Superior*. The judgment of the Montana case is reversed, in favor of the Butte & Superior Mining Company. We look forward now to a re-consideration of the issue by the Supreme Court of the United States. As soon as the text of this decision is available, we shall give it to our readers.

ANOTHER estimate of the world's production of gold in 1917 is forthcoming. The London 'Statist' makes the total £87,983,120, equivalent, at \$1.85, to \$426,718,132. This compares with our estimate, appearing in the issue of May 4, of \$414,169,744 and with that given by Mr. Hennen Jennings, last week, of \$430,000,000. The 'Statist' quotes the United States Mint figures for Mexico, namely, £2,500,000, which compare with our guess of \$10,000,000. In the absence of statistical data we believe it correct to infer that the production was considerably less in 1917 than it was in 1916. The Russian output is given as £4,000,000, which is practically identical with our estimate of \$20,000,000. 'Other countries' are credited by the 'Statist' with \$40,000,000, whereas our estimate was \$28,000,000. If the principal gold-producing countries for which statistics are available show a decrease ranging from 3% to 17%, it is extremely unlikely that the 'other countries' continued to produce in 1917 at the same rate as in 1916, but that is what the 'Statist' assumes.

DISAPPOINTMENT is expressed by the 'Financial Times,' in London, at the report of a select committee appointed by the South African Parliament to consider means for aiding the low-grade mines of the Rand now "in a parlous position" owing to the increased cost of operation. A contrast is suggested between the "cold sympathy" shown to gold mining as compared with the "generous treatment" accorded to the farming industry in South Africa. Similar comment can be made in the United States, and the reason for the disappointment is the same here as there, namely, that mining is regarded as a speculative business, a gamble that needs no aid from the State because it brings its own, often excessive, reward; moreover, it is connected with shady dealings on the Stock Exchange, whereas the farmer is a simple man of Sunday-school character, exposed to the vagaries of the climate and the vicissitudes of markets;

he is a noble citizen worthy of a pat on the back, whereas the resourceful gold miner can look after himself rather better than most people. In short, the public is misled by false sentiment, and its attitude is reflected by those in authority, whether at Pretoria, London, or Washington.

COST PLUS has received a well-aimed blow from Mr. Charles M. Schwab. Having been called from the direction of successful shipbuilding for profit to the direction of shipbuilding for the people, on the assumption that he knows how to get ships built swiftly and economically, one of his first acts is to strike at the neat scheme evolved early in the War for limiting profits to contractors by means that fail to limit. The principle of a fixed percentage upon an unlimited cost was equivalent to cultivating profiteers in a hot-house. Mr. Schwab has cancelled the contracts of the Submarine Boat Company, at Newark, New Jersey, which was to build 160 steel ships on that basis. Recognizing the fact that prices have increased since the original estimates were made, a new contract at a flat rate has been substituted, allowing a profit of \$50,000 per ship on a cost now forecast at \$910,000. Assuming that to be a fair outlay for vessels of 5000 tons today, it appears that Mr. Schwab has saved \$6,560,000 in this single case by discarding the 'cost plus' principle.

WE do not apologize for giving five pages to the speech by Mr. Hoover appearing in this issue. It does not deal with mining or metallurgy, it does not refer to the making of money out of mining, and therefore it may seem out of place in our columns; but we shall have grossly misunderstood the mind and temper of our readers if we are wrong in deciding unhesitatingly that, to them and to us, there are today matters more important even than the technology of mining or the business of mineral exploitation. Our main concern is to further the great Cause to which as a nation and a people we are committed, namely, to break the onslaught of scientific savagery, to defeat the designs of an unscrupulous autocracy, and to frustrate the ambitions of a military caste without the sense of honor. So we are glad to be able to give further publicity to this most interesting speech by the head of the Food Administration. Moreover, we of the mining profession are proud of the work Mr. Hoover has done in Belgium and is

doing now at home; we are keenly interested in anything he has to say about his work and we wish continually that he may be granted the good health required to direct it successfully to the very end—peace—for which we pray only on the condition that it shall mark the accomplishment of our purpose.

IT would enormously facilitate the development of mineral deposits, especially those capable of yielding some of the minor metals and refractory materials, and it would encourage many chemical industries, if classified lists of the substances controlled by the various committees at Washington were made public. As matters now stand the owners of mineral deposits, or those who discern the opportunity for some useful enterprise based upon accessible raw materials, are not able to ascertain readily the proper bureau or committee to address for the purpose of offering their supplies to the Government. As one committee-man recently wrote to us, "the same group of mineral substances may be dealt with from slightly different viewpoints by four or five of the organizations listed." Lack of co-ordination between the committees often makes it extremely difficult to find where a particular product is needed. A Joint Information Board exists, but as a directory it is confessedly deficient. The Overman Act is meant to bring order out of the confusion by a re-distribution of jurisdiction on a more rational plan, but it would seem to be relatively easy for each department, bureau, committee, and sub-committee to list the raw materials it requires, the uses to which they are to be applied, and the kind of industries simultaneously controlled by the same division, and to report these to the Information Board, where a corps of trained cataloguers could index the data in short order. Monthly indices published by the Government, and made accessible at every post-office, would materially help the people to reach the right officials with their offerings of supplies. Obstacles against such co-operation are useful to the Kaiser and must be overcome.

THE free-born American, with his insistence upon the invincibility of native talent, was an interesting product of the forceful epoch of the pioneer, but he is destined to disappear before the demand for another sort of talent, trained in the use of intellect to achieve results in accordance with the experience and understanding of the past. The Government, for example, has instituted a course of instruction in the principles of industrial management. This, we need hardly explain, has nothing to do with high finance; it pertains to the successful management of men, the application of recognized principles of labor economics, of industrial organization, management, and statistics. It is not a little singular that a nation so insistent upon a universal common-school education for its children, should have developed a widespread scorn of higher training in the great field of commercial and manufacturing enterprise. Business men have insisted on the old blundering way of the empiricist. Experience is a good teacher, but it is slow and hard, and in the end it is narrow. The knowledge accumulated by our predecessors, sifted, collated, and set in order,

becomes science, and this can be taught. A student equipped with that science is prepared to adjust himself to the correct course of human activity in any sphere more readily and usefully than one lacking such mental discipline. Mr. Henry P. Kendall, the chairman of the Committee on Industrial Relations, quotes an official of the Industrial Service section of the Ordnance Department as having said recently that "no labor difficulty has been brought to the attention of the Department that could not have been foreseen and avoided if the factory in question had already established a modern employment department." The course now initiated by the Government, because of its discovery that the average manager trained in the old school of empiricism is lacking in competency, started at the University of Rochester, in New York, last March, when 20 prospective employment managers were sent, by manufacturers having war-contracts, for a six-weeks intensive training in the theory and practice of these functions. The work is endorsed by the Educational Committee of the General Staff of the War Department and the War Industries Board. The need for special training was discovered when it became necessary for men to deliver under stress what the best disciplined brain should do under normal conditions, and the average efficiency proved to be low. It is another of the signs of that awakened and proficient type of American whose influence will be supreme in the more disciplined days after the War.

Taxation and Risk

The readers of this paper will share our pleasure in publishing a letter from Mr. H. Foster Bain, now coadjutor to the Director of the U. S. Bureau of Mines, especially when he writes on a subject of such timely interest as the incidence of the excess-profit tax on mining enterprise. It will be noted that Mr. Bain anticipates an amendment of the law bringing it more in harmony with the conditions governing the actual profit earned in mining. Apparently it has needed an excessive taxation to bring home a recognition of the fact that a mine is a wasting asset and that dividends are not 'income' until the capital expended on the mine has been redeemed. If promoters and directors choose to talk of mines as 'investments,' to regard dividends as 'income,' and to allow share-gamblers to place what is often a misleading valuation on mining property, it is no wonder that the tax-collector, anxious for revenue, has taken them at their word. At the same time it must be allowed that there is a considerable portion of the public that has become thoroughly sophisticated in these matters, so that the share-valuation of some of our big copper mines is close to the present value as determined by experts. The discussion of mining finance precipitated by the proper inquisition and the legitimate taxation—for war purposes—of mines by the representatives of the Government should do great good in educating the public, if, as we insist, make-believe of any kind is detrimental to a civilized community. The wording of the Act imposing the excess-profit tax is vague, if

not contradictory. Apparently it is assumed that a man can look at a mine and determine its value as readily as a real-estate dealer can appraise a city building. Moreover, the law indicates that valuation should disregard profit, keeping an eye only on the assets. Some mine-operators, who have done their best to comply with the requirements, have taken the ore tonnage, gross value, the price of the metal produced, and the cost, therefrom deducting the profit. Taking the estimated life of the mine, they have used Inwood's tables to arrive at the present value of the property. The law says that the 'en bloc' value of the ore as on March 1, 1913, is to be the basis of taxation, and from it the value of plant is to be subtracted, in order to arrive at the value of the ore. It is even practicable to apply the figures of ore extracted backward since March 1, 1913, and therefrom arrive at the 'en bloc' value at that date. Mr. Bain asks "What is the risk-rate in mining?" He desires to start a useful discussion on the subject. We invite our friends to come forward and express their views, so that the ideas of the profession may be unified and then submitted to the authorities at Washington. By a fortunate coincidence we are enabled to publish a thoughtful article on the valuation of mines by Mr. W. W. Whitton, who analyzes the formula brought forward many years ago by H. D. Hoskold, one of the first writers on the subject to recognize the necessity for setting aside a part of the dividend from a mine to provide a sinking-fund that will return the capital when, at last, the mine is exhausted; in short, that the capital put into a mine is a loan, to be repaid with interest. If this view be accepted, it is wrong, says Mr. Whitton, to require a mine to pay during its entire life a high rate of interest on the whole amount originally used. As a matter of fact, those financially interested in mines are not 'investors,' with rare exceptions, but 'speculators'; that is, they buy not to hold until the mine is exhausted, but to sell when the share-quotation affords a satisfactory profit or when they obtain information that the end of the mine is in sight. To such speculators the raising of the dividend-rate is an index of the probable market for the shares and not an increase of income from an investment. The main difficulty of taxation, therefore, is the fact that the proprietary, that is, the shareholders in a company, represents a fluctuating entity, changing from year to year. The shareholders that subscribed to the working capital may have sold out before the mine began to pay dividends, and the shareholder that was in the company during the prosperous years of the mine may have liquidated his holding before the arrival of the lean period that precedes exhaustion. A large risk is inherent, because mining is hazardous, particularly the exploitation of small masses of high-grade ore, such as those of gold and silver. The persistence of an orebody is always doubtful except as far as it is actually proved by mine-workings or bore-holes, but the continued persistence of ore is commonly assumed in the share-valuation of a mine, and usually with an optimism not justifiable by experience. It is a brutal fact that more money has been lost by the public—to insiders—by speculation,

or 'investment' as it is usually called, in the richest and biggest mines than was lost in a score of wild or fraudulent ventures that proved miserable failures, as mines, whatever success they may have had as counters for a gamble. There are two risks to be faced, the first is the proportion of net profit to be won from ore that is 'proved,' and the second is the probability of finding more ore. The attractiveness of mining depends usually on the second factor; when mining rarely does come down to a safe 'investment,' it is then no more attractive, to the intelligent speculator, than municipal bonds, preferred industrial stocks, or any other form of gilt-edged security. Formulas for expressing the probabilities of ore-extension in depth have been submitted to the mining profession from time to time, but they excite no special interest, because the experienced engineer knows that they are unreliable. No formula can cover the unlimited variability of the principal factor in the problem, namely, the eccentricity of ore deposition. Consider a small, but rich, gold mine, at Cripple Creek, for example, that is paying 25% on its share-capital, with the assurance of not more than one year's life. As a rule the richer the mine the smaller its proportion of ore in reserve. Then consider a mountainous mass of low-grade copper ore, such as that at Bingham, assuring operations for 30 years, provided the price of copper remains at a given figure. Allowing for the smaller fluctuation between the values of gold and of copper, as expressed by the index-price of staples, there is still a manifest difference in the risk inherent in the gold-mining venture as against the copper-mining enterprise. A risk-rate of 50% might not be too large for the one and 10% might not be too small for the other. These are some of the considerations pertinent to the question submitted by Mr. Bain; we hope to elicit a useful discussion on the subject.

Price-Fixing of the Minor Minerals

Mr. Pope Yeatman, head of the Non-Ferrous Metals Section of the War Industries Board, is not satisfied with the War Minerals Bill as it left the House. He appeared before the Committee on Mines of the Senate and insisted that the power to fix prices be re-instated. This conforms to the view we have presented. The authority of the War Industries Board over the matter was explained in these columns last week. It gives, not a power to fix, but the privilege of reaching an agreement with producers, after a roundabout tedious process of investigation and recommendation from bureau to bureau, ending in a price that will last only until changed by a new arrangement. It lacks the value of finality; for men of small means cannot risk their all in a mine when they cannot depend upon the market. The gentlemen of the House of Representatives seem not to understand the peculiarities of the deposits of many minerals specified in this bill. They may derive their ideas from the mining law, which is based on the conception of tabular veins, like the ham in a sandwich. If orebodies were only tabular in form and uniform in metal content there

would be no need for this bill. The truth is they are not even veins, as a rule; they are erratic irregular masses, variable in size and richness. The dead-work is usually enormous in proportion to the ore developed; a pocket or patch of wolframite may, and may not, pay for the work to be done through barren ground to reach another pocket; chrome is segregated from basic rocks into isolated patches from the size of an egg to that of a freight-car, but usually a mass that yields a few hundred tons is regarded as satisfactory. Under such conditions the development of large tonnages is next to impossible. The occurrence of manganese is not so irregular as that of tungsten or of chrome, yet large and continuous ore-bodies of merchantable-grade are uncommon. The cost of production of most of these minor minerals is far higher than of those that can be systematically developed and mined on a large scale. The risk is proportionately greater. Either the Government must finance such mines or must guarantee a reasonable price for a definite period, otherwise no adequate increase of output is to be expected. This is a war-emergency measure, and unless it carry the power to ensure a market the desired stimulation will not be experienced; it is not enough to provide for making contracts unless the authority to contract can be delegated to local officials, because the majority of those whom this bill is meant to energize into producers cannot afford to go to Washington for negotiation nor to employ the professional talent necessary to prove that they possess anything worthy of consideration. If the Government were to contract with every applicant on the strength of his unsubstantiated assertions a new crop of grafters would be hatched to fatten on the sale of stock in bogus undertakings. The power to fix the price for a definite period, and to accept all the material offered within that period, is worth infinitely more than the authority to contract. The financing of such mines will be done by the public readily enough under these assurances. Mr. Everett Sanders, of Indiana, and other Representatives, argued that such provision might so stimulate production as to embarrass the Government with large stocks that it could not use. Mr. Courtney W. Hamlin of Missouri suggested that the output would go mainly to those engaged in manufacturing war-supplies, which is true. The guarantee applying to materials needed under the present exceptional conditions is the thing that is urgent; it is the prospect of loss in the event of an early cessation of this extraordinary demand that is to be averted. To do this might throw a responsibility upon the Government to purchase a few million dollars worth of minerals at a higher price than it could realize afterward in the market. What is the risk of such a loss to the nation as a whole, compared with the probability of being retarded in the production of munitions for effective warfare against the barbarians? The debate in the House developed the conviction that a number of large mining concerns were already able to produce manganese and other minerals in considerable quantity, and that no further powers were required, because the means of financing through the War Finance Corporation in conjunction with the

power to contract exists already. In this we detect the opportunity for profiteering. Many small miners would be prevented from making their contribution to the total output; the supply would be inadequate; and the large producers could then obtain higher prices than would be necessary if the Bill in a broadly equitable manner, without discrimination or favoritism, opened the door to poor and rich alike.

Postal Exchange With Mexico

Many of our readers will be pleased to learn that the resumption of exchange by international money-order with Mexico has been authorized by our Government. Such relations have been suspended since October 1909. While the revolution was at the boiling-point every semblance of orderly government was dissolved; and to cash money-orders would have been like flinging good money into the sea. Since the recognition of Carranza's government, however, our failure to remove the restrictions upon this kind of exchange has been much more than a commercial disadvantage; it has served to restrain the development of cordial personal relations between Americans and Mexicans. There is a value to commerce beyond the mere financial gain involved in it. Men grow to like those with whom they have pleasant trade relations; a Mexican who orders a watch or a pair of shoes from an American advertiser, and is pleased with the article that is sent to him, feels more kindly to all Americans. He who orders a book from Mexico learns something of the warmth of that southern blood that is had mainly when incited to evil by malicious leaders. It is the many small business transactions, which have the effect of encouraging genial relations between man and man, that the postal exchange chiefly stimulates; it has a profounder influence on the people than larger operations liquidated through the banks. The movement of sisal and of lead ore to the United States, and of corn and sugar to Mexico, negotiated by effecting trade balances in the clearing-houses, fails to engender the sentimental feelings that are at the bottom of international goodwill. Whatever tends to strengthen the ties between ourselves and our neighbors should be sedulously cultivated. In this connection it may be noted that easy exchange in small articles between the United States and Spain has been rendered impossible ever since the Spanish-American War because the facilities for exchange through the Post-Office have been suspended. It is time that this barrier were removed, and we believe that the diplomacy of Ambassador Willard could accomplish it. If an American wishes to subscribe to 'Blanco y Negro,' or to purchase a clever Barcelonan knitting-machine for domestic use, how will he send the necessary driblet? He must go to his bank and buy a draft on London or Paris. When the book is worth only 90 cents the case becomes ridiculous. The result is that the money is not sent, and one more American is cut off from helping his country through getting a little closer to a Spaniard and thereby awakening a cordial interest each in the other.

DISCUSSION

Excess Profit and Mine Taxation

The Editor:

Sir—In your editorial of April 27 on the War Minerals Bill, you bring up a point of first importance; one touching on the necessities of war taxes on mines. An amendment has been submitted to the bill now before Congress which if adopted will relieve the new properties called into being to meet this emergency from the excess-profit tax. This, it will be recognized, is a matter of first importance since many of the particular properties in view will be short-lived and it would be impossible to get them opened up if the usual construction of the tax law is to be applied to them.

It is probable that a serious attempt will be made to amend the general income and excess-profit tax law by this Congress. In that connection there are two points on which it would be helpful to have discussion with mining men. The first is the depletion charge to cover exhaustion of ore-reserves. For my own part, I anticipate no serious difficulty here, since the existing law recognized the fact that depletion may be charged, provided that it is not larger in any one year than the gross output. This is as much as mining men have a right to expect. The difficulties here will be in the fact that money spent on development often results in the bringing into the reserve of orebodies of a principal value largely in excess of the development charge. If this was not so mining would not be profitable. With better companies this excess value is promptly shown in the share-value, but under the existing law and interpretation, it would not be taken into account in taxes. In other words, depletion charge could only run against the amount charged for development. The net result of this is to value a mine differently for taxation purposes than for market purposes, and so the investor may actually pay for his shares more than he can ever get back from depletion. There is probably no injustice here, but it is a point which should be appreciated and taken into account when anyone buys shares.

The second point is: what is the risk-rate in mining? If it be assumed that a tax law be so drawn as to cover satisfactorily the principle of wasting assets as applied to mines, this still only takes care of the successful property. In mining and in oil-production, it is necessary to spend money on a large number of prospects in order that one may be found that by its success will cover the losses on the others. Some way the profits in the industry must be large enough to cover this charge or production will cease. This is a legitimate risk and should be taken into

account in fixing the return which will be allowed to mining companies before the profit-tax is applied. So far as I am aware there is no consensus of opinion as to what this risk-rate is. It would be very helpful to have expressions of opinion from engineers, and particularly any tabulations as to what the actual cost in money has been which has gone into properties of average success. In getting out these figures it should be remembered that other industries have risk-rates and that this is not a problem peculiar to mining. At times we deceive ourselves by thinking that a manufacturer or a merchant has always an established and growing business and that the risk element has disappeared so far as he is concerned. A little study will show that this is wrong. The rate in the business may be different from that in mining, but it is there, and the helpful thing will be to find out what the real risk-rate applied to various industries is so that it may be used in determining the incidence of taxation. If you will take the lead in stimulating a discussion along these lines, your action will, I am sure, be appreciated by Washington authorities.

H. FOSTER BAIN.

Washington, May 4.

Flotation of Semi-Oxidized Silver Ore

The Editor:

Sir—E. J. Attekison's article on this subject in your issue of April 27 gives to the public some interesting data concerning the use of gasoline as a reagent in flotation, and, as Mr. Attekison calls it, "a substitute for acid." He states also that while the function of the gasoline is doubtful, the idea is that it cleans the oxidized mineral and allows the sodium sulphide to act upon it. Does he mean that it removes the oxide film? Several times I have resorted to the use of gasoline as an additional reagent, but I am inclined to believe that its function is to remove films of foreign oils and greases only.

I am very sorry that Mr. Attekison did not preface this article with a description of the ore. I believe that most writers have not given enough attention to this factor. In all of my work, I have found that the mineralogical composition of the ore, and particularly that of the gangue, is the factor governing the use of reagents, and to a greater extent, the use of various oils.

Acid is not always necessary in floating semi-oxidized ores. Various experiments I have made have proved this. Often, by the addition of acid, the grade of concentrate will be improved, but the amount of valuable

mineral (gold, silver, galena, or whatever is sought) will be the same in both cases.

A short time ago, in an attempt to repeat some work on a galena-limestone ore, my first attempts were failures. Upon examining the container (I was using a ready-mixed pulp) I discovered that some oil from an overhanging shaft had dripped into it. The addition of 0.1 cc. of gasoline to 2000 cc. of slime immediately remedied the condition. In this particular ore, acid had always proved detrimental, and the gasoline therefore was not a substitute.

On another ore, for which acid is decidedly necessary to hold back finely divided sericite, the substituting of gasoline for acid was a complete failure. The froth carried only a trace of the value. Additional sodium sulphide (the ore was partly oxidized) seemed to improve conditions slightly, but the best recovery I could make was only 40%, where a 90% recovery was possible with acid.

L. B. PRINGLE.

Bonne Terre, Missouri, April 29.

[Mr. Pringle makes a good point when he insists that every article on metallurgical results should include a detailed description of the ore.—EDITOR.]

Nitrate Lands in Chile

The Editor:

Sir—Your New York correspondent of March 23, 1918, announces the advertisement in the New York papers of a sale by auction, on August 10 next, of 9,906,402.886 metric quintals of 'nitrate land' in Chile, and comments upon the fact that the sale of about a billion tons of 'caliche' suggests some more ambitious scheme for the treatment of the material, etc.

Nine billion quintals at an average of 23 centavos (at 18d. per peso) each, as stated by him, make a total of \$820,000,000 U. S. currency, so that if we average the 14 lots into that amount, the average price per lot would be over \$58,000,000; and as auctions for nitrate lands in Chile are conducted as are other open auctions, except for the rule that a certificate of deposit of 10% of the minimum purchase price must be presented by each bidder before entering the auction, one can picture this auction as on a truly regal scale, each bidder having made his deposit of about \$6,000,000 in cash and the bids advancing five to ten million dollars at each raise.

Anyone familiar with the nitrate industry, however, knows that the Government has explored no such extent of nitrate lands; moreover, that it is the policy of the Chilean government to sell the lands in relatively small lots to encourage competitive bidding.

It happens that most of the lands for sale are lands which were carried over from the auction of September last, when nobody made a sufficiently high bid to buy them. A perusal of the Government estimates and sampling-lists published at that time, shows that in the advertisement now published, seven out of the fourteen lots have a decimal point changed to a comma followed by a zero. For instance, the San Juan de Soledad lot,

which in the estimates prepared by the Chilean government is given as containing 2,546,826.26 quintals, has become in the advertisement in the New York papers, 2,546,826,026 quintals, or 1000 times greater. The same error occurs in six other lots.

The metric quintals advertised refer to nitrate content and not to caliche as supposed by your correspondent. Moreover, they are the net nitrate yield of the ground as estimated by the Chilean government engineers.

The statement that "Payment is to be made at a standard rate of exchange of 18 pence (36 cents) per peso," made by your correspondent is also wrong. Such sales are always in Chilean gold pesos, which at par are worth 18 pence sterling. Recently they have been quoted at somewhere about 21 pence (42 cents) per peso.

HUNTINGTON ADAMS.

New York, April 29.

[This is a good example of the errors arising from the unnecessary use of the decimal point. To say that the land contains 2,546,826.26 quintals is a specimen of the meticulous precision that really says nothing more than 2,546,800, but invites either misunderstanding of the method of estimation or leads to typographical blunders of a gratuitous kind.—EDITOR.]

Solubility of Wolfram

The Editor:

Sir—In your issue of December 8, 1917, there is a reference to the solubility of wolfram. I recently discovered in India a wolfram-scheelite deposit where there was apparently a most rapid decay of the wolfram, pieces of bright wolfram forming the kernel of masses of gossan or friable lumps of iron oxide. There was absolutely no trace of detrital wolfram in the neighborhood of the lodes. The deposit was in quartzite and associated with apatite and molybdenite.

PHILIP E. BILLINGHURST.

Calcutta, March 5.

GRAPHITE PRODUCTION of the island of Madagascar, East Africa, in 1917 was 35,000 tons, a gain of 4500 tons. Stocks there at present amount to 15,000 tons. The U. S. Consul at Tananarivo states that there has been recently a considerable slump in the prices of graphite on the local market. First-quality material, averaging 90% carbon, which a few months ago brought 750 francs (\$144.75) per ton, brought only about 500 francs (\$96.50) toward the end of February 1918. On the other hand, because of the general situation of the graphite market, few offers are being made locally for the purchase of this mineral.

TIN recovered by dredging in Siam during 1917 amounted to 6,306,000 pounds. There were 16 boats operated, against one in 1908, digging 10,000,000 cu. yd. of tin-bearing ground. The yield last year was from 0.60 to 1.16 lb. per yard. The black tin (SnO_2) is reduced to metal at Singapore, and enters the trade as Straits tin.

ARRANGEMENT OF SETTLERS AND SLAG-CAR AT LEAD BLAST-FURNACE

Smelting Methods at El Paso—I

By COURTENAY DE KALB

Smelting practice never long remains stationary. Changes in the character of the ores available, new methods of concentration, and the urgency of the market-demand, introduce new problems and these must be met by modifications of previous methods. At the plant of the Consolidated Kansas City Smelting & Refining Co., at El Paso, important developments since the interesting paper by H. F. Easter, in the *Trans. A. I. M. E.* in 1915, give pertinence to a new discussion. This plant for many years treated a great preponderance of lead ores. It depended fundamentally upon deliveries from Mexico. The revolutions in that country shut off the supply altogether for a time, and the interference both with mining and with shipment is still serious. At present the total receipts of Mexican ore average about 150 tons per diem, most of which is from the Potosi Mining Co., operating in the Santa Eulalia district, Chihuahua. Meanwhile the war-demand for lead encouraged smaller shippers throughout New Mexico and Arizona, and the diversified offerings have exaggerated the heterogeneous composition of the ores from which the mixtures are made. The El Paso smelter, moreover, treats the total output of flotation concentrate and ores from Chino, and thus a distinctive character of the plant, as one in which lead and

copper metallurgy overlap, is still maintained. One of these days a brand new plant will be built, but until then the staff confronts the interesting and difficult problem of meeting the demands of economy in competition with newer plants by careful management and by modification and improvements of the old equipment. The El Paso plant is a meeting place of appliances representing a long epoch of metallurgical history, and at the same time it is a leader in the march of progress. This is a record that reflects high credit upon the staff in charge. Starting with a Godfrey roasting-furnace that dates back over 20 years, and ending with the adaptation by Philip S. Morse of the hooded lead blast-furnace, it will be seen that the El Paso works present features of no common interest.

The Godfrey apparatus is of the turret type, recalling the methods of a generation ago when the mechanical roasters were in process of evolution toward the perfected models of the Wedge, McDougall, and Herreshoff of the present day. Unlike the Pearce turret, which introduced the circular hearth with revolving arms, the hearth itself revolves, while the plows are stationary, being wrought-iron strips bolted to a heavy casting, which is built into the roof, uncooled except for a slight

air-leakage. It has a single hearth, 26 ft. in diameter, supported upon six wheels near the periphery. In spite of the great weight to be moved, it requires only five horsepower, and it desulphurizes 30 tons in 24 hours. The three Godfreys in the plant are driven from a single line-shaft. The rate of travel is one revolution in two minutes. Each furnace is fired at two points, the fuel being chiefly crude oil from which a portion of the volatile compounds has been distilled. The average consumption of oil is about 400 to 500 bbl. per month for the three roasters. The charge consists of highly sulphurous leady material, and may be a mixture of ores, concentrates, and matte, especially such as contains considerable iron sulphide. The object of treatment in these machines is merely that of pre-roasting in preparation for subsequent roasting and sintering in the Huntington & Heberlein pots; hence the average work is done to reduce a sulphur content of about 18% to a residue or calcine containing 12%.

There are eight of the H. & H. pot-roasters in the plant, set at an elevation of 8 ft. above the ground in a steel-framed structure. The cast-iron pots are eight feet in diameter at the top, drawn in at the grate to a diameter of six feet. The grates are castings $\frac{1}{2}$ in. thick, made in segments. Holes $\frac{1}{4}$ in. diameter and $1\frac{1}{2}$ in. apart are cast in the segments. Over each pot is a stationary circular hood, and the hoods connect with a down-take flue. It should be stated that one of the Godfreys has a fire-box for burning ordinary run-of-mine bituminous coal. This

condition results without special prevision, since the materials as offered in the routine business of the smelter contain such a desirable excess of iron. It should be noted, however, that experience here and at other plants has shown that in roasting lead ores it is essential to have considerable silica present to reduce the loss of lead in roasting. Equal proportions of lead and silica would not be amiss. It has been held generally that the function of the silica was to form a silicate of lead, thus preventing the lead from being reduced too easily and thereby limiting the loss by volatilization; but another item has to be considered, namely, that in roasting lead with iron, mainly in the form of sulphide, the proportion of sulphur might readily become so great, if no silica were present, that the temperature in roasting would rise too high, in consequence of which the presence of the larger amount of sulphur might exert some reducing action, involving lead losses that would not take place if the excess of iron and its accompanying sulphur were diluted by adding inert silica. Therefore the silica, by reason of its inert character, may perform a useful office in helping to reduce the loss of lead by volatilization. Moisture is added to the extent of 10 to 12%, this being essential to the process of sintering; without it the mass remains granular and will not agglomerate. The function of the water is not definitely explained, but it would appear that it serves, first, to confine the zone of the silicate-forming reaction to a horizontal layer that advances up-

OUTLINE OF DRAFT-HOOD FOR LEAD-FURNACE

is maintained with special reference to the operation of the H. & H. pot-roasters. When ready to charge a pot some of the coal from the Godfrey is brought alight and dropped upon the grate, covering it to a depth of two inches. Upon this is fed calcine, also from the Godfreys, dampened and mixed with fine material that needed no preliminary roasting. A charge consists of 11,000 lb. The average sulphur in the material fed to the pots is 12%, and there is a considerable excess of iron over the silica present. This serves to protect the lead against forming a silicate, and it happens that this advantageous

ward through the mass, reaching a temperature of about 1100°C. at which the iron will combine with the silica, and, second, to absorb heat just above this zone by vaporizing the water, thus preventing an increase of temperature that would result in fusion. If unrestrained in this manner, the charge, being shallow, would be subject to the conditions of heap-roasting, the heated gases would escape through channels, a small amount would be slagged and matted, and the remainder would tend to disintegrate. As the operation is conducted the product becomes a porous well-agglomerated mass, containing 3

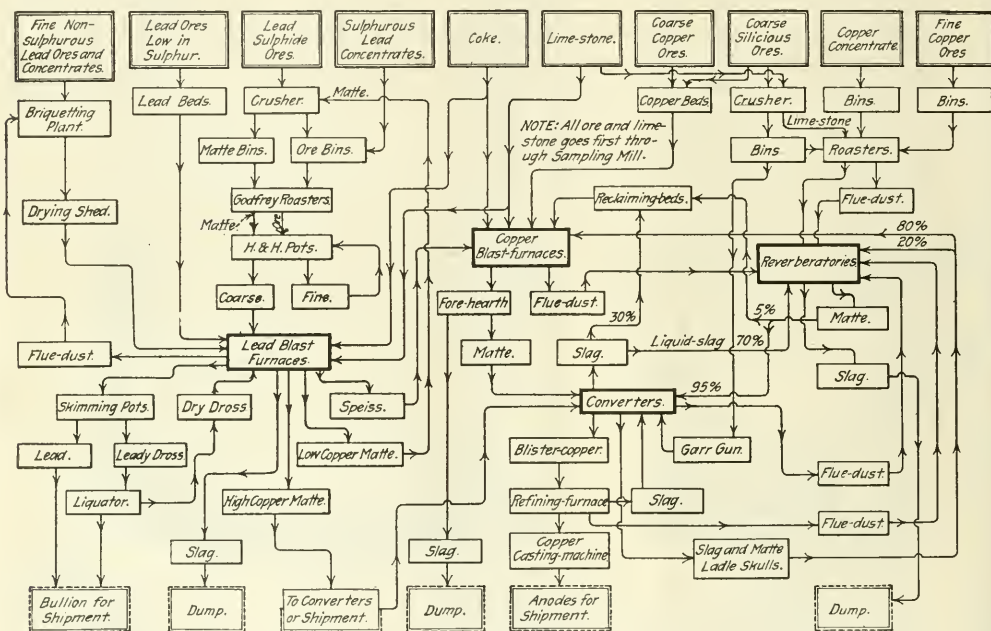

to 6% of sulphur. The analysis of the material, after combined Godfrey and pot-roasting, varies greatly from day to day, but the following examples are representative:

Analyses of Roasted Lead Ores, El Paso Smelter

	A	B	C	D
	%	%	%	%
Lead	11.8	20.6	30.0	8.5
Copper	3.0	5.0	1.8	15.0
Silica (SiO ₂)	33.8	12.0	13.6	9.0
Iron oxide (FeO)	19.1	27.6	24.3	43.0
Manganese oxide (MnO)	1.0	0.6	0.7	0.5
Lime (CaO)	2.9	2.4	1.5	2.1
Zinc	8.8	6.5	6.5	2.5
Sulphur	3.8	6.3	6.2	4.0

a side, $3\frac{1}{2}$ in. diam., delivering blast under a pressure of $3\frac{1}{2}$ to $5\frac{1}{2}$ in. mercury-gauge. The hearth-area at the tuyere-level is 46 by 162 inches. The furnace-base is of brick, 7 ft. 2 in. by 15 ft. 5 in. inside the crucible-plates. The latter are 3 ft. $4\frac{1}{2}$ in. high, supported on a steel pan. The crucible is 2 ft. wide at the bottom, and 3 ft. 6 in. at the top; 12 ft. 9 in. long, and 2 ft. 6 in. deep. The leadwell is 12 in. square, but the Arendt-tap is apt to freeze up because of the large amount of copper in the bullion. Accordingly the separation of the products of smelting is effected almost wholly in large fore-hearths or settlers. These are somewhat unusual in being made of cast-iron about $1\frac{1}{2}$ in. thick, and in being unlined. The settler nearest the furnace has about six inches of slag poured

FLOW-SHEET OF EL PASO SMELTER, CONSOLIDATED KANSAS CITY SMELTING & REFINING COMPANY

The crushed matte is roasted in the Godfreys, sintered in the H. & H. pots, and then charged in a blast-furnace devoted solely to concentrating matte.

The oxygen taken up in roasting roughly balances the sulphur eliminated, so that the weight and relative proportions of the constituents are not altered. The charge is dropped from the pots to a floor 8 ft. beneath, which breaks most of it to the proper size for the blast-furnace. The larger chunks are broken with sledge hammers; automatic appliances for handling and preparing the ore and other materials not being used to any extent.

Six blast-furnaces constitute the full lead-smelting equipment, but usually no more than five are in operation. These are 32 ft. high, smelting a charge-column of 19 ft. The lower water-jackets are 4 ft. high and the upper are 2 ft. Each furnace has 16 tuyeres, that is, 8 to

into it before being put in service; this is to protect the bottom plate from the matte; a few bricks are also placed behind the matte-tap plate; otherwise the settlers are without lining. Their size, moreover, is not large, namely, 8 ft. 2 in. by 4 ft. in horizontal section, and $4\frac{1}{2}$ ft. deep. Each settler is mounted on wheels, so as to be easily removable when repairs are needed, and it is provided with two tap-holes at different levels for drawing off the lead bullion and the leady copper matte, respectively. The slag, still containing some entrained metal, overflows into a second settler, the function of which is to afford a quiet pool of slag where the remaining matte may settle. When the settler freezes, so that this pool has become reduced to a small size, a new one is put in its place, the old settler being taken to the rip track, where the sides and ends are removed, and the

frozen slag dumped as a solid mass. This is broken and returned to the furnaces as foul slag. Nothing is ever tapped from the second settler: the slag merely passes into and overflows from it. If zinc is present in great abundance it may chill in 24 hours. The slag assays

STACK FOR COPPER-FURNACE FUME AT EL PASO SMELTER

about 1% sulphur, 0.20 to 0.45% copper, and 1 to 1½% lead.

A comparison of a typical slag-analysis with the flue-dust representing recovery from gases issuing from the lead blast-furnaces will be interesting:

	Flue-dust		Slag
	%	%	%
Lead	17.4	14.8	0.90 to 1.50
Copper	2.0	1.5	0.20 to 0.45
Silica	17.0	18.3	32.50
Iron (FeO)	30.0	26.0	32.80
Manganese (MnO)	1.0	1.3	2.00
Lime (CaO)	7.0	6.5	22.00
Alumina (Al ₂ O ₃)	3.80
Zinc	3.1	3.2	4.00
Sulphur	2.3	2.9	1.00
Arsenic	1.0	1.0	0.35
Silver, ounces	14.8	20.0	0.50

The matte drawn from the first settler contains approxi-

mately 10 to 25% of copper, 14% of lead, and 21% of sulphur. The proportion of copper varies with the ores received, and for the sake of the crucible it is desirable to keep it low. This matte is cooled, crushed, and returned to the Godfrey roaster, thus remaining in the lead-smelting cycle. The slaggy matte from the second forehearth, however, is of variable composition, sometimes containing much lead, in which case it is returned to the lead-cycle, but when it is low enough in that metal so that the recoverable fraction would cost more than its market value it is sent to the copper converters, where the copper goes into blister and the lead is volatilized. The grade of matte from the lead department that is either shipped or sent to the converters is what comes from a furnace smelting roasted matte exclusively, and it is the only matte produced by that furnace. This matte is caught in and tapped from the first settler, the same as if the furnace were working on ore. If high enough in copper and low enough in lead it is treated in the converters, the lead in that case being volatilized, but if the lead content is too high it is shipped to some other

SLAG DISPOSAL AT LEAD BLAST-FURNACE

plant prepared to save the lead. The lead-furnace that is concentrating matte, which may be any one of the battery of furnaces, produces a 40% copper-matte.

The lead-furnaces each smelt on an average 145 tons per day, and to this is added about 15 to 18 tons of coke,

which is fed in separate layers between the successive charges of 7400 lb. each of the bedded ore-mixture. The average 'mix' carries 10% lead and $1\frac{1}{2}\%$ sulphur. The feeding is done by bottom-dump cars running on a 5-ft. track, and operated by an electric motor. The charge is dumped directly over the top of the furnace, which is entirely exposed and unprotected and at the same time absolutely fumeless. Here is one of the most interesting improvements in the plant. Copper smelters will recall an attempt to achieve the same result many years ago in Europe. This was by means of a series of tubes, sometimes made of cast-iron, sometimes of cast blue-metal or blister-copper, placed in a row along the central horizontal axis of the furnace and extending to a depth of several feet below the upper level of the charge. It gained no currency in American practice, where the tendency was toward fast driving, which meant running with a hot top. Nevertheless, it was impossible not to be impressed with an inherent merit in the device. I was deeply interested in seeing it as applied to the peculiar conditions of copper smelting in the works of the Cie. du Boleo, at Santa Rosalia, Baja California. The ore there smelted was a mixture of copper carbonates, silicates, and oxides, in a highly argillaceous gangue, which tenaciously retained large amounts of moisture, balling up so as to make masses that would not pass through a 3-in. grizzly. Part of the ore was compressed into briquettes about 3 in. diam., in order to put it into practicable shape for smelting. Through such a mass of damp charge it is evident that only a high blast-pressure and a great excess of coke would have prevented the prompt freezing of the smelting-column without the use of some such device. This apparently solved the problem in a satisfactory manner. The smelter-fume passed through the tubes to the downtake flue, the charge settled evenly, and no gases escaped except a little steam driven off as the heat from below vaporized the moisture. It was thus possible to smelt under favorable conditions of blast-pressure and fuel consumption. The basic principle of this plan, highly improved, and introducing new and advantageous features, has again emerged at El Paso in an adaptation from Australian methods, under the direction of Philip S. Morse, the able consulting metallurgist of the lead department. The method had long been used in central European lead plants before it was applied in Australia. At El Paso it is called a hood. The accompanying illustrations show the elements of the appliance. It consists of a box, closed at the top and at one end, but open to the down-take flue at the other end, and also open below. In transverse section it is roughly thimble-shaped. Cast-iron plates of suitable form, built into the brick shaft of the furnace, support it so that the lower narrow end is 6 ft. $6\frac{1}{2}$ in. below the top. The hood is tapered toward the bottom to correspond with the batter of the shaft-wall, maintaining a space 2 ft. wide on each side lengthwise the furnace. The charge-car is seen centred over the plate covering the top of one wall. The door on the

left side is dropped, and, as the charge dumps, the coarser pieces gravitate toward the hood. Thus the greater part of the fine material remains on the outside next to the shaft-wall, while the coarser ore accumulates at the centre, leaving the charge more permeable by the gases directly underneath, and the fume naturally follows this line of least resistance into the hood and thence to the flue. Doors are provided in the top of the hood in order to observe the condition of the charge and to gauge the heat of the furnace. The beneficial results are numerous and important. In the first place no fume escapes from the top of the charge at any time unless the proper burden is not maintained. Inattention on the part of the workmen to charging the furnace when needed results in the escape of smoke because the column settles to the lower edge of the hood; this would soon make the charging-floor uninhabitable, and the only remedy is to feed the furnace. The concentration of the heat in the centre of the furnace tends to reduce the formation of wall-accretions, and the fine ore being kept toward the outside is not in the path of the greater movement of the gases. This has an important effect in curtailing the dust-loss. Moreover, it is found that the coke-consumption is materially less than with furnaces operated alongside, that treat identical ore-mixtures, but are unprovided with the hood.

Under the old method the volume of gas going to the flue was enormous owing to air drawn in above the charge. This dilution is entirely avoided by the use of the hood. Furthermore, under the former system, the temperature of the gases entering the downtake was 300°F. , owing to the peculiar ore-mixture smelted at the El Paso works, and no means could be found to reduce the furnace-temperatures until the hoods were installed; then the furnace-temperature fell about 100° , while the smelting-conditions were improved. The one defect that has been disclosed in practice with this appliance is a tendency of the long side-plates to warp, which then permits some fume to escape. This will be remedied by a special form of angle-bar riveted to the sides. It has given such remarkable results that it would not be surprising to see renewed attempts made to adapt the idea to copper smelting.

(To be Continued)

LEAD ore imported in February amounted to 2,361,276 lb., against 2,883,657 lb. for the same month in 1917. For the eight months ending in February the imports totaled 22,677,110 lb., against 27,788,213 lb. for the same period in the previous year. Imports of pig-lead, bars, and old lead for eight months ending in February were 16,346,262 lb., against 7,068,963 in the corresponding eight months of the previous year, and 137,218 lb. in the year before that. Exports of pig-lead, bars, and old lead for the month of February were 20,636,407 lb., and for the eight months 143,862,148 lb. For this period in 1917 the exports amounted to 141,583,242 lb., and in 1916 to 143,203,251 pounds.

Food for the War

By H. C. HOOVER

*The Food Administration is purely a war institution. Its first and primary concern is the feeding of our own people and those of the Allies, and thereby the maintenance of the strength of all men, women, and children, both there and here, and thus the strong arm of our soldiers.

The necessity for the creation of Food Administrations in all the countries at war with Germany arises solely from the situation in overseas shipping. Over one-third of the world's carrying capacity has been diverted directly and indirectly to military purposes, and of the remainder there has been an unceasing loss during the War. There is an abundance of food accessible to the seas, but there are not the ships to carry it from every point and to still conduct the War.

The first adjustment of this situation has been to isolate the more remote markets. There are today abundant stores of food in Australia, the East, and in South America. Ours and Canada's are the nearest supplies to the Allies, and better protection from submarines can be given to ships on the Atlantic lane than on other sea-roads.

Roughly, every 5000 tons of food to the Allies requires 15,000 tons of shipping from Australia, 10,000 tons from the Argentine, and 5000 tons from North America. Every steamer we can save from these long journeys means the possibility of an additional shipload of soldiers and munitions to France. If the Allies were compelled to go to these more remote markets for their whole food-supply today it would require over 2,500,000 tons more shipping than at present in use for this purpose. If North America could next year provide the whole of Allied necessities we could have 1,500,000 tons of shipping. Every ship we save is a ship built. The weight of our blow against the Germans will be limited not alone by the ships we build, but by the ships that we save. The measure of ships saved by food supplied directly from North America is, until our shipping expands, the measure of ships for our own soldiers.

If the Allies were forced to rely wholly upon the remote markets for their food, we would have no soldiers in France today. Nor will the burden grow less in the near future, for every ship we build will be needed to replace losses and to increase our army at the front. This is conservation of ships as well as of food. Therefore the whole war-food problem is simply and solely a determination of the amount of food that can be spared from North America; the marginal amount must be drawn from the more remote markets.

From this spring broad administrative issues.

*A speech delivered before the Pittsburgh Press Club, on April 18.

First: the amount of food we can send without injury to our people, and the method of securing it.

Second: the economic measures we must adopt to protect our people from the disturbance to nutrition and commerce by this drain of supplies.

In the daily toil of all these Food Administrations there have grown up new and practical issues in matters hitherto regarded as pure science. This administrative world today views production and the feeding of human beings and domestic animals in a new light. Terms strange to the lips of all but scientists three years ago are now our daily vocabulary. One must now reduce food to its physiological value. In considering the most concentrated and durable forms for overseas transport and for the maintenance of health and strength of populations, we find ourselves constantly reducing all food-material to the three main essences, that is, protein, fat, and carbohydrates. These strange terms are daily being more vividly silhouetted against this background of world tragedy. The European food-controllers anxiously take their stocks, not on the basis of furnishing the variegated menus for dinners, but in terms of these essences.

Europe today is eating to live, and to live it matters little, for instance, whether fats are drawn from creamery butter, from margarin, from lard, or from vegetal oil or cheese. What does matter to Food Administrators is how much fat can be secured and can be delivered to the needy points with the least use of ships. To carry this instance further, as showing the far-reaching character of such calculations, I may point out to you that at one time Europe produced most of her own fats. To do this it was necessary to import a large tonnage of forage for their animals. It requires three times the tonnage to transport fodder that it does the fats made from feeding animals. Therefore, the various Allied administrations have stopped the overseas shipment of feed for food-animals, and it becomes our duty to find increased exports of fats and to direct our production to this end.

Any broad consideration of these problems requires a constant re-assessment not only of our own food-resources, but of the food-resources of the Allies and of other markets from which food may be brought to the Allied world. North America is the greatest factor in the Allied food-pool and in the final analysis it might become necessary for the Allies to live practically on North American supplies. It is therefore of importance to review our possibilities in this direction.

Our ability to supply the Allied world with food lies in four directions:

First, the United States usually produces a small surplus of food for export over and above our normal

consumption. This surplus we can export without economic disturbance.

Second, we have for years exported to countries other than the Allies. By embargo of these shipments we can slightly increase the supplies available to the Allies.

Third, we can expand the area planted, and if our harvests are normal we can thereby enlarge the surplus for export through increased production.

Fourth, our normal consumption and waste of food are anywhere from 15 to 20% more than is necessary to maintain our own public health and strength, and we can in an emergency restrict the national consumption to our need, and thereby increase our exports.
